excluded from the growing bark, the practice of "mossing" has been more or less followed, consisting of binding upon the trunk, moss, leaves, straw, paper, rags, or similar substances. Bark so grown is denominated "mossed" (Fig. 110). By taking the bark off in vertical strips, which alternate with other strips left unbroken, the places so denuded being then mossed, a new covering is produced which is abnormally rich, and is known as *Renewed bark*. Both this and the mossed bark are classed among manufacturers' barks. Flat bark or *Tabla bark* is still occasionally called for by old-fashioned pharmacists. It was formerly a natural product, resulting from the exfoliation upon large trees of all but the bast-layer, this drying naturally in flat pieces. It is now produced to supply the limited demand by the artificial removal of the outer bark and drying flat under pressure. With mossing, renewing, and hybridization, other influences have combined to increase the alkaloidal yield of cultivated bark.

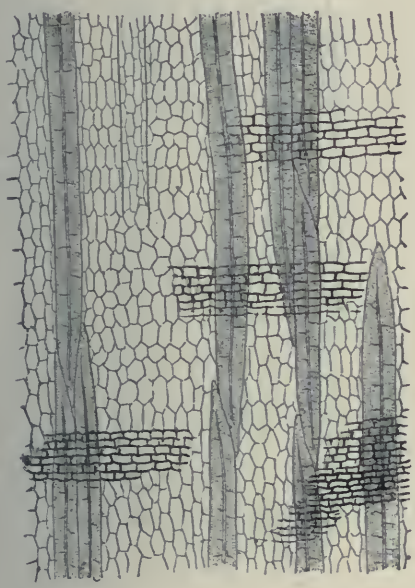
Description.—Cinchona.—In quills or curved pieces of variable size, usually 2 or 3, sometimes 5 Mm. ($\frac{1}{12}$ to $\frac{1}{8}$ or sometimes $\frac{1}{5}$ In.) thick; externally gray, preferably a bluish- or steel-gray, rarely brownish-gray (or cinnamon-brown when the outer bark is wanting), with numerous intersecting transverse and longitudinal fissures having nearly vertical sides; inner surface light cinnamon-brown, finely striate; fracture of the outer bark short and granular, of the inner finely splintery; powder light-brown or yellowish-brown; odor slight, aromatic; taste bitter and somewhat astringent.

Cinchona succirubra.—In quills or curved pieces of variable size, the bark 2 to 5 Mm. ($\frac{1}{12}$ to $\frac{1}{5}$ In.) thick; externally gray or gray-brown, more or less rough from longitudinal rows of warts, or from warty ridges which are sometimes fissured, and with few, mostly short and not intersected transverse fissures; inner surface reddish- or orange-brown, distinctly striate;

fracture short and granular in the outer, shortly and rather coarsely splintery in the inner bark; slightly odorous, bitter and astringent; powder reddish-brown.

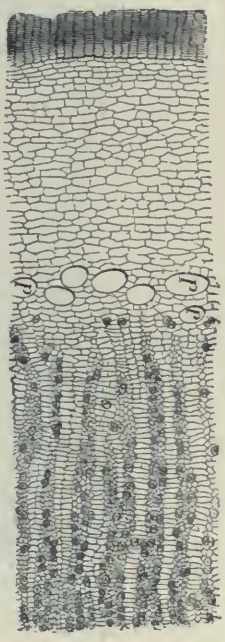
The distinguishing characteristic of calisaya bark (Fig. 108), in the entire condition, is its profuse reticulation of fine intersecting fissures with vertical sides and the absence of strong ridges. On transverse section (Fig. 112), its bast-fibers are seen to be scattered, mostly singly, a few in twos and threes. The medullary rays are narrow. On longitudinal

FIG. 111.



Calisaya bark: radial longitudinal section through liber, showing cinchona bast-fibers; magnified 60 diameters.

FIG. 112.



Young calisaya bark: transverse section; magnified 30 djameters.

section (Fig. 111), the bast-fibers are seen to be spindle-shaped and of medium size. Laticiferous ducts can be seen only in young bark. Its powder is of a yellow color, even though the entire bark was not so, as it usually is. Owing to the effects of hybridity, these microscopical characters are often not clear in the commercial bark of the present day.

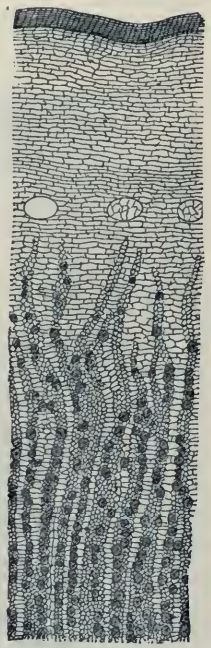
Red bark, being now quite scarce, is very frequently substituted in whole or in part by yellow bark. The practice is reprehensible, and is very readily detected by attention to the following characteristics: The distinguishing characteristics of red bark (Fig. 114) are its strong longitudinal ridging, these ridges, when very large, becoming longitudinally fissured, and the total or relative absence of other fissures, those which are present only rarely intersecting. On transverse section (Fig. 113), the bast-fibers are seen to be mostly aggregated in groups of 2 to 5, often more. A row of laticiferous ducts, usually more or less filled up with cells, can commonly be seen in the outer bark. On longitudinal section, the spindle-shaped bast-fibers are seen to be very coarse. These microscopical characters are but little modified by hybridity in red bark. Its powder is of a brownish-red, and is characterized by the strong tendency of its splintery bast-fibers to accumulate upon the surface.

In both species, the bast-fibers are simple—that is, not branched—and present a somewhat quadrangular appearance under the microscope, the cavity almost obliterated. Both species are conspicuously wanting in a peculiar variety of cell which occurs in many of the spurious barks. This is a form of stone-cell, laterally elongated, and frequently filled either with a brownish resinous-looking mass, or with granular crystals of calcium oxalate.

In both the official barks the alkaloids are found chiefly in the cortical tissue and to a considerable extent in the cork. The localization of the alkaloids becomes less characteristic in older barks. Whereas in the young bark, alkaloid is entirely wanting in the bast-layer, it is found richly deposited there in the ancient *tabla* or flat barks, those trees having lost by exfoliation all of their outer and middle layers.

Adulterants and Substitutes.—Adulteration and substitution of the cinchonas, once prevalent upon an enormous scale (see *History*), are now reduced to the smallest

Fig. 113.



Cinch. succirubra; transverse section of bark; magnified 30 diameters.

Fig. 114.

Red cinchona (Nat.).

proportions, except as to the selling of one of the leading kinds when another is called for. This is very common indeed. It results mostly through the ignorance of dealers, which is great and general; sometimes because there happens to be only one kind in stock. A single spurious bark is sold upon a rather large scale, though quite irregularly, as a fraudulent substitute for calisaya, under the name of *Yellow bark*. It is technically known as *Maracaibo bark* (Fig. 115), and its botanical derivation is uncertain. It occurs in flat, chip-like, warped pieces rarely so large as the hand, and about 3 to 9 Mm. ($\frac{1}{8}$ to $\frac{3}{8}$ In.) thick. Externally, it bears patches of a soft and friable silver-gray cork, easily scraped off with the finger-nail, and is of a dingy-yellow color where these are wanting. The inner surface is of a pale-yellow or light yellowish-brown and rather coarsely striate. Its fracture is short-splintery, yellowish, and shows a rather broad band of dark resin-tissue at the outside of the bast-layer. It is bitter from its resin, but contains only a trace of alkaloid.

Fig. 115.

Maracaibo bark (Nat.).

Fraudulent red barks have been offered which had been made by exposing inferior cinchona barks to ammonia, whereby cinchona-red is produced. Such barks were found by Thomas and Guignard (1882) to be deep-red in the parenchyma, to have pale-yellow bast-fibers, to yield red-colored infusions and decoctions, and these to give brown-red precipitates with Nessler's reagent, while the infusion of normal cinchonas gives a white precipitate with the same reagent; the chloroplatinate precipitate was found to contain 22 per cent. of Pt, while that with the cinchona alkaloids contains only between 16.8 and 17.8 per cent. of this metal.

Powdered cinchona is doubtless more or less adulterated with the residual stocks of the various inferior barks here named and those to be mentioned under *History.*

General Chemical Characteristics.—Grahe (1858) showed that if about 10 grains of the bark are heated in a test-tube, characteristic red vapors are evolved, which condense to an oily carmine-red liquid. Cinchona barks which have been deprived of their alkaloids by treatment with dilute acids do not show this reaction, but ligneous tissue which has been impregnated with a solution of cinchona alkaloids does so; and the reliability of the reaction is increased, according to Hesse, by incorporating an alcoholic tincture of cinchona with a powder of the same bark. This reaction, in connection with the presence of cinchona bast-fibers, noticed above, may be regarded as conclusive proof of the genuineness of cinchona barks; in the absence of the peculiar bast-fibers, merely as evidence of the presence of cinchona alkaloids; for Flückiger (1871) observed a white bark which contained cinchona bast-fibers and an alkaloid (*paytine*), but yielded a brown tarry instead of a red oily sublimate; and the latter is obtained from *Cuprea bark* (see below), which contains cinchona alkaloids, but is destitute of cinchona bast-fibers.

Constituents.—The important constituents of the official cinchona barks are their alkaloids and the cinchotannic, kinic, and kinovic acids, with one or more of which these alkaloids are combined. The alkaloids may be classed, according to their importance, as primary, secondary, and unimportant. The primary ones are quinine, quinidine, cinchonine, cinchonidine, and quinamine, all of which are considered elsewhere under these titles. The secondary alkaloids are hydroquinine, hydrocinchonidine, hydroquinidine, and homocinchonidine. The unimportant ones are dicinchonine, diquinidine, paricine, javanine, conquinamine, cincholine, etc., which are considered below. South American cultivated calisaya usually contains 3.5 to 4.5 per cent. of total alkaloid, occasionally up to 6 per cent.; that of the East Indies runs about a third richer. Ledger bark averages a little higher than calisaya, and is occasionally very rich, running up to 12 or even 14 per cent. Of this alkaloid, in both species, about two-thirds to four-fifths is quinine. Quinidine is next in importance, reaching sometimes to more than 0.5 per cent. With these are hydroquinine, hydroquinidine, and diquinidine. Cinchonine and cinchonidine are not present in appreciable amounts. Javanine and cincholine have been found in these two species.

Red bark ordinarily contains 5 or 6 per cent. of total alkaloid, occasionally 9 to 11 per cent. in Java cultivated bark, of which about one-fifth to two-fifths is quinine, with a relatively corresponding amount of quinidine. Cinchonidine is here the important alkaloid, reaching often to 3 or 4 per cent. Cinchonine is also abundant, but its percentage is very irregular. It is apt to be especially abundant in the root-bark. Other alkaloids found in red bark are quinamine, conquinamine, dicinchonine, hydrocinchonidine, homocinchonidine, and paricine.

The characteristic properties of the 4 principal cinchona alkaloids may be compared as follows:

	QUININE.	QUINIDINE.	CINCHONINE.	CINCHONIDINE.
Rotary power,	Lævogyre.	Dextrogyre.	Dextrogyre.	Lævogyre.
Soluble in water,	167 parts.	2000 parts.	3740 parts.	1680 parts.
Soluble in 80 per cent. alcohol,	6 "	26 "	133 "	20 "
Soluble in ether,	23 "	30 "	371 "	76.4 "
Sulphuric acid solutions,	Are fluorescent, 1 in 200,000.		Not fluorescent.	
Chlorine water and ammonia,	Emerald-green thalleioquin.		White precipitates.	
Chlorine water, ferrocyanide of potassium, and ammonia,	Dark-red solutions.		No coloration.	
Anhydrous sulphate, soluble in chloroform,	1000 parts.	19.5 parts.	60 parts.	1000 parts.
Hydriodate,	More soluble than next.	Soluble in 1270 parts water, or 110 parts alcohol.	Readily soluble in chloroform, alcohol, ether, and water.	Slightly in water, readily in alcohol.
Iodosulphate,	Green in reflected, colorless in transmitted light; soluble in 1000 parts boiling water.	Similar to preceding, but different tint.	Purplish-black; in transmitted light yellow or reddish.	Purplish garnet-red; in transmitted light like preceding.

The iodosulphates are obtained by dissolving the sulphates in weak alcohol, acidulating with sulphuric acid, precipitating with tincture of iodine, and crystallizing the precipitate from alcohol.

Hydroquinine ($C_{20}H_{26}N_2O_2$) melts at 168° C. (334.4° F.), and is soluble in ether.

Hydrocinchonidine (*Cinchamidine*, $C_{19}H_{24}N_2O$) is lævogyre, melts at about 230° C. (446° F.), and is sparingly soluble in chloroform, ether, and water.

Hydroquinidine (*Hydroconchinine*, $C_{20}H_{26}N_2O_2$) melts at 167° C. (332.6° F.); is dextrogyre, and soluble in hot alcohol and in chloroform, with difficulty in ether; and yields fluorescent solution and thalleioquin, like quinine.

Homocinchonidine ($C_{19}H_{22}N_2O$) is lævogyre, and its sulphate crystallizes with 6 molecules of water in delicate needles of a gelatinous aspect and which fuse near 30° C. (86° F.). Its anhydrous monobasic sulphate yields homocinchonicine.

Paricine ($C_{16}H_{18}N_2O$) is pale-yellow, amorphous, soluble in ether, and converted by strong nitric acid into a dark-green resinous mass.

Javanine is readily soluble in ether, and dissolves in dilute sulphuric acid with an intense yellow color.

Conquinamine is isomeric with quinamine, and melts at 123° C. (253.4° F.).

Quinamidine is isomeric with quinamine, from which it is obtained by boiling with dilute sulphuric acid.

Quinamicine is obtained by heating quinamine to 100° C. (212° F.), and is also isomeric.

Protoquinamicine is similarly obtained at 120° C. (248° F.).

Apoquinamine is obtained by treating quinamine or conquinamine with concentrated hydrochloric acid.

Cincholine occurs as a pale-yellow liquid, soluble in ether, alcohol, and chloroform and nearly tasteless in neutral solutions. Flückiger suggested that it may have originated from the hydrocarbons employed in manipulation.

The relation of the cinchona alkaloids, of both the official and unofficial barks, to each other in regard to their ultimate composition will be observed from the following:

$C_{23}H_{26}N_2O_4$: cusconine and aricine.

$C_{21}H_{24}N_2O$: paytine.

$C_{20}H_{26}N_2O_2$: hydroquinine, hydroquinidine (hydroconchinine).

$C_{20}H_{24}N_2O_2$; quinine, quinidine, quinicine, and $2(C_{20}H_{24}N_2O_2) - H_2O$: dicinchinine.

$C_{19}H_{24}N_2O_2$: quinamine, conquinamine, quinamidine, and quinamicine.

$C_{19}H_{24}N_2O$: hydrocinchonine (cinchotine), hydrocinchonidine (cinchamidine), and cinchonamine.

$C_{19}H_{22}N_2O_2$: homoquinine, apoquinine.

$C_{19}H_{22}N_2O$: cinchonine, cinchonidine, cinchonicine, apoquinamine, homocinchonine, homocinchonidine and homocinchonicine, and $2(C_{19}H_{22}N_2O)$: dicinchonicine.

$C_{17}H_{20}N_2O$: protoquinamine.

$C_{16}H_{18}N_2O$: paricine.

Not analyzed: cusconidine, cuscamine, cuscamidine, javanine, cincholine.

Other Constituents.—*Kinic* or *quinic acid* (*Chinasäure*, $C_7H_{12}O_6$) is found in cinchona barks and in many plants of the natural orders *Rubiaceæ*, *Vacciniaceæ*, etc. According to Hesse, it is not present in Cuprea bark. In the preparation of quinine it is contained in the filtrate from the precipitated alkaloids. It appears to be present to the amount of 5 to 7, or even 9, per cent., and when pure forms transparent colorless oblique rhombic prisms which fuse at 162° C. (323.6° F.), are readily soluble in water, less in strong alcohol, and slightly in ether. On treating it or one of its salts with manganese peroxide and sulphuric acid it yields, besides carbon dioxide and formic acid, a golden-yellow crystalline sublimate of *kinone* or *quinone*, $C_6H_4O_2$. On being heated with hydriodic acid it is converted into benzoic acid, and when fused with potassium hydroxide it yields protocatechuic acid.

Kinovic or *quinovic acid* ($C_{24}H_{38}O_4$) is met with in the East Indian barks, and forms a tasteless shining crystalline powder which is insoluble in water and chloroform, slightly soluble in ether and cold alcohol, but soluble in alkalies and alkaline carbonates. It was discovered by Hlasiwetz (1859) as a product of the decomposition of kinovin.

Kinovin or *quinovin* ($C_{30}H_{48}O_8$) was discovered by Pelletier and Caventou (1821), and at first named *quinovic acid*, afterward *quinova bitter*; its glucosidal nature was determined by Hlasiwetz (1859). It is an amorphous mass of a disagreeable bitter taste, sparingly soluble in cold water, soluble in ether, acetone, chloroform, fixed and volatile oils, and freely soluble in alcohol. Its compounds with the alkalies, lime, and magnesia are soluble in water. Its solution in alcohol, treated with hydrochloric acid gas, yields kinovic acid and uncrystallizable mannitan (kinovin sugar), $C_6H_{12}O_5$. It has been found in different cinchona barks in quantities varying between 0.11 and 1.74 per cent., and is contained also in the barks of *Esenbeckia febrifuga* and *Buena magnifolia* (*China* or *Cuina nova*, hence its name).

Cinchotannic (or *quinotannic*) *acid* appears to be present in the best cinchona barks to the amount of 2 to 4 per cent. By treating the decoction with magnesia, precipitating the filtrate with lead acetate, decomposing with hydrogen sulphide, and repeating this process, it is obtained as a pale-yellow mass of an acidulous and astringent taste, readily soluble in water, alcohol, and ether, turning greenish with salts of iron, and yielding cinchona-red with alkalies or on being boiled with water. According to Rembold (1867), by boiling with dilute sulphuric acid it is split into sugar and

Cinchona-red, $C_{28}H_{22}O_{14}$, which is nearly insoluble in water and ether, but dissolves readily in alkaline solutions and alcohol. It yields protocatechuic acid when treated with fusing potassa. Though contained in all cinchona barks, those having a red color contain it in largest proportion,—thick red bark containing more than 10 per cent.

The odor of cinchona barks is due to a minute quantity of a butyraceous *volatile oil*, which was first obtained by Fabbroni. Trommsdorff obtained 2 grains from 20 pounds of pale bark. The remaining constituents are of no importance either medicinally or pharmaceutically; they comprise starch, gum, sugar, resin, fat, wax, ammonium salts, and calcium oxalate, all in small quantities. Kerner's *cinchocerotin*, $C_{27}H_{48}O_2$, according to Helms (1883), appears to be related to betulin. The ash amounts to between 1 and 3 per cent., and consists mostly of the carbonates of calcium and potassium.

History.—Cinchona bark and its medicinal properties became known to science before the plants which produced them. This knowledge appears to have been possessed by the natives at an earlier period, though they made little use of it, and they were able to render assistance by indicating the most active species. The new medicine was received in Europe without either interest or favor, and these were not awakened until it had effected a notable cure of royalty in the person of the Countess de Chinchon. With this favor, antagonism also developed, and proved to be remarkably strong, persisting for generations. Yet the drug gained steadily and surely in favor, and at length came into the most general use; so much so as to make it of first importance among vegetable drugs. Its collection became the most important industry of the producing countries, involving extensive special legislation and much political intrigue and corruption, while its commerce engaged the close attention of the most important business interests. The use of *C. officinalis*, the bark first discovered, was followed rapidly by the discovery of other species, several of them superior, a much larger number inferior to it. Steady and excessive collection of the better kinds, without any accompanying measures, honestly designed and executed, toward preserving a future supply, resulted in very great scarcity, and finally in exorbitant prices, as much as 4 dollars per pound being charged for good bark, between the years 1880 and 1885, and 8 and 9 dollars per ounce for quinine. These high prices stimulated to the utmost the production of substitutes, both legitimately and fraudulently employed. Every cinchona bark that contained any quinine was eagerly collected. Even related barks, not of this genus, were utilized, some of them containing alkaloids or other bitter constituents, others without value except for fraudulent substitution. Since selection by assay was then scarcely practised, it became necessary to identify all of these products by physical examination, and, since some of the worthless ones closely resembled the better, this involved great skill and experience. A distinct class of experts thus grew up whose services were highly valued and who became persons of great importance.

Two highly important results developed from this condition of affairs. The first was an attempt to corner the supply of the quinine-yielding barks; the second was the introduction of the trees to cultivation. The former object was undertaken by buying up and accumulating in London all obtainable supplies. So extensive was this operation that the resulting accumulations are not yet exhausted, and still affect commerce to some extent, as will be shown presently. It bade fair to become one of the most successful operations of its kind until, through the discovery and marketing in immense quantities of Remijia or Cuprea bark, the corner was broken. The market value of much of the accumulated supply sank below cost and never recovered, until now it amounts to almost nothing.

Long before the period of greatest scarcity, intelligent foreigners had become alarmed by the rate of extermination in progress, and the apathy, or venality, of the administration in the producing countries, which prevented the execution of protective measures, and had come to realize the necessity for transplanting the producing industry to some country where it could be controlled. The first efforts were made by La Condamine, in 1737, but his plants were lost through shipwreck. Subsequent efforts were made by the

Dutch and English, and some of them proved successful. Through imperfect knowledge of the plants, much time and money were wasted in the propagation and culture of worthless species, but many valuable ones were also introduced, the best of them being, besides the above-named official ones, *C. officinalis* L., in several varieties, and which afterward entered into the production of a number of hybrids, *C. micrantha* R. et P., *C. lancifolia* Mutis, and *C. scrobiculata* H. et B. At first, the products of all these were in great demand, but as the supply increased and prices declined, opportunity was offered for increasing the stocks of the better kinds to the neglect of the others, with the final result stated under *Origin*. After the establishment of plantations in the East Indies, and when the native supply had become so far exhausted that even seeds for propagation could not be secured, the native countries, especially Bolivia (through the activity of foreigners residing there), obtained supplies of seeds from the foreign plantations and established cultivation. These plantations were for some years very profitable, but at length prices declined so far that the marketing of the South American barks, involving expensive transportation upon the backs of men over the mountains, precluded a profitable trade, and supplies have now almost ceased to come from there. The South American cultivated bark has always been more subject to inferiority, due to hybridity with the worthless species which abound in the vicinity of the plantations, especially *C. ovata* R. et P. (*Cocola*) and *C. Josephiana* Willd. (*Pajinal*), or *C. Calisaya*, var. *Josephiana*, as it was long known. Foreign barks are also subject to such hybridity, and probably most of the bark commonly considered as thoroughbred is of mixed parentage, yet this parentage is itself valuable, and instead of degrading, has enriched much of the bark.

Aside from this effect of cultivation upon the bark market, concurrent developments have brought about important modifications in manufacturing. The British Indian Government, desiring to avoid the heavy expense of exportation of bark and reimportation of alkaloid, has successfully established manufacturing, especially of an impure alkaloidal mixture called *Febrifuge*, immediately at the plantations. This febrifuge sometimes represents the alkaloidal constituents of red bark, sometimes the residual alkaloids of the quinine barks after the removal of the quinine, more often a mixture from these two sources. *Quinetine* was a substitute manufactured in London in imitation of febrifuge. More recently, the Dutch planters in Java have established quinine manufactories which bid fair to render them to a great extent independent of the bark market.

Assay of Cinchona.—Cinchona, in No. 80 (or finer) powder, 15 Gm.; ether, specific gravity not above 0.720 at 25° C. (77° F.), chloroform, ammonia-water, distilled water, normal sulphuric acid, each a sufficient quantity. Introduce the cinchona into an Erlenmeyer flask or bottle of about 200 Cc. capacity, and add a mixture of 125 Cc. of ether and 25 Cc. of chloroform; then insert the stopper securely, shake the flask vigorously, and allow it to stand for 10 minutes. Then add 10 Cc. of ammonia-water, and allow it to stand for 5 hours, shaking at frequent intervals (or continuously with the aid of a mechanical shaker). Next add 15 Cc. of distilled water, and shake the flask vigorously for a few minutes, so as to cause the powder to settle readily on standing. When the supernatant fluid is quite clear, decant into a measuring flask, or cylinder, exactly 100 Cc. of the supernatant liquid (representing 10 Gm. of cinchona), transfer this to a separator, and add 15 Cc. of normal sulphuric acid, or sufficient to make the liquid distinctly acid. Shake the separator vigorously for 1 minute, and allow the two layers of liquid to separate completely. Draw off the lower aqueous layer into a flask. Then add 5 Cc. of normal sulphuric acid and 5 Cc. of distilled water to the separator, and shake it vigorously for about 1 minute, allow the liquids to separate as before, and again draw off the lower aqueous layer into the flask. Repeat the operation, using 5 Cc. of distilled water in the separator (without acid), drawing off the aqueous liquid into the flask. Filter the combined acid liquids into a measuring cylinder, and wash the filter and flask with enough distilled water to make the contents of the cylinder measure exactly 50 Cc. Pour half (25 Cc.) of the acid liquid into a separator marked No. 1, and the remaining half (25 Cc.) into another separator marked No. 2, which set aside.

1. *For Anhydrous Cinchona Alkaloids.*—To separator No. 1 (see above) add 25 Cc. of a mixture of chloroform 3 volumes and ether 1 volume, and add 5 Cc. of ammonia-water, or sufficient to render the liquid alkaline. Insert the stopper and shake the separator carefully for 3 minutes, and then draw off the lower layer into a tared flask or beaker. Add 20 Cc. more of the chloroform-ether mixture to the separator, insert the stopper, and shake the liquid carefully for 2 minutes, again drawing off the lower layer into the tared flask. Repeat the operation with 10 Cc. of chloroform, and draw this off into the tared flask. Reject the aqueous liquid in the separator, and with the aid of a water-bath evaporate the chloroform-ether solution in the tared flask or beaker, slowly and carefully, to dryness. Add 3 Cc.

of ether to the dry residue, and again evaporate to dryness. Then place the flask or beaker in an air-bath and heat at 110° C. (230° F.) until the weight after cooling remains constant. The weight of the residue multiplied by 20 will give the percentage of anhydrous cinchona alkaloids (total alkaloids) in the cinchona.

2. *For Ether-soluble Alkaloids.*—To separator No. 2 (see above), containing the other 25 Cc. of acid liquid, add 25 Cc. of ether and 5 Cc. of ammonia-water, or sufficient to render the liquid slightly alkaline. The temperature of the liquid should be kept below 15° C. (59° F.) by cooling it if necessary. Shake the separator moderately for 2 minutes, and allow the liquid to stand for 10 minutes at 15° C. (59° F.); after the liquids have separated, draw off and reject the lower aqueous layer and transfer the ethereal liquid to a tared beaker. Add 5 Cc. more of ether to the separator, rinse carefully, and add the rinsings. Evaporate the ether carefully by the aid of a water-bath, dry the beaker and contents in an air-bath at 120° C. (248° F.) for two hours, cool, and weigh. The weight of the residue multiplied by 20 gives the percentage of the anhydrous ether-soluble alkaloids contained in the cinchona.

Note.—Anhydrous ether-soluble alkaloids include quinine, quinidine, and cinchonidine.

Pharmaceutical Preparations.—Compound Tincture of Cinchona, U. S. P.; Detannated Tincture of Cinchona, N. F.; Detannated Elixir of Cinchona, N. F.; Elixir of Cinchona, N. F.; Elixir of Cinchona and Hypophosphites, N. F.; Elixir of Cinchona and Iron, N. F.; Elixir of Cinchona, Iron, and Bismuth, N. F.; Elixir of Cinchona, Iron, and Calcium Lactophosphate, N. F.; Elixir of Cinchona, Iron, and Pepsin, N. F.; Elixir of Cinchona, Iron, and Strychnine, N. F.; Elixir of Cinchona, Iron, Bismuth, and Strychnine, N. F.; Elixir of Cinchona, Pepsin, and Strychnine, N. F.; Fluidextract of Cinchona, U. S. P.; Tincture of Cinchona, U. S. P.

Action and Uses.—The action and uses of cinchona will be found described in the article dealing with the various alkaloids of this bark, notably under the heading Quininæ Sulphas.

Unofficial and Allied Barks and Products.—The genus *Cinchona* contains about 40 species, natives of the eastern Andes from about 18° south to 10° north. Besides the bark, their wood, leaves, and fruits have been found to contain unimportant amounts of their peculiar alkaloids. The barks of most of them have entered commerce, though many of them only as substitutes or adulterants recognized as worthless. Besides the cinchonas, related and similar barks have also been collected. Of these, nearly all are worthless, but at least one, *Remijia*, contains considerable quinine. In all of them our interest is chiefly historical. It would be folly to cultivate them when rich barks can be produced with equal ease and expenditure, while in the wild state, growing as they do in remote and inaccessible regions, the cost of collecting and marketing is greater than that of producing the cultivated varieties. The pharmaceutical use of most of them is everywhere barred by official requirements and intelligent custom, while it is unprofitable to extract their quinine, owing to the relatively large amount of bark which must be worked over. In spite of these facts, however, there are various reasons why they possess some degree of commercial interest.

Fig. 116.

Officinalis bark, Jamaica-grown: small quill (Nat.).

C. officinalis (*Cinchona pallida; Cinchonæ pallidæ Cortex; Cortex chinæ fuscus; China fusca, grisea, pallida*, or *cinerea.—Pale Peruvian bark, Loxa, Huanuco* (in part), *Cuenca, Guayaquil* or *Crown bark*, E.; *Quinquina gris de Loxa*, Fr.; *Braune* (*Graue*) *Chinarinde, Loxarinde, Kronchina*, G.; *Quina gris de Loja, Quina charhuarguera*, Sp.) is probably of more importance than all the other unofficial barks combined. It is fairly rich and its alkaloid is of good quality. It has been official up to a recent date, and is now excluded solely by reason of its deficient alkaloidal percentage, although its preparations have become favorites with many physicians. It is especially valued in France, Spain, and other countries of southern Europe. There are still quite extensive stocks of it in various plantations, and there is a small but steady collection in the wild state. It was the first species discovered, and upon it the genus was founded. It comes from Ecuador, and has been introduced to cultivation in nearly all cinchona plantations, and in Jamaica has escaped and become thoroughly naturalized. It presents a number of distinct forms or varieties, if indeed they be not species, and their barks exhibit very marked differences. The wild forms are all in quills rarely thicker than a man's thumb. Under cultivation, it grows as a tree, and it seems almost certain that this must be due to hybridization with other species.

Description.—Typical pale cinchona occurs in well-formed quills of variable length, usually 1 to 1.5 Cm. ($\frac{2}{5}$ to $\frac{3}{5}$ In., rarely reaching 1 In.) in diameter, and the bark mostly 2 to 4 Mm. ($\frac{1}{12}$ to $\frac{1}{8}$ In.) thick, always notable for its thickness as compared with the size of the quill; periderm varying from gray-brown (in the *Huanuco*) to nearly black

(in the best *Loxa*), longitudinally wrinkled, the wrinkles rather strong but short, and irregular in direction, commonly shaggy with gray and yellowish-green lichens, without fissures, or sparsely transversely fissured, the fissures short and of a gaping character, dot intersecting; inner surface of a light or yellowish rust-brown, nearly smooth; fracture short, the fibrous zone narrow, the bast-fibers rather few, mostly arranged in groups of from 3 to 6, of medium size; stone-cells rare, laticiferous ducts wanting except in the youngest bark; taste only moderately bitter. Powder pale-brown.

As this bark now comes to us from cultivated sources, it is in very much larger quills, apparently coming from good-sized trees, and preserves its relative thickness. It is much more fissured, its inner surface and powder more reddish, and its bast-fibers are wanting in the specific characters. For these reasons and because of its very different alkaloidal yield, it appears almost certain that it is a hybrid of *C. officinalis* with one or more other species.

Fig. 117.

Officinalis: forest-grown and lichen-covered (Nat.).

Fig. 118.

Brown Huanuco bark (Nat.).

The distinguishing characteristic of this bark is found in the character of its fissures, if these be present. They are never in the pure bark so numerous nor so much intersecting as in calisaya, but are more so than in the rubra. Most important are their slanting sides, the width much greater at the top than at the bottom, imparting a gaping appearance to them. As the bark grows in its nativity, there is the greatest difference in its covering of lichens. Those lots which are shaggy from this growth have always been preferred, and examination shows that they are uniformly richer.

The different varieties of pale bark differ greatly in composition, the total amount of alkaloid varying from about 1 to 3½ or even 4 per cent. From one-half to two-thirds of this alkaloid is quinine. Indian-grown bark has been reported to contain upward of 8 per cent. of total alkaloid, but there is no sufficient evidence that this was pure *officinalis*.

Other cinchona barks formerly important articles of commerce, but now scarcely ever seen, may be briefly mentioned. *Fibrous Calisaya* was derived from *C. lancifolia* Mutis and *C. scrobiculata* H. et B., and was so called because of its long-fibrous fracture. It is intermediate in color between succirubra and calisaya, but the cork is very soft. It contains large stone-cells. That of *C. scrobiculata* contains laticiferous ducts, that of *C. lancifolia* does not. Somewhat similar was that of *C. Boliviana* Wedd., but this more closely resembled calisaya, and was often called a "gray bark." It showed large whitish spots on fracture. *Gray* or *Huamalies bark* was mostly the product of *C. micrantha* R. et P., a Bolivian species. It was of an ashy-gray, had no or very few stone-cells and no laticiferous ducts, and its medium-sized bast-fibers were mostly in pairs or threes, occasionally in groups of 5 to 8. Two Bolivian barks, quite worthless, were of commercial importance as frequent admixtures of gray and calisaya barks. One was *C. ovata* or *Arica bark*, the *Cocola* of the natives, ashy-gray, very thin considering the large size of the quill, and disposed to wrinkle. It contained *aricine* or *cinchovatine* ($C_{23}H_{36}N_2O_4$), which is crystalline and gives a dark-green solution with nitric acid. The other was *C. Josephiana* Wedd., long called var. *Josephiana* of *C. Calisaya*, an entirely worthless bark, called *Pajinal* by the natives. It grows upon a large shrub, and is very thin and much wrinkled in drying, and is usually of a purplish-gray color. *Cusco bark*, from *C. pubescens* Vahl, has a pale brownish-yellow, usually warty periderm, cinnamon-colored within and of a coarse-splintery fracture. It contains *cuscovatine*, very similar to aricine, but many of its salts take a gelatinous form. Other alkaloids reported in it are *cusconadine* and *cuscamine*. *Pitaya bark* was from *C. Pitayensis* Wedd., and had a smooth, ochre-colored periderm, a reddish-brown inner surface, and a short-splintery fracture. Some Pitaya bark is said to have come from a species of *Ladenbergia*.

Of related barks not in the genus *Cinchona*, by far the most important was *Cuprea bark*, so called from its coppery-red surface, the product of *Remijia Purdieana* Wedd. and *R. pedunculata* Tri. (*Cinchona* P. Karst.), of central and southern Colombia. It is in quills or curved pieces with a brown-red inner surface, externally with fragments of gray or brownish cork, and copper-red in the interior; the transverse fracture is coarsely granular, the longitudinal fracture rather splintery; the transverse fracture shows thick-walled cork-cells;

sometimes scattered laticiferous ducts, many transversely elongated stone-cells, both in the outer bark and bast-layer, and in the latter numerous wavy medullary rays and radial lines of closely packed, thin, elongated, obtuse bast-fibres, with the central cavity usually large; these bast-rays are less numerous in the inner than in the outer portion of the liber. The bark is very compact, hard, and heavier than water; that from southern Colombia is denser, more compact, and shows a more horny fracture. Cuprea bark varies considerably in the amount of alkaloids, which in bark from high elevations sometimes reaches 3 or even 6 per cent., or 2 per cent. of quinine, the remainder being quinidine and cinchonine, sometimes cinchonamine, but never cinchonidine. Koerner obtained from the mother-liquor resulting from the extraction of quinine from Cuprea bark a considerable amount of caffeate of quinine, yielding caffeic acid, about 0.5 per cent., practically identical with that obtained by splitting up caffeotannic acid derived from coffee.

Peckolt states that the bark of *R. ferruginea* DC. is used by the Brazilian natives in the treatment of malaria, and a number of other species are similarly used.

Most of the wholly spurious barks were obtained from trees belonging to the genera *Cascarilla, Ladenbergia, Nauclea, Buena,* and *Exostemma;* some of these are quite similar to cinchona barks in appearance, while others have not the slightest resemblance to them. In those barks most nearly allied to cinchona, a cinchona bast-fiber is occasionally met with, but nearly all the bast-fibers have large central cavities. Others (*Nauclea*) have the thin fibers nearly filled up, but regularly arranged in radial and tangential rows. Grahe's test—and, more reliable still, the microscope—will at once prove their distinctiveness.

Pinckneya Pubens Mx. (*Cinchona caroliniana* Biret) is a small tree growing in swampy localities from South Carolina to Florida. The bark is employed as a tonic and febrifuge under the name of *Georgia bark.* Farr claims having detected a considerable amount of cinchonine in the bark (Porcher, *Resources,* p. 442), which is probably incorrect, though the plant is likely to contain an alkaloid. *Arariba bark,* from *P. rufescens,* contains *aribine* ($C_{23}H_{20}N_4 + 5H_2O$), crystalline like its salts, neutral, optically inactive, and with a melting-point of 229° C. (442.2° F.).

Crossopteryx febrifuga Benth. (*C. Kotschyana* Fenzl.) is a tree of tropical Africa having febrifuge properties, and, like the preceding, belonging to the suborder *Cinchoneæ.* Hesse (1879) isolated from the bark 0.018 per cent. of an amorphous white liquid alkaloid, *crossopterine,* which is easily soluble in alcohol, ether, and ammonia, and yields bitter salts. The aqueous infusion of the bark shows blue fluorescence, which disappears on acidulation with sulphuric acid, and even after boiling reappears on the addition of an alkali.

Pambotana bark, from a leguminous tree of Mexico, probably a *Dalbergia,* has been proposed as a cinchona substitute. It contains neither alkaloid nor glucoside.

CINCHONIDINA.—Cinchonidine.

Cinchonidine, F.; *Cinchonidin,* G.[1]

Formula, $C_{19}H_{22}N_2O$. Molecular weight, 292.03.

An alkaloid obtained from the bark of various species of cinchona. Cinchonidine was discovered by Pasteur (1853) in commercial quinidine, and its present formula, $C_{19}H_{22}N_2O$, definitely established by Skraup (1879). It is an isomer of cinchonine. The cultivated British-India and Javanese red barks, and the Columbian (South American) varieties yield large proportions of the alkaloid. The free alkaloid is not official.

Preparation.—The mother-liquors obtained in the manufacture of quinine sulphate are precipitated with a solution of Rochelle salt, and the precipitated tartrates washed with water and then dissolved in dilute hydrochloric acid. The solution is made strongly alkaline with water of ammonia and the precipitated alkaloids exhausted with ether until the precipitated alkaloid fails to give the thalleioquin test (absence of quinine and quinidine). The residual alkaloid, *cinchonidine,* is dissolved in dilute hydrochloric acid, again precipitated by water of ammonia, and after washing with water crystallized from alcohol.

Properties.—Cinchonidine crystallizes from alcohol in lustrous short anhydrous prisms, or from dilute alcohol in thin plates. It has a bitter taste, melts at 202.5° C. (396.5° F.), and congeals again to a crystalline mass at 190° C. (374° F.). It is soluble in about 1600 parts of cold water, in about 20 parts of alcohol, and 188 parts of ether. The presence of quinine increases the solubility in ether. It is easily soluble in amyl alcohol and chloroform, and slightly soluble in ammonia. It is strongly lævorotatory, the specific rotatory power being affected by the concentration and the nature of the solvent. The maximum rotation in alcoholic solutions occurs in 50 per cent. alcohol and the minimum in absolute alcohol, while the least variation

[1] Also termed in German Cinchonidin II., α-Chinidin.

occurs in aqueous solutions (C. A. Schuster, *Monatsh.*, 14, 573–595). Cinchonidine is a strong base, of alkaline reaction; bibasic in valency, and forms basic, neutral, and acid salts. The solutions of its salts are precipitated by the alkali hydroxides and carbonates, and the general reagents for alkaloids. Its crystalline forms and microscopic characteristics distinguish it from homocinchonidine (Behrens, *Fr. Z. f. A. C.*, 35, pp. 133–143). It is separated from the other cinchona alkaloids by precipitating with normal tartrate solution and following the course for its preparation indicated above.

Action and Uses.—Cinchonidine and its various salts have been employed as substitutes for the quinine salts in those diseases in which the latter drugs are indicated. It is less powerful than quinine and must be given in larger doses.

UNOFFICIAL SALTS OF CINCHONIDINE.

Cinchonidinæ Hydrobromidum.—*Cinchonidine hydrobromide (basic). Cinchonidinbromhydrat.* $C_{19}H_{22}N_2O.HBr. + H_2O$. Molecular weight, 390.27.—It is prepared by adding a hot solution of 4.5 parts of crystallized barium bromide in 40 parts of water to a hot solution of 10 parts of cinchonidine sulphate in 60 parts of water, filtering out the precipitated barium sulphate and concentrating the filtrate and crystallizing. It forms long colorless needles soluble in about 40 parts of cold water, and easily soluble in hot water.

Cinchonidinæ Hydrobromidum Acidum. *Cinchonidine hydrobromide. Saures, bromwasserstoffsaures Cinchonidin.* $C_{19}H_{22}N_2O.2HBr + 2H_2O$. Molecular weight, 488.51.—It is prepared by adding a solution of 9 parts of crystallized barium bromide in 25 parts of water to a hot solution of 10 parts of cinchonidine sulphate in about 50 parts of water and 8.1 parts of dilute sulphuric acid (specific gravity 1.112), filtering, and after concentrating the filtrate sufficiently allowing to crystallize. Long, slightly yellowish crystals, soluble in 6 parts of water.

Cinchonidinæ Hydrochloridum.—*Cinchonidine hydrochloride (basic). Cinchonidinhydrochlorid.* $C_{19}H_{22}N_2O.HCl + H_2O$. Molecular weight, 346.09.—It may be prepared by dissolving 10 parts of cinchonidine in the proper equivalent of dilute hydrochloric acid (34.1 Cc. of normal test-solution) and crystallizing the solution. Lustrous, monoclinic pyramids or octahedra, soluble in about 20 parts of water, and soluble in alcohol and chloroform.

Cinchonidinæ Hydrochloridum Acidum.—*Cinchonidine hydrochloride. Saures Cinchonidinchlorhydrat.* $C_{19}H_{22}N_2O.2HCl + H_2O$. Molecular weight, 382.27.—It is easily prepared by dissolving 10 parts of cinchonidine in 68.2 Cc. of normal test-solution of hydrochloric acid and crystallizing. Long, colorless, monoclinic crystals, soluble in water and alcohol.

Cinchonidinæ Salicylas.—*Cinchonidine salicylate. Salicylsaures Cinchonidin.* $C_{19}H_{22}N_2O.C_7H_6O_3$. Molecular weight, 429.04.—100 parts of finely pulverized cinchonidine and 43.51 parts of pure salicylic acid are mixed in about 2500 parts of distilled water and boiled for several hours under a reflux condenser. The solution is then set aside to crystallize. The mother-liquor may be concentrated for a further crop of crystals. The crystals are insoluble in cold water, but easily soluble in alcohol.

Cinchonidinæ Tannas.—*Cinchonidine tannate. Gerbsaures Cinchonidin.*—10 parts of pulverized cinchonidine and 17 parts of tannic acid are mixed and ground in a porcelain or glass mortar with 25 parts of alcohol, and the resulting mass allowed to dry spontaneously A white to yellowish-white powder, insoluble in water and difficultly soluble in alcohol.

CINCHONIDINÆ SULPHAS, *U. S.*—Cinchonidine Sulphate.

Cinchonidinum sulfuricum.—*Sulphate of cinchonidine*, E.; *Sulfate de cinchonidine*, Fr.; *Cinchonidinsulfat*, G.; *Solfato di cinconidina*, It., Sp.

Formula, $(C_{19}H_{22}N_2O)_2H_2SO_4 + 3H_2O$. Molecular weight, 735.05.

The neutral sulphate of an alkaloid prepared from the bark of several species of Cinchona.—U. S.

Origin.—Certain cinchona barks, notably those obtained from *Cinch. succirubra* Pavon, *Cinch. officinalis* Hooker, cultivated in India, and the South American barks from *Cinch. lancifolia* Mutis, and *Cinch. tacujensis* Karsten, contain cinchonidine. A very similar alkaloid, called *homocinchonidine*, is rarely, and then only in minute quantities, found in these barks; but in certain lots of South American red barks the second alkaloid named is present in considerable proportion, wholly or partly replacing the first named (Hesse, *Berichte*, 1881, p. 1890). These alkaloids were at first described by Winckler (1847) and others as *quinidine* or *chinidine*, a name which was retained for them long after Pasteur's investigations in 1853 by several chemists, and for many years by several manufacturers in Germany and Austria.

Preparation.—In the process of manufacturing quinine sulphate, and while recrystallizing this salt, mother-liquors are obtained containing mainly cinchonidine sulphate. On concentrating the solutions the salt crystallizes and requires purification by recrystallization from water in order to obtain it free from quinine and quinidine sulphate. Formerly it could be prepared from commercial chinoidine, which sometimes contained notable quantities of this alkaloid. It may be prepared by dissolving 10 parts of cinchonidine in about 150 parts of water and adding just sufficient dilute sulphuric acid to neutralize it, then evaporating to about 100 parts and crystallizing.

Properties.—Commercial cinchonidine sulphate resembles quinine sulphate in appearance. It occurs as white, glistening, silky needles or prisms, which are permanent in the air, without odor, and have a very bitter taste. When crystallized from alcohol it contains 2 molecules of water of crystallization, if from dilute aqueous solutions 3 molecules, and if from concentrated solutions 6 molecules of water. It is soluble at 25° C. (77° F.) in 63 parts of water, 72 parts of alcohol, 900 parts of chloroform, or 4400 parts of ether; at 80° C. (176° F.) in 21 parts of water, and at 60° C. (140° F.) in 32 parts of alcohol (U. S.). Also soluble in 70 parts of water or 1316 parts of chloroform at 15° C. (59° F.), and in 1.42 parts of boiling water or 8 parts of boiling alcohol. The salt dissolves readily in diluted acids, the solutions being free from fluorescence. Its solubility in ether and chloroform is increased by the presence of the sulphates of other cinchona alkaloids. "When heated to 100° C. (212° F.) cinchonidine sulphate loses its water of crystallization, and at 203° C. (397.4° F.) it darkens, and

FIG. 119.

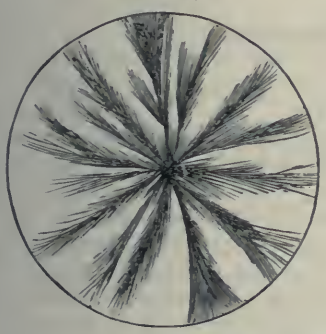


FIG. 120.

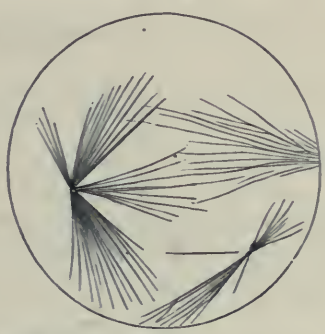


Cinchonidine sulphate with KSCy: microscopic crystals.

then melts at 205.3° C. (401.5° F.). At higher temperatures it ignites and is consumed without leaving a residue. The aqueous solution is neutral or only faintly alkaline to phenolphthalein or litmus test-solutions, and is lævogyrate. It yields with barium chloride test-solution a white precipitate, insoluble in hydrochloric acid. On adding ammonia-water to the aqueous solution of the salt, a white precipitate (cinchonidine) is produced, which is but slightly soluble in ammonia, but which, when freshly precipitated, dissolves in 10 parts of ether, the greater part afterward separating in crystals." —U. S. On mixing a drop of an aqueous solution of the salt with a drop of solution of potassium sulphocyanate, microscopical crystals are formed, which are either feathery and stellately arranged around a centre, or are spike-like and united in star-like or fan-shaped groups. According to Hesse (1878), cinchonidine sulphate is so completely precipitated by an excess of potassium sulphocyanate that the filtrate is not rendered turbid by ammonia.

Homocinchonidine sulphate has the composition and properties described above, but crystallizes either in dull-white prisms or in delicate white needles, requires at 22° C. (71.6° F.) 69 parts of water for solution, and its aqueous solution, saturated at 50° C. (122° F.), congeals on cooling to a gelatinous mass consisting of delicate crystals and enclosing the mother-liquor, while under the same conditions the cinchonidine salt yields glossy needles, from which the mother-liquor may be readily drained. Both salts on being treated with potassium permanganate yield *cinchotenidine*, $C_{18}H_{20}N_2O_3$, which was discovered by Skraup (1879), crystallizes with $3H_2O$ in colorless prisms, melts at 256° C. (492.8° F.), and is not fluorescent in acid solutions (Hesse, 1881).

Tests.—The solution of the salt (1 in 1000) in dilute sulphuric acid should not show more than a slight blue fluorescence (absence of more than traces of sulphate of quinine or of quinidine). If sulphuric acid be added to a small quantity of the salt, not more than a faintly yellowish color should be developed (limit of readily carbonizable organic impurities). Upon adding to this solution a crystal of potassium dichromate the liquid should become yellowish green, gradually changing to grass green in color. If 1 Gm. be dried at 100 C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.92 Gm. (absence of an undue amount of water). If 0.5 Gm. of the salt be digested with 20 Cc. of cold distilled water, 0.5 Gm. of potassium sodium tartrate added, the mixture macerated, with frequent agitation, for 1 hour at 15° C. (59° F.), then filtered, and a drop of ammonia-water added to the filtrate, not more than a slight turbidity should appear (absence of more than small proportions of sulphates of cinchonine or quinidine).—U. S.

Action and Uses.—This alkaloid may be employed as a substitute for quinine. It is only about one-third as strong as quinine in its medicinal influences, and therefore, to be efficacious in malarial fever, much larger doses of it are required. The only advantage that it possesses over quinine is the claim made for it by some practitioners that it is less apt to produce fulness in the head and the other characteristic symptoms of the full physiological action of the more active alkaloid. Perhaps this lessened cerebral effect depends more upon the size of its dose and its inherent feebleness than upon any true variation in the susceptibility of the patient to the influence of these two alkaloids of cinchona. The dose is from 10 to 20 grains (0.60–2 Gm.).

CINCHONINA.—Cinchonine.

Cinchoninum.—Cinchonine, Fr.; *Cinchonin*, G.; *Cinconina*, It., Sp.

Formula, $C_{19}H_{22}N_2O$. Molecular weight, 292.03.

An alkaloid prepared from the bark of different species of cinchona. It was discovered by Pelletier and Caventou in 1820, and has been found in the largest proportions in some of the pale cinchonas.

Preparation.—Cinchonine is obtained commercially as a by-product in the manufacture of quinine after quinidine and cinchonidine have been removed from the mother-liquor, by precipitation with sodium hydroxide. The washed resinous precipitate is dissolved in dilute sulphuric acid and the sulphate purified by repeated crystallization. It is readily prepared by precipitating the aqueous solution of cinchonine sulphate with ammonia water, washing with water until free from ammonium sulphate, and crystallizing from alcohol.

Properties.—Cinchonine occurs as anhydrous, transparent white, somewhat lustrous prisms or needles, permanent in the air, odorless, at first nearly tasteless, but developing a bitter after-taste, and having an alkaline reaction; soluble in 3760 of water, and in 116 parts of alcohol at 15° C. (59° F.), in 3500 parts of boiling water, in 26.5 parts of boiling alcohol, 526 parts of ether, 163 parts of chloroform, and readily soluble in diluted acids, forming salts having a very bitter taste. At 240° C. (464° F.) the crystals fuse together, and at 258° C. (496.4° F.) they melt, forming a brown liquid. On ignition, the alkaloid is dissipated without residue.

Cinchonine is insoluble in solutions of ammonia and potassa, but dissolves in 108 parts of amyl alcohol, in warm fixed oils, volatile oils, benzene, and benzin. Its solutions are dextrogyrate; its acid solutions are not fluorescent, and do not give the thalleioquin reaction, but with chlorine-water and ammonia yield a white precipitate. Its alcoholic solution gives a yellow precipitate with picric acid which is insoluble in acids. The aqueous solutions of its salts are not precipitated by bicarbonates in the presence of tartaric acid, but yield precipitates with ammonia and other alkalies, their carbonates, with tannin, potassio-mercuric iodide, gold chloride, platinum chloride, phosphomolybdic acid, picric acid, and other reagents for alkaloids; also, by potassium ferrocyanide (Dollfus, 1848). This last reaction is to be applied in the following manner: If enough solution of potassium ferrocyanide be added to a neutral or not more than faintly acid solution of cinchonine, or any of its salts, to redissolve the precipitate first formed, and afterward an acid, a golden-yellow precipitate will occur, which

when slightly warmed will dissolve in the liquid, and on cooling separate in minute scales or needles.

By the action of potassa on cinchonine, Gerhardt (1842) obtained quinoline, and Greville Williams (1855, 1864) showed that in addition to this base the distillate also contained lepidine, cryptidine, and other bases. By long-continued boiling of its chloride with alcohol and potassa, König (1881) produced from cinchonine a crystallizable volatile base, *cinchene*, $C_{19}H_{20}N_2$. Michael (1886) obtained an oily, non-volatile base, $C_{20}H_{26}N_2$, by exposing sodium hydroxide, cinchonine, and absolute alcohol to a temperature of 130° C. (266° F.) in a closed tube. On oxidizing cinchonine or its salts by the action of lead dioxide and sulphuric acid, E. Marchand (1844) obtained *cinchotenine*, which is more readily obtained, according to Caventou and Willm, by the action of potassium permanganate, formic acid being formed at the same time. Cinchotenine, $C_{18}H_{20}N_2O_3$, by the further action of oxidizing agents yields Weidel's (1874) *cinchonic* (quinoline-carbonic acid), $C_{10}H_7NO_2$, *cinchomeronic*, $C_7H_5NO_4$, and other acids.

By the prolonged action of 50 per cent. sulphuric acid upon cinchonine at 120° C. (248° F.), Jungfleisch and Léger (*Compt.-rend.*, cxix. 1268) obtained *β-oxycinchonine*, $C_{38}H_{22}N_2O_4$, a strong base soluble in alcohol and dextrogyre. Cinchonine is an isomer of cinchonidine. By the action of sulphuric and hydrochloric acids, O. Hesse obtained 10 of the theoretically possible isomers of cinchonine (*Annalen*, 276, 88–124). Of these, *a-isocinchonine* ($S_d = +51.6$) is identical with the isocinchonine of Comstock and König and Jungfleisch and Léger's cinchoniline. *Benzoyl cinchonine*, a strong base forming neutral salts, was obtained by Léger (*Jour. Phar. Chim.*, 1893, 405) by heating cinchonine with benzoyl chloride.

Commercial cinchonine is frequently contaminated with a very similar alkaloid, which is not affected by cold potassium permanganate, is freely soluble in alcohol, yields a sulphate crystallizing in sharp needles, and is freed from cinchonine by fractional precipitation; Skraup proposed to call it *cinchotine*, and found it to be identical with Caventou and Willm's *hydrocinchonine*, $C_{19}H_{24}N_2O$.

Tests.—A solution of the alkaloid (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of quinine or quinidine). On precipitating the alkaloid from this solution by water of ammonia it is very sparingly dissolved by the latter (difference from and absence of quinine), and requires at least 300 parts of ether for solution (difference from quinine, quinidine, and cinchonidine). It should not be colored, or but very slightly colored, by the addition of sulphuric acid (absence of readily carbonizable, organic impurities).

Action and Uses.—As a remedy this alkaloid differs in no particular from quinine except that it is about one-third weaker. In large overdose, however, it is a convulsive, producing contractions, followed by exhaustion, and exciting præcordial pain and oppression. Its effect upon the nervous system is less marked than that of quinine, as it rarely produces vertigo, tinnitus aurium, or visual disturbances. As a tonic it may be given in doses of 1 or 2 grains (0.06–0.12 Gm.) several times daily. As an antiperiodic the dose is from 15 to 30 grains (1–2 Gm.), to be given as is quinine, in relation to the paroxysm.

CINCHONINÆ SULPHAS, *U. S.*—Cinchonine Sulphate.

Cinchoniæ sulphas, Cinchoninum sulfuricum.—Sulfate de cinchonine, Fr.; *Schwefelsaures Cinchonin, Cinchoninsulfat*, G.; *Solfato di cinconina*, It., Sp.

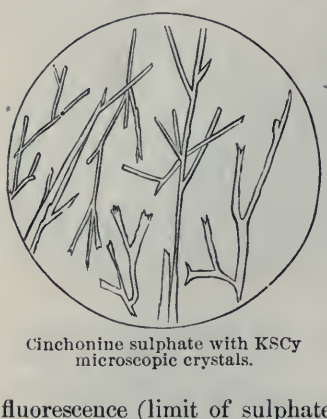
Formula, $(C_{19}H_{22}N_2O)_2H_2SO_4 + 2H_2O$. Molecular weight, 717.17.

Preparation.—Cinchonine sulphate is prepared from cinchonine by dissolving the alkaloid in the proper equivalent of dilute sulphuric acid. Neutralize 10 parts of cinchonine in about 200 parts of water with 10 parts of sulphuric acid, specific gravity 1.112, applying a gentle heat to hasten the combination. The solution is filtered while hot and the cinchonine sulphate obtained in crystallized form on cooling. If crystallized from water it will contain 2 molecules, and if from alcohol, 1 molecule, of water of crystallization.

Properties.—Cinchonine sulphate crystallizes in the form of colorless, transparent or white, lustrous, odorless, hard, clinorhombic prisms, which are permanent in the air, lose their water of crystallization (4.98 per cent.) at 100° C. (212° F.), and when heated to 198.5° C. (389.5° F.) fuse to a liquid and gradually decompose, forming a reddish

colored liquid, which at a higher temperature may be burned without residue. Cinchonine sulphate is soluble at 25° C. (77° F.) in 58 parts of water, 10 parts of alcohol, 69 parts of chloroform or 2300 parts of ether; at 80° C. (176° F.) in 32 parts of water, and at 60° C. (140° F.) in 5.2 parts of alcohol (U. S.). It is also soluble at 15° C. (59° F.) in 66 parts of water, in 13.5 parts of boiling water, and in 3.25 parts of boiling alcohol. Its aqueous solutions are neutral to litmus-paper, non-fluorescent, have an intensely bitter taste, and are strongly dextrorotatory. Its aqueous solutions are precipitated by the general alkaloidal reagents; by barium chloride (sulphate); by ammonium hydroxide, the precipitate being but sparingly soluble in excess of the reagent and suitable for the quantitative estimation of the alkaloid. When a drop of a saturated aqueous solution of the salt is mixed with a drop of solution of potassium sulphocyanate, crystals will be formed, which under the microscope will appear long, radiating, and considerably branched, resembling antlers or equisetum. Cinchonine sulphate contains 82.8 per cent. of cinchonine. By repeated crystallization of some of the commercial cinchonine sulphate, Skraup obtained *cinchotine*, $C_{19}H_{24}N_2O$, an alkaloid very similar to cinchonine, and identical with Caventou's and Willm's (1869) *hydrocinchonine*. It is more freely soluble in alcohol than cinchonine, yields a sulphate crystallizing in sharp needles, and is not affected by a cold solution of potassium permanganate.

Fig. 121.



Cinchonine sulphate with KSCy microscopic crystals.

Tests.—A solution of the salt (1 in 1000) in diluted sulphuric acid should not show more than a faint blue fluorescence (limit of sulphate of quinine or of quinidine). If 1 Gm. be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.95 Gm. If 1 part of the salt, reduced to powder, is macerated, with frequent agitation, with 80 parts of chloroform at ordinary temperature, it should wholly, or almost wholly, dissolve (limit of sulphate of quinine or cinchonidine). The salt should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of readily carbonizable organic impurities).—U. S.

Mixed with pulverized sodium chloride and heated on platinum-foil, purple fumes are developed.

Action and Uses.—Cinchonine sulphate may be employed in place of quinine in the treatment of malarial fever, and as a bitter tonic. It has no advantages over the more powerful alkaloid, and is very rarely used. It is about one-third as strong as quinine. The dose is the same as of cinchonine.

Other Salts of Cinchonine.—Cinchoninæ Sulphas Acidus. *Acid cinchonine sulphate, Cinchonine bisulphate.* $C_{19}H_{22}N_2O.H_2SO_4.3H_2O$. Molecular weight, 443.02.—Obtained by dissolving the official sulphate in dilute sulphuric acid and crystallizing; forms octahedral crystals, which become opaque in dry air, and dissolve in about half their weight of water and in 90 parts of alcohol. They are insoluble in ether, and contain 59.2 per cent. of cinchonine.

Cinchoninæ Hydrochloridum. *Cinchonine hydrochloride.* $C_{19}H_{22}N_2O.HCl.2H_2O$. Molecular weight, 363.97.—Made by treating an excess of cinchonine with dilute hydrochloric acid; crystallizes in needles closely resembling sulphate of quinine, dissolves in 24 parts of water at 10° C. (50° F.), in 3.2 parts of boiling water, in 22.2 parts of chloroform, in 1.3 parts of 80 per cent. alcohol, and in 273 parts of ether specific gravity 0.730 at 15° C. (59° F.). The salt melts above 130° C. (266° F.). It has been occasionally used for adulterating, or fraudulently sold for, quinine sulphate, from which it is readily distinguished by the absence of fluorescence of its acidulated solution, by the white precipitate occasioned with silver nitrate, and by the sparing solubility in ether of the white precipitate with ammonia. It contains 80.24 per cent. of cinchonine.

Cinchoninæ Iodosulphas. *Cinchonine iodosulphate, Antiseptol*, E.; *Cinchonin Herapathit*, G.—Antiseptol is prepared by adding a solution of 10 Gm. of iodine and 10 Gm. of potassium iodide in 1000 Cc. of water to a solution of 25 Gm. of cinchonine sulphate in 2000 Cc. of water. The precipitate is washed with water until the washings are free from iodine. The compound is somewhat variable in composition, but usually contains about 50 per cent. of iodine, and has been recommended by Yvon as a substitute for iodoform. It is a light-reddish-brown powder, insoluble in water, but soluble in alcohol and chloroform.

CINNALDEHYDUM, *U. S.*—Cinnamic Aldehyde.

Aldehydum cinnamicum.—Phenylacrolein, E.; *Aldéhyde cinnamique*, Fr.; *Zimmtaldehyd, Zimmtsäurealdehyd*, G.

Formula, C_9H_8O or $C_6H_5.CH:CH.COH$. Molecular weight, 131.07.

An aldehyde obtained from oil of cinnamon or prepared synthetically, containing not less than 95 per cent. of pure cinnamic aldehyde. It should be kept in small amber-colored, well-stoppered bottles.—U. S.

Preparation.—The natural product is obtained by shaking oil of cassia with an excess of concentrated aqueous solution of acid sodium sulphite, sodium cinnamal-hydroxy-sulphonate, $C_6H_5CH:CHCH(OH)SO_3Na$, being first formed, which latter is soluble and combines with a second molecule of the acid sulphite to form the sparingly soluble compound $C_6H_5CHSO_3Na.CH_2.CH(OH)SO_3Na.2H_2O$. The crystalline magma is separated by filtration, washed with cold alcohol, and decomposed with dilute sulphuric acid, cinnamic aldehyde being regenerated. Being but sparingly soluble in water the final product is readily separated from the aqueous liquid, and may then be rectified by distillation under reduced pressure.

Synthetically cinnamic aldehyde may be obtained by careful oxidation of cinnamyl alcohol, by dry distillation of a mixture of calcium cinnamate and formate, or as a condensation-product by acting on a mixture of benzaldehyde and acetaldehyde with hydrochloric acid gas. In place of the latter reaction a mixture of 10 parts of benzaldehyde, 15 parts of acetaldehyde, and 10 parts of 10 per cent. sodium hydroxide solution may be diluted with 900 parts of water and set aside for several days, when the two aldehydes will condense to form cinnamic aldehyde with elimination of water, as follows: $C_6H_5COH + CH_3COH = H_2O + C_6H_5.CH:CH.COH$.

Properties and Tests.—Cinnamic aldehyde is a colorless liquid having a cinnamon-like odor and a burning, aromatic taste. It boils at about 250° C. (482° F.) with partial decomposition. Its specific gravity is about 1.047 at 25° C. (77° F.) (at 15° C. (59° F.) 1.054–1.056, Swed. Pharm.). It is optically inactive. When the temperature is reduced by a freezing mixture, cinnamic aldehyde should solidify, and should melt again at —7.5° C. (18.5° F.). It is sparingly soluble in water, but soluble in all proportions in alcohol, ether, and fixed and volatile oils. If a small strip of filter-paper be folded in the form of a taper, saturated with cinnamic aldehyde, placed in a small porcelain dish and the latter in a larger dish, and if a clean beaker, moistened on the inner surface with distilled water, be inverted over the smaller dish, after igniting the taper, a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon addition of a few drops of silver nitrate test-solution (absence of chlorinated products).—U. S. The Swedish Pharmacopœia requires that an alcoholic solution of cinnamic aldehyde (1 in 50) should not be changed by addition of 1 drop of ferric chloride test-solution; also that a yellow crystalline nitro compound shall result when an equal number of drops of cinnamic aldehyde and fuming nitric acid are mixed in the cold.

Assay of Cinnamic Aldehyde.—Introduce into a counterpoised 150-Cc. flask, by means of a pipette, 12 drops of cinnamic aldehyde, and note the exact weight; add 5 Cc. of distilled water and a few drops of phenolphthalein test-solution, and then neutralize the solution exactly by the cautious addition of tenth-normal sodium hydroxide solution. Add 50 Cc. of a solution of sodium sulphite (1 in 5), and immerse the flask in a water-bath containing boiling water. From a burette add just sufficient half-normal hydrochloric acid to maintain the neutrality of the mixture, keeping the flask continuously heated and frequently agitated, and adding a drop or two of phenolphthalein test-solution. When a permanent condition of neutrality is reached, note the number of cubic centimetres of the half-normal hydrochloric acid consumed. Carry out a blank test identical with the foregoing, except that the cinnamic aldehyde is omitted, and note the amount of half-normal hydrochloric acid consumed.

Subtract the number of cubic centimetres required in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.033 Gm. of cinnamic aldehyde. To find the percentage, multiply the above difference by 0.033 and the product by 100, and divide by the weight of the cinnamic aldehyde taken.—U. S.

Rosolic acid test-solution is better suited as an indicator for this test than phenolphthalein.

Action and Uses.—Cinnamic aldehyde is the active medicinal ingredient of oil of cinnamon, and may be employed for the same purposes as the latter drug. (See OLEUM CINNAMOMI.)

CINNAMOMUM, *U. S., Br., P. G., Fr., It.*—Cinnamon.

Canelle, Fr.; *Zimmt*, G.; *Canella*, It., Sp.

The bark of several species of *Cinnamomum* Blume (Fam. *Lauraceæ*), as follows:

(1) CINNAMOMUM CASSIA, P. G.—*Cortex cinnamomi chinensis, Cortex cinnamomi cassiæ, Cinnamomum chinense, C. Indicum, Cassia cinnamomea.—Cassia cinnamon, Chinese cinnamon, Cassia bark, Cassia lignea, Cassia vera*, E.; *Zimmtkassie, Chinesischer (Gemeiner) Zimmt*, G.; *Canelle de chine*, Fr.; *Canella*, It., Sp.—The dried bark of the shoots of *C. Cassia* (Nees) Blume (*Laurus C.* Nees; *C. aromaticum* Nees) deprived of most of its corky portion.

(2) CINNAMOMUM SAIGONICUM, U. S.—*Saigon cinnamon, Annam cinnamon, China cinnamon, God's cinnamon*, E.; *Saigonzimmt*, G.; *cannelle de Saigon*, Fr.—The dried bark of an undetermined species of *Cinnamomum*.

(3) CINNAMOMUM ZEYLANICUM, U. S.—*Cinnamomi Cortex*, Br.; *Cortex cinnamomi zeylanici, Cinnamomum acutum, C. verum.—Ceylon cinnamon, Cinnamon bark*, E.; *Zeylonzimmt*, G.; *Canelle de Ceylon*, Fr.; *Canella del Ceylon*, It.—The dried inner bark of the shoots of *C. Zeylanicum* Breyne.

Cinnamon is official in all pharmacopœias, though they differ much as to the varieties recognized. The Br. P. recognizes only the Ceylon bark.

Origin.—The genus *Cinnamomum* is credited with upward of 50 species, of tropical Asia, including the East India islands, but relatively few of them yield cinnamon. *C. Zeylanicum*, the best known, is native of Ceylon and perhaps of adjacent regions, but the present bark of commerce is almost all the product of cultivated plants. If allowed to grow, it forms a small evergreen tree, but it is pollarded so as to form a dense mass of slender straight branches. These are cut off when about 2 years of age and 1 or 2 inches in diameter, and before the astringent corky layer has a chance to form. The bark is removed in quills or strips, and after being allowed to wilt for a day, so as to become soft and pliable, is laid with the inner surface down and scraped off to the layer of stone-cells, the outer bitter or astringent portion being thus rejected. Care is taken not to use iron tools, as they cause blackening of the bark. A number of the strips are then peeled and rolled together to form the compound quills of commerce, and are carefully dried, for a day in the shade and afterward in the sun. They are marketed in large cylindrical bundles resembling rolls of carpet in size and form.

Saigon cinnamon appears to be derived wholly from wild trees, growing over a very limited area of mountainous territory in Annam. The entire bark of the trees, which are reported as being sometimes several feet in circumference and up to 200 years of age, is taken, though most of the bark which reaches us is from branches or stems apparently of less than the thickness of a man's arm. This sort is highly prized by the Chinese, who, with their usual superstition, attribute magical powers to certain pieces, for which fabulous prices are charged. It is cut into quills about a foot in length and dried entire, then tied in cylindrical bundles nearly a foot in diameter, each bundle representing quills of one of three sizes, the medium size (Fig. 123) being first in quality. It sometimes comes in chips of thick trunk-bark; the whole of it, if of good quality, even to the outermost cork, being sweet, aromatic, and nearly free from bitterness and astringency. The botanical origin of this bark has been much discussed. British writers have persistently connected it with cassia bark, and Pfister has distinctly stated that it is "unscraped cassia," but we must utterly reject this view. *C. Cassia*, being cultivated, is well known. Its cork is removed because of its highly objectionable qualities, from which that of the Saigon variety is commonly free. The Saigon pertains to a distinct floral area, and, unless we arbitrarily apply to it the name of cassia, as Pfister has done, its structure is distinct from that of cassia. There appears little doubt that it represents a less excellent grade of that distinctively Chinese cinnamon which is so highly prized by the Chinese, and which represents a species, perhaps several, distinct from *C. Cassia* (Nees) Blume. Certainly, its quality is quite distinct from that of any known to come from *C. Cassia*, so that it is convenient and practical to hold it apart from cassia, while recognizing its relation to this, rather than to Ceylon cinnamon.

C. Cassia is cultivated in southern China for the better quality of the cassia bark of commerce. The stems are allowed to reach the age of 5 or 6 years before being cut. The bark is removed in pieces about 16 inches in length and representing half the circumference of the stem. These strips, after wilting, are laid face down and the outer

layers imperfectly removed by planing. It is then tied into bundles for exportation. There is a form cultivated in Java, and known as *Batavian cassia*, from which the outer bark is scraped, of light color and excellent flavor, which perhaps is not from this species. The limitations of the above view obviously exclude a large part of the barks commonly known as Cassia. These will be considered under *Substitutes and Adulterants.*

FIG. 122.

Cinnamon.

FIG. 123.

Saigon cinnamon (Nat.).

Description.—CEYLON CINNAMON.—Long, closely rolled quills, each composed of 8 or more layers of bark of the thickness of paper; pale yellowish-brown, the outer surface smooth, marked with wavy lines of bast-bundles, the inner surface striate; fracture short-splintery; odor fragrant; taste sweetish, aromatic, faintly pungent, with little or no astringency.

Ceylon cinnamon exhibits the following structures, from without inward: (1) small scattered bast-fibers lying upon the surface of (2) a zone, mostly of 3 layers of stone-cells which are tangentially elongated, much and not very unequally thickened, and contain numerous pores; (3) some scattered sieve-tissue, with occasional bast-fibers in the cortical parenchyma; (4) bast-wedges alternating with medullary rays. In this bast-parenchyma are very large oil- and mucilage-cells; also, in both the medullary rays and bast-parenchyma, especially the former, cells containing acicular raphides, and large quantities of starch in very small grains. The bast-fibers taper acutely to both ends. Pfister names as the characteristics of this variety the relatively large number of bast-fibers, the markedly tangential elongation of the stone-cells, the isodiametric cells of the secondary parenchyma, and the acicular raphides, especially abundant in the medullary ray-cells. Tschirch has demonstrated the intimate relations, as to derivation, between the oil and the mucilage, and indicates the probability that the former is produced, at least in part, at the expense of the latter.

SAIGON CINNAMON.—In quills or quilled strips about 25 to 30 Cm. (10 to 12 In.) long and mostly from 0.8 to 2.5 Cm. ($\frac{1}{3}$ to 1 In.) in diameter, the bark 1 to 6 Mm. ($\frac{1}{25}$ to $\frac{1}{4}$ In.) thick; outer surface of the thinnest bark deep-brown or red-brown, of the thicker, gray or brownish-gray, with or without lighter patches, and more or less rough from scale-like warts, fine longitudinal wrinkles and, except in the thinner quills, some transverse ridges; inner surface cinnamon-brown to dark or reddish-brown, finely granular and very finely and indistinctly striate; fracture short, granular, exhibiting an almost continuous whitish middle layer between two brown ones, the outer indistinct in thick barks; odor fragrant; taste sweet, aromatic and pungent, with very little or no astringency.

Structurally, this is distinguished from the preceding by the presence of a periderm overlying the zone of stone-cells, the latter being nearly isodiametric, the starch-grains about a half larger. In the powder, the dark color, the great abundance of cork-cells, and the small number of bast-fibers as compared with the Ceylon variety, the isodiametric stone-cells, and larger starch-grains, furnish a ready means of distinction.

Cassia Cinnamon.—In quills of variable length and 0.5 to 2 Cm. ($\frac{1}{5}$ to $\frac{4}{5}$ In.) in diameter, the bark 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ In.) thick; yellowish-brown, the outer surface often marked with grayish patches, which are more or less warty- or scaly-roughened, the inner nearly smooth, faintly striate; fracture nearly smooth, exhibiting an interrupted middle whitish layer between two reddish-brown ones, the outer of these usually nearly or quite wanting; odor somewhat fragrant; taste sweetish, aromatic, more or less pungent and astringent.

The structure of cassia may be distinguished by the varying presence or partial or entire absence of the cork-tissue; as compared with the Ceylon or Saigon, by the wider but much more irregular zone of stone-cells, the greater abundance of bast-fibers and of tannin masses. In the powder, the abundance of stone-cells and bast-fibers and tannin-cells, and the medium percentage of cork-cells are characteristic.

Constituents.—All the cinnamons contain volatile oil, mucilage, resin, tannin, mannite, and bitter substance, in varying relative proportions. In typical samples, the Saigon variety contains the most volatile oil (1 per cent. or more) and mannite, the cassia variety coming next, and the Ceylon last, the oil of the last ranging from 0.5 to nearly 1 per cent. Cassia contains the most and Saigon the least, of both tannin and bitter substance. The percentage of mucilage is apt to vary inversely with that of the oil. The oil of cinnamon (see Oleum Cinnamomi) is not identical in the different barks, that of Ceylon cinnamon being generally recognized as of finer and more permanent flavor, while the Saigon, being sweeter, is more aromatic, but the aroma is less permanent. In a first-class Saigon bark, bitterness and astringency are scarcely appreciable. This is true also of the Ceylon bark as to bitterness, though more or less astringency is usual. The tannin in the Ceylon bark ranges from about 3 to 5 per cent. (*Thornton*). It is either a phlobaphene in the drug or acquires a phlobaphene character when brought into contact with water. It is very similar to the tannin of white oak bark, yet shows distinct reactions. The bitter constituent, sometimes present in appreciable amount in cassia, is unknown. The mannite has been called *cinnamanin*. Ceylon cinnamon yields up to about 3 per cent. of ash, cassia about 4 per cent.

Adulterants and Substitutes.—Those of the entire barks are first considered. Ceylon cinnamon, in the entire state, is scarcely capable of substitution.

Saigon cinnamon is sometimes substituted by cassia, and regularly by a bark closely resembling itself in appearance and slightly in taste, of unknown derivation. This is of a lighter gray and a coarser structure, and is at once identified by its very weak odor and taste. This may be the use made of the large unscraped Guava bark quills, which are said to be soaked in cinnamon water, dried, and the ends touched up with cinnamon oil. Only the greatest carelessness could admit of mistaking anything other than the best grades of cassia for Saigon cinnamon.

Cassia bark, as already indicated, is subject to the most extensive and varied substitution; or, this might be differently stated by saying that commercial cassia bark is of very varied origin, with the result of a corresponding variation in quality. To so great an extent is this true that even in the better drug trade there are more or less regularly different interpretations of the term "cassia," "cassia vera," "cassia lignea," etc., in different countries, depending upon different commercial relations. Pfister states that Sumatra cassia (*C. vera Padang*), as well as a portion of that of Java and perhaps of China, that of Timor and the red-brown Vogl sort, is from *C. Burmanni* (agreeing in structure with those from *C. dulce* Nees and *C. Kianus* Nees); that some from Calcutta, grown in northern India, as well as some from Cochin China, is from *C. Tamala* (the same as *C. albiflorum* Nees); and that part of that from the East Indian archipelago is from *C. iners*. He also states that the bark called *Cassia vera* in England is the *C. lignea* of the Continent (from *C. Burmanni* and *C. Tamala*), while these applications of the names are exactly reversed as to the product of *C. Cassia*, the American *Saigon cinnamon* going as *China cinnamon* in London. Pfister has also published the following structural characteristics of these unofficial barks: *C. obtusifolium* has acicular raphides, numerous bast-fibers, and the stone-cells tangentially elongated, as are the secondary parenchymatic cells. The last is the only particular in which it differs from Ceylon cin-

namon. *C. iners* differs from both the last only in having its stone-cells radially elongated. *C. Loureiri*, *C. Burmanni*, and *C. Tamala* have the raphides tabular, the first-named with porous thickening of the medullary ray-cells, the others little if at all so, and *C. Tamala* having porous thickening of its secondary parenchymatic cells, *C. Burmanni* not. *C. Sintok* has well-defined zones of stone-cells in the secondary bast; *C. Culilawan* (probably the so-called *Mountain cinnamon*), with a clove-like odor, has them in numerous groups. *Massoi bark*, with the odor and taste of cocoanut oil, from an unknown species, has the stone-cells containing raphides singly or in pairs, while false Massoi bark has the clove-like odor of Culiliwan bark.

Aside from these differences in the origin of cassia, it is subject to other adulteration. The common Chinese mats are packed with good, perfect quills upon the outside and broken and poor pieces within, and a small handful of sand thrown into each.

Commercial powdered cinnamon of all kinds is rarely, if ever, strictly pure. As to the Ceylon variety, there is scarcely a pretence of supplying it as a ground cinnamon. In 1894 the Division of Chemistry, U. S. Department of Agriculture (*Bulletin No. 13*, p. 2), published the statement that "not a particle of ground cinnamon" (referring to Ceylon cinnamon) "can be found upon the market." "Not a particle of material labelled ground cinnamon proved to be anything other than cassia."

Besides this use of cassia, cinnamon and cassia chips (see *Allied Products*) and the siftings are regularly ground for cinnamon. Its wood-fibers and vessels are clearly visible. The weak odor and taste thus produced are then strengthened by adding cassia buds, which add to the powder small conical thick-walled hairs, long thick-walled cells, and spiral vessels much smaller than those of the wood. Walnut shells are said to be used for the same purpose, and are readily detected by their well-known stone-cells. It goes without saying that many ordinary vegetable tissues, as those of beans and grains, have been used. They are recognizable by the character of their starch-grains.

Pharmaceutical Preparations.—Syrup of Cinnamon, N. F.; Tincture of Cinnamon, U. S. P.

Action and Uses.—Cinnamon is employed as an aromatic, carminative, hæmostatic, and intestinal stimulant. Both the oil and the drug itself are useful remedies in the treatment of nausea and vomiting, flatulent colic, and serous diarrhœa. The oil is especially useful as a hæmostatic, and when given internally lends itself in the control of passive uterine hemorrhages. It has also been recommended by J. Chalmers Da Costa, in the proportion of from 1 to 3 minims (0.05–0.20 Cc.) of the oil to 1 fluidounce (30 Cc.) of benzoinol, as an injection for the early stages of gonorrhœa. Cinnamic acid may be given for all of the above conditions, but it has been especially recommended as a palliative for the cough of tuberculosis. For this purpose it is injected hypodermically deep into the muscular structures. The beginning dose is 2 minims (0.10 Cc.), which may be gradually increased to 15 minims (1 Cc.). Its injection, however, is quite painful, and for this reason the employment of the drug has never been largely practised. The dose of powdered cinnamon is from 10 to 20 grains (0.60–1.3 Gm.), and of the oil from 1 to 5 minims (0.06–0.3 Cc.).

Allied Products.—Cassia Buds (*Flores cassiæ*, *Clavelli Cinnamomi*) are the small, stem-like, immature fruits of various species. They bear some resemblance to cloves, but are smaller and the structure less prominent. They consist of the thick perigone, its 6 small lobes folded over the depressed ovary. The best of these have a powerful and fine cinnamon odor and taste, and they contain oil of cinnamon and tannin in exceedingly variable proportions in different lots. *Cinnamon leaves* also enjoy a very considerable trade. Under the name of *Tej pat*, the Sanskrit equivalent of cinnamon leaf, those of *C. Tamala*, native and abundant in the Himalayas, are very largely dealt in as a condiment and aromatic medicine in Assam, where they are also produced by cultivation. It is said that a portion of the product is derived from other species, *C. albiflorum* Nees, *C. obtusifolium* Nees, *C. impressinervium* Nees, and wild plants of *C. Zeylanicum* being so named. The odor of these leaves has been compared to that of a mixture of cloves and cinnamon. Their volatile oil, present in very variable amount, is mostly eugenol. They have also been used in India for dyeing.

Cassia Caryophyllata (*Cortex caryophyllatus*), or *Clove-bark* (*Nelkenzimmt*, G.), is from *Dicypellium caryophyllatam* Nees, of Brazil. It usually comes in quills 2 to 4 Cm. ($\frac{3}{4}$ to $1\frac{1}{2}$ In.) thick, and about 60 Cm. (2 Ft.) long, which are made up of about 6 to 10 pieces of bark rolled up together. The bark is about 1.5 M. ($\frac{1}{16}$ In.) thick, smooth or slightly wrinkled, chestnut-brown, often with a bluish tinge, fracture short, showing a whitish line near the outer margin; odor clove-like; taste mucilaginous, resembling cinnamon.

CISTACEÆ.—The Rock-rose Family.

A small and unimportant family of 4 genera and about 150 species, occurring mostly in Europe, and especially in the Mediterranean region. The most common constituent is tannin, usually associated with volatile oil, for which many species are used as astringents, tonics, and vulneraries, and some as emmenagogues, notably *Cistus Cyprinus* Lam., *C. Monspeliensis* L., and *C. salviæfolius* L. (*Berber* or *Burbur* of the Arabs), *Helianthemum vulgare* (L.) Gærtn. (*Cistus v.* L.), of Europe, and the American species *H. corymbosum* (L.) Mx. (*Cistus c.* L.) and *H. Canadense* (L.) Mx. (*Cistus C.* L.), the *Frostweed* or *Frost-wort*. All these plants are commonly known in their respective localities as *Rock roses* or *Roses*, though they are recognized as being in no way related to the true roses. The last-named species (*Canadian rock rose, Canadisches Sonnenröschen*) is considerably used and is an article of commerce. Its description is as follows: stem slender, rigid, about 25 to 35 Cm. (10 to 15 In.) long, pubescent; leaves alternate, varying from narrowly lanceolate to elliptical, entire, obtuse or acutish, hairy underneath, about 2.5 Cm. (1 In.) long; flowers of early summer solitary, stalked, 5-merous, with large yellow petals; those of later summer in axillary clusters, nearly sessile, small and without petals; stamens numerous, hypogynous; fruit a 3-valved, 1-celled capsule, shorter than the calyx and containing a few brown seeds. This drug contains about 10 per cent. of tannin, fat, a very small amount of volatile oil, and a white crystalline bitter substance, probably a glucoside. *Helianthemum canadense* is an aromatic bitter possessing astringent properties. It is not largely employed at the present time, but was formerly considered a useful alterative in the treatment of constitutional syphilis and scrofula. Because of its astringency it was administered as a useful remedy in diarrhœa, and in the form of a gargle was employed in the sore throat occurring in scarlatina. A wash prepared from the plant has also been used locally in the treatment of prurigo. Internally, the extract is commonly employed in the dose of from ½ to 2 grains (0.03–0.13 Gm.), but the latter amount sometimes produces vomiting.

Probably the most important product of the family is the peculiar resinous substance, *labdanum* or *ladanum* (E., G., Fr., Sp.), which is obtained in the Mediterranean region as an exudation from *Cistus Creticus* L., *C. Ladaniferus* L., and other species of *Cistus*. The substance is gathered either by whipping the plants with leather thongs, to which it adheres, or by collecting it from the wool of sheep which have been made to travel among the plants. It occurs either in dark-brown or blackish masses, gray upon fresh fracture, or in cylindrical rolls like stick licorice or in flat pieces. The heat of the hand is sufficient to soften and make it glutinous. It is insoluble in water, almost completely soluble in alcohol, fusible, burns with a bright flame, and has a pleasant balsamic odor and a bitter taste. Being a distinctly expensive article, it has been much subjected to adulteration. Guibourt found it to consist of 86 per cent. of resin and volatile oil, 7 per cent. of wax, 1 per cent. of extractive matter, and 6 per cent. of insoluble impurities. Pelletier found a sample to contain 72 per cent. of sand, with only 20 per cent. of resin. Labdanum, on account of its aromatic properties, is occasionally employed as an ingredient of plasters, but it is no longer given in internal medicine. Formerly it was employed internally and by fumigation in the treatment of chronic bronchitis. Its internal administration was also considered useful in dysentery and dropsy.

COCA, *U. S.*—Coca.

Erythroxylon, U. S. P. 1880; *Cocæ Folia*, Br.; *Coca leaves*, E.; *Cocablätter*, G.; *Feuilles de coca*, Fr.; *Ipadu*, Sp.; *Ypadu*, Port.; *Cuca, Acullico*, Peruv.

The dried leaves of *Erythroxylon Coca* Lamarck (Fam. *Erythroxylaceæ*), known commercially as Huanuco Coca, or of *E. Truxillense* Rusby, known commercially as Truxillo Coca, yielding, when assayed by the process given below, not less than 0.5 per cent. of the ether-soluble alkaloids of coca.

Origin.—The coca plants are large cultivated shrubs of the eastern Andes, now introduced to some extent into other parts of tropical South America, Central America, Mexico, and the West and East Indies, though relatively little of the commercial product originates outside of Peru, Bolivia, and Ecuador. Neither of the species is known in a wild state in the same form as that of cultivation, except as a recent escape. The *E. Coca*, at least, after such escape, quickly begins to undergo marked changes in leaf-characters. It is very probable that both are forms developed by long cultivation, since prehistoric times, from wild species either now living under different forms or already extinct. The *E. Coca*, grown mostly in Bolivia and Southern Peru, thrives best and produces the best product at from 3500 to 6000 feet, in 18° south, and at elevations with a corresponding climate in other latitudes. It can be produced, and grows fairly well, at lower elevations, but the product is inferior. The relative quality, as here and elsewhere considered in this article, is that determined by the native chewers, using it for the systemic support that it affords, and mostly independent of the percentage of

crystallizable cocaine. The Truxillo variety, which is a more northern product, does well at lower elevations. The shrubs are usually cultivated on terraces of the steep slopes, and do best with a few shade-trees (usually of *Inga*) scattered through the plantations; but if grown in deep shade, they develop a bitter taste, as they also do when grown at very low elevations. They require a very humid atmosphere. There are minor differences in quality, both as to the native standard and the yield of cocaine, according to the character of season, soil, exposure, and other conditions. The leaves are picked by hand when fully grown, but before approaching closely to the condition of falling. A plant yields 2, sometimes 3, harvests in the year. Although April and September yield the principal crops, yet picking is not confined to any season, going on continuously upon different plantations. Sixty to eighty pounds per acre of dried leaves at a picking is a fair yield. The leaves are dried quickly, within 2 or 3 hours, in hot sunshine, and not the least moisture is allowed to reach them. After lying in a loose pile in the coca-house for 2 or 3 days, they are again briefly exposed to the sun, to dry off the perspiration which has developed, and are then powerfully compressed into small bales called "cestos," nominally of 25 pounds each, but almost invariably short in weight. Two cestos are then sewn into a rawhide, and when this has thoroughly dried are ready for transportation. The chief differences in quality of properly cured coca

leaves result from their relative freshness and the care exercised in keeping them. Proper drying makes practically no difference in the constituents, but immediately thereafter deterioration begins. Leaves which have been preserved for a few months are regarded as distinctly inferior, and long before a year they are regarded as unfit for use. Assay determines that there is also a gradual loss of cocaine on keeping them, greatly increased by dampness.

Description.—Huanuco Coca.—Greenish-brown to clear brown, smooth and slightly glossy, thickish and slightly coriaceous, stoutly and very shortly petioled, the blade 2.5 to 7.5 Cm. (1 to 3 In.) long and about half as broad, oval and nearly elliptical, with a very short, very abruptly narrowed basal portion and a very slight point, entire, the midrib traversed by a slight ridge above, very prominent underneath, the venation rather obscure, especially above; underneath, 2 conspicuous lines of collenchyma tissue run longitudinally upon either side of the midrib and at about one-third of the distance from it to the margin, the enclosed areola being of a slightly different color from the adjacent surface; odor characteristic; taste bitterish, faintly aromatic, and followed by a numbness of the tongue, lips, and fauces. Huanuco coca should yield not less than 0.5 per cent. of crystallizable cocaine.

Truxillo Coca.—Pale-green, thin, brittle, and usually much broken; smooth, not shining; shortly and stoutly petioled, the blade 1.6 to 5 Cm. ($\frac{2}{3}$ to 2 In.) long and one-third to one-half as broad, obovate to oblanceolate, narrowed from near the middle into the petiole, usually with a slight projecting point at the summit, entire; upon the lower surface 2

irregular lines of collenchyma tissue, frequently wanting and usually incomplete or obscure, run beside the midrib, their middle portions arching away to about one-third of the distance from the midrib to the margin ; odor characteristic, tea-like ; taste bitterish, faintly aromatic, followed by a numbness of the tongue, lips, and fauces. In our illustration of this variety, the lateral lines are more distinct than is usual.

The powder is characterized by the peculiar epidermal cells of the inferior surface, with their papillose-thickened outer walls. Efforts to distinguish the two varieties in the powdered form, except by the yellowish-green color of the Huanuco and the pale-green color of the other, have proved unsuccessful, though the papillæ of the Truxillo variety are usually higher than in the other.

Inferior leaves are generally to be recognized by their color, odor, and weaker anæsthetic effect upon the tongue, lips, and palate. One who is experienced can determine the cocaine percentage pretty closely by the latter test. As to color, the Huanuco variety, if of a bright-green, has usually been collected before maturity. A brownish-green or brown color is typical, but the brown should be clear and rich, and with a slight glossiness. A smudgy brown or a very dull surface indicates damage in curing or in transit, to which latter coca is very subject.

Adulterants and Substitutes.—Adulteration, in the strict sense of the term, is almost unknown in the case of entire coca leaves, and nothing can be mistaken for them, even upon casual examination. In a single instance, a considerable (40 to 50 per cent.) addition of small jaborandi leaves, evidently effected in Europe, was reported. Small quantities of Inga or Pacay flowers frequently occur, by accident. Among the natives, recourse has been had, in times of scarcity, to the leaflets of a native tree, under the name of *Chinchicoca*, but these have never been exported.

Constituents.—The constituent or constituents of native coca leaves, representing their physiological value to the coca-chewers, are entirely unknown, or, at least, this connection has never been established. It may be found, or indicated, by a physiological study of the secondary alkaloids referred to below. The important constituent of the Huanuco, and to a lesser extent of the Truxillo leaves, from our present therapeutic standpoint, is crystallizable cocaine (see COCAINA), of which there is from 0.4 to 0.8 per cent. in the Huanuco variety, and about a half or two-thirds as much in the Truxillo. It has been claimed that in some cases the latter yields as much as the former, but we doubt the identity of those leaves, unless other alkaloid has been converted into cocaine during manufacture. A Huanuco leaf of satisfactory quality will yield as much as 0.5 per cent. By careful assay, nearly twice this amount has been obtained. Besides the secondary alkaloids, there is cocatannic acid, giving a green color with iron salts, wax, and a very slight amount of volatile oil or similar aromatic principle. The secondary alkaloids are *cinnamyl-cocaine*, in which cinnamic acid takes the place of the benzoic acid of cocaine, and *truxilline*, in which the corresponding acid is *truxillic*. Both these, as well as cocaine, upon hydrolysis, yield methyl alcohol and *ecgonine*, which latter is therefore found to some extent in the leaves. Cinnamyl-cocaine ($C_{19}H_{23}NO_4$) occurs in needle-shaped crystals, which melt at 121° C. (249.8° F.). Truxilline (truxil-cocaine, isotropyl-cocaine, or cocamine—$C_{19}H_{23}NO_4$) occurs in large crystals, melts at about 120° C. (248° F.), and has been synthetically prepared from ecgonine and cinnamic anhydride. The truxillic acid which it yields appears to be a mixture, or the term is applied indefinitely to *cocaic*, *isococaic*, and *homo-isococaic acids*. Truxilline is much more abundant (sometimes 0.5 per cent.) in the Truxillo leaves, where it was first discovered. Ecgonine ($C_9H_{15}NO_3$—very similar to tropine) is soluble in water, slightly in alcohol, and insoluble in ether. It occurs in prismatic crystals, and is only slightly bitter. *Hygrine* has frequently been written of as an alkaloid, but its identity as a constituent of coca leaves is denied. It is by no means certain that this denial is well founded, and it is to be regarded as a doubtful substance. *Cocaimidine*, not yet thoroughly studied, is reported by Schaefer as being a distinct alkaloid, probably isomeric with cocaine, less anæsthetic, and yielding crystalline salts. There are strong reasons for believing that, connected with these marked differences in the composition of the two varieties of leaves, the Truxillo approaches more nearly to the physiological action of the native-chewed coca.

History.—The history of coca is most intimately entwined with the religious, social, and even political history of the people of Peru and the adjacent countries, and has even left its permanent impression upon that of their conquerors (see Mortimer's *Peru, The*

History of Coca). This history is of great physiological interest, since coca is unquestionably the agent which has enabled the dwellers of the higher Andes not only to withstand the effects of a high elevation, but to become noted for their physical strength and endurance in spite of them. Deprived of its support, those abilities fail. Foreigners going there have found it possible to gain a similar assistance from its use, and to endure without distress physical trials which are otherwise unendurable. The natives chew the leaves regularly several times during the day, the total daily amount being about ½ ounce, remaining perfectly inactive while the operation is in progress. The leaf is commonly chewed with *llipta*, a mixture the chief ingredient of which is ashes, those from certain plants being preferred. Aside from the effect of flavoring the mass, very much as salt would do, it is not improbable that the alkali of the ash brings about changes in the constituents, rendering them more active or more available to the system. A coca-habit may be said to be unknown among these people, who chew the leaf from youth to old age, without ill effects.

The U. S. P. requires that coca leaves shall contain not less than 0.5 per cent. of ether-soluble alkaloids when assayed by the following process:

Assay of Coca.—Coca, in No. 60 powder, 10 Gm.; chloroform, ether, normal sulphuric acid, ammonia-water, distilled water, tenth-normal sulphuric acid, fiftieth-normal potassium-hydroxide solution, hematoxylin or iodeosin test-solution, each a sufficient quantity. Place the coca in an Erlenmeyer flask, add 50 Cc. of a mixture of chloroform 1 volume and ether 4 volumes, and insert the stopper securely. Allow the flask to stand ten minutes, then add 2 Cc. of ammonia-water mixed with 3 Cc. of distilled water, and shake the flask well, at frequent intervals, during one hour. Then transfer as much as possible of the contents of the flask to a small percolator which has been provided with a pledget of cotton packed firmly in the neck, and insert in a separator containing 6 Cc. of normal sulphuric acid, diluted with 20 Cc. of distilled water. When the liquid has passed through the cotton, pack the coca firmly in the percolator with the aid of a glass rod, and, having rinsed the flask with 10 Cc. of chloroform-ether mixture, transfer the remaining contents of the flask to the percolator by the aid of several small portions (5 Cc.) of the chloroform-ether mixture, and continue the percolation with successive small portions of the same liquid (in all 50 Cc.). Next shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid liquid into another separator. Add to the chloroform-ether mixture 10 Cc. of the sulphuric-acid mixture, agitate well and again draw off the acid liquid. Repeat this operation once again, drawing off the acid solution as before into the second separator, collect the acid solutions in the second separator, and introduce a small piece of red litmus-paper; then add ammonia-water until the liquid is distinctly alkaline, and shake out successively with 3 portions of 20, 20, and 15 Cc. of ether. Collect the ether solution in a beaker, place it on a water-bath filled with warm water, and allow the ether to evaporate entirely. Dissolve the residue in 3 Cc. of ether, and let this also evaporate completely. To the alkaloidal residue add 4 Cc. of tenth-normal sulphuric acid and 5 drops of hematoxylin or iodeosin test-solution, then titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 4 (the 4 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.03, and this product by 10, to obtain the percentage of ether-soluble alkaloids contained in the coca.—U. S.

The Puckner-Gunn method for assaying coca gives very satisfactory results and is less troublesome than the former. Moisten 5 Gm. of the powdered drug with 3 Cc. of 2 per cent. ammonia water, and at once pack very firmly into a small cylindrical percolator. Shake 100 Cc. of ether with 5 Cc. of 28 per cent. ammonia water in a separator, draw off the watery portion, and percolate the drug slowly with the ammoniated ether directly into a separator containing 20 Cc. of 1 per cent. hydrochloric acid; finally pass a further portion of 20 Cc. of plain ether through the mark in the percolator. When all the ethereal menstruum has passed, the contents of the separator are well shaken, and after perfect separation the acid aqueous liquid is drawn off into another separator. The ethereal liquid is shaken twice more with separate portions of 10 Cc. of 1 per cent. hydrochloric acid, the latter being each time drawn off and added to the acid liquid in separator No. 2. The combined acid liquids are rendered just alkaline with ammonia water and shaken out 3 times, using 20, 15, and 10 Cc., with chloroform, which latter is carefully drawn off and allowed to evaporate on a warm, not boiling, water-bath. The residue, when dry, is treated with 5 Cc. of ether to remove adhering traces of chloroform, again dried, dissolved in 10 Cc. of decinormal acid, and titrated with centinormal alkali, using hæmatoxylin solution as an indicator. Divide the number of Cc. of alkali solution used by 10, subtract the quotient from 10, and multiply the remainder by 0.030 and then by 20, to get the percentage of cocaine present in the sample.

Pharmaceutical Preparations.—Aromatic Wine of Coca, N. F.; Elixir of Coca, N. F.; Elixir of Coca and Guarana, N. F.; Fluidextract of Coca, U. S. P.; Wine of Coca, N. F.

Action and Uses.—The action of coca upon the inhabitants of its native country is markedly different from that of its alkaloid *cocaine* upon those residing in North America and European countries. The Indians of Peru and Bolivia employ an infusion of the leaves as a stomachic, stimulant, and mild diaphoretic. The leaves mixed with ashes or lime are also chewed for the purpose of allaying hunger, appeasing thirst, preventing fatigue, and overcoming mental depression. It has been generally stated that this habit produces utter mental and physical degradation in these persons, but Rusby failed to find any such cases, although for more than a year he was associated with coca-chewers and made diligent inquiry concerning them in general and these results in particular. The moderate use of coca leaves is, therefore, apparently productive of no such untoward effects in these Indians. Taken in moderate amounts coca or cocaine produces a sense of exhilaration.

The application of cocaine to mucous membranes causes first a blanching and then local anæsthesia by its depressing effect on the peripheral nerves of sensation. When given internally, cocaine stimulates the central nervous system, but, unless the dose be poisonous, has little effect upon the sensory nerves. The drug in moderate doses stimulates the cerebrum, increasing the rapidity of thought, and acts as a stimulant to the medulla, increasing the number of respirations and elevating blood-pressure. If the dose be a poisonous one, the drug acts as a depressant, lowering blood-pressure, producing irregular and shallow respirations, and at times causing tonic and clonic convulsions of cerebral origin. Under its administration the heart's action becomes more rapid and forcible, a condition which is probably due either to a direct stimulation of the heart muscle or its accelerator nerves. In moderate amounts it has no effect upon the temperature, but overdoses cause a rise of several degrees by increasing heat-production. Cocaine is principally destroyed in the body, but a portion is eliminated by the kidneys. The urine is usually augmented during its administration, but the nitrogenous elements are slightly decreased.

The chief use of cocaine in medicine is as a local anæsthetic. When introduced into the eye, cocaine produces mydriasis without paralysis of accommodation, and local anæsthesia. It is frequently employed either by injection or local application for the purpose of relieving the pain attending the removal of foreign bodies or hypertrophies from the eye, nose, mouth, pharynx, or larynx. It may be employed in the eye when any operation is to be performed. It may also be used by hypodermic injection for the amputation of fingers or toes, or for the removal of small tumors. When a finger or toe is to be amputated, a rubber band should be placed tightly about the base of the digit to prevent the cocaine which is injected into the part gaining access to the general circulation. After a few minutes, during which time the nerve of the part becomes benumbed, the operation is rapidly performed, and on its conclusion the rubber band is loosened so as to allow slight hemorrhage to take place, thereby washing the parts free from cocaine. The rubber band is now readjusted to control hemorrhage, and the wound closed with proper antiseptic precautions. Cocaine has recently been injected in the subarachnoid space for the purpose of producing spinal anæsthesia, but this procedure may cause alarming symptoms, and there is possibility of infection of the spinal cord.

Coca or cocaine is not largely employed in internal medicine, but may be given as a temporary stimulant during the typhoid state of the low fevers. While its physiological action would lead us to believe that it is an invaluable stimulant in cases of collapse, clinical experience has shown that it is not particularly useful under these circumstances, as it not infrequently produces untoward and unexpected effects which are harmful in their character. Cocaine is said to be a good stimulant and anti-emetic in the treatment of yellow fever, and it enjoys an excellent reputation in the treatment of the vomiting of pregnancy, that following anæsthetization, and that accompanying acute gastric irritation. It has been employed in cases in which great mental or physical strain was to be borne, and in the treatment of the "opium habit," but should be given cautiously lest the patient develop the cocaine-habit. Coca has also been recommended in the treatment of hysteria, melancholia, and allied nervous conditions, but is of little benefit in any of them.

Under the name "infiltration anæsthesia," Schleich, a German surgeon, has introduced the employment of very weak solutions of cocaine mixed with morphine and common salt, for the purpose of benumbing peripheral sensory nerves not only by the action of the cocaine and morphine, but also by the pressure which is exerted upon them by the fluid injection. The advantage of Schleich's fluid is that the danger of cocaine and morphine-poisoning is avoided by reason of the very weak solution employed. Schleich uses the following solutions according to the degree of anæsthesia required:

	No. 1.	No. 2.	No. 3.
Cocaine hydrochloride	gr. iv (0.25 Gm.)	gr. ij (0.10 Gm.)	gr. $\frac{1}{2}$ (0.01 Gm.)
Morphine hydrochloride	gr. ss (0.025 Gm.)	gr. ss (0.025 Gm.)	gr. $\frac{1}{10}$ (0.005 Gm.)
Sodium chloride	gr. iv (0.25 Gm.)	gr. iv (0.25 Gm.)	gr. iv (0.25 Gm.)
Sterilized distilled water	f℥iv (120 Cc.)	f℥iv (120 Cc.)	f℥iv (120 Cc.)

To each of these three solutions 3 minims of a 5 per cent. solution of carbolic acid are added. Solution No. 2 is the one commonly employed.

In some instances when cocaine is applied too freely, it suddenly produces loss of speech, blindness, nausea and vomiting, fainting and unconsciousness, and even epileptiform convulsions. Curiously enough, these accidents most frequently follow the instillation of cocaine into the urethra prior to urethral operations.

The treatment of poisoning by cocaine consists in the use of strong coffee, and, if the circulation fails, the employment of strychnine, ether, or alcohol. While the convulsions are present it is stated that nitroglycerin may be given hypodermically with advantage.

Because of the pleasant effects which cocaine produces when taken hypodermically or by the mouth, the cocaine-habit is not rarely met with, many persons becoming slaves to the use of this drug. Often its abuse is combined with that of morphine. The symptoms of the cocaine-habit consist in a great loss of flesh, circulatory disorders, insane delusions and hallucinations, and sometimes collapse. The nervous breakdown of the patient under the continued use of this remedy is even more rapid than when morphine is abused.

As an anæsthetic for use in the eye, the amount used is from 3 to 5 minims (0.20–0.3 Cc.) of a 1 to a 4 per cent. solution. The same strength solutions may be employed in the nose and throat; but in the rectum and vagina 10 per cent. solutions are preferable. In the urethra it is not safe to use a solution stronger than 1 or 2 per cent., as the drug is sometimes rapidly absorbed.

The internal dose of cocaine is from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.), and of fluidextract of coca from $\frac{1}{2}$ to 1 fluidrachm (2–4 Cc.).

Allied Products.—No part of the plant other than the leaves is in use, though small quantities of alkaloid occur in the bark of the root and stem and in the fruit. None occurs in the wood. The genus *Erythroxylon* contains some 140 species, bearing 170 names. By far the greater number have not been tested for the presence of alkaloids nor for properties similar to those discussed above. Several, however, are known to share those properties to some extent. Under the names *Te*, *Haya*, etc., the leaves of *E. Popayennensis* Poepp., and some others which are undetermined, are used similarly in various parts of South America. One (Fig. 127, *b*), cultivated to some extent in the West Indies and in Java, but not an article of commerce, in this country at least, appears to be a form or a derivative of *E. Carthaginense* Jacq. This is probably the variety which, produced in Java, is reported to contain *benzoyl-pseudotropeine* ($C_{15}H_{19}NO_2$).

In Ceylon, the dried leaves of *E. lucidum* Moon (*Sethia acuminata* Arn.) are given in 15 grain (1 Gm.) doses, as an anthelmintic, and the fresh juice is also administered for the same purpose.

COCAINA, *U. S., Br.*—Cocaine.

Cocainum, Benzoyl-methyl-ecgonine, Methyl-benzoyl-ecgonine.—Cocaine, Fr.; *Cocain*, G.

Formula, $C_{17}H_{21}NO_4$ or $C_8H_{12}(C_6H_5CO)NO.COOCH_3$. Molecular weight, 300.92.

An alkaloid, $C_{17}H_{21}NO_4$, obtained from the leaves of *Erythroxylum Coca* Lam. and It is also obtained synthetically from ecgonine.

The alkaloid was originally called *erythroxyline* by its discoverer, Gaedeke (1855).

Preparation.—The early process of Niemann (1860) (*Nat. Disp.*, 5th ed., p. 504), and that of Lossen (1865), have been supplanted by more economical methods. In Squibb's process the coarsely ground leaves are exhausted of their alkaloidal content by repercolation with an aqueous 5 per cent. solution of sulphuric acid, and the concentrated extract thus obtained is thoroughly agitated with pure coal oil (kerosene oil) and an

excess of sodium carbonate. The liberated alkaloid is retained by the coal oil quite free from coloring-matter, and recovered by repeatedly agitating the oil with acidulated water, and again precipitating the alkaloid by sodium carbonate in the presence of ether. Upon distillation the ether solution yields cocaine in the form of a yellowish-brown crystalline mass, which may be purified by re-solution in acidulated water, decolorized with animal charcoal, and again precipitated by means of sodium carbonate, and dissolved in ether or hot alcohol, from which it is obtained in the form of crystals. A method was patented by Henriques (*Pharm. Centralh.*, 1895, 92), in which the alkaloid is extracted from the leaves by treatment with a solution of a zinc salt, and this precipitated with a sulphocyanide; or the leaves may be exhausted with a solution of a sulphocyanide and precipitated with a zinc salt, the alkaloid in both instances being precipitated as an insoluble double sulphocyanide of cocaine and zinc. At present much of the cocaine is obtained as crude cocaine in South America by methods similar to Squibb's, and exported to foreign factories for purification. Since Liebermann and Geisel (*Ber.*, 1888, xxi. 3196) have shown that the amorphous alkaloidal by-products can be hydrolyzed into *ecgonine* by boiling with hydrochloric acid and subsequently converted into cocaine, the by-products have become valuable. In Einhorn's process (*Ber.*, 1888, xxi. 3335) the ecgonine is converted into ecgonine hydrochloride, and the solution of the latter in methyl alcohol subjected to a current of dry hydrochloric acid gas, producing the hydrochloride of ecgonine methyl-ester. The latter is heated with an equal weight of benzoyl chloride, and the fused mass poured into water, the solution filtered, and the *cocaine* precipitated from the filtrate by ammonia and recrystallized from alcohol. Cocaine has also been prepared synthetically by Merck, by heating ecgonine, benzoic anhydride, and methyl iodide to 100° C. (212° F.) in sealed tubes for 10 hours.

Properties.—Cocaine crystallizes from alcohol in the form of colorless monoclinic prisms, which are soluble in 600 parts of water, 5 parts of alcohol, and in 3.8 parts of ether at 25° C. (77° F.); very soluble in chloroform and warm alcohol; also soluble at 80° C. (176° F.) in 260 parts of water (U. S.). Insoluble in glycerin, soluble in 10 parts of alcohol (90 per cent.), in 4 parts of ether, in ½ part of chloroform, in 12 parts of olive oil, and 14 parts of oil of turpentine (Br.); soluble in benzene, toluene, carbon disulphide, and carbon tetrachloride; insoluble in lard and vaseline (*Pharm. Jour.*, 1896, p. 28). Cocaine on being kept in solution for some time, or by boiling with acids or alkalies, is hydrolyzed into methyl alcohol, benzoic acid, and ecgonine. The latter has a sweetish taste, and is soluble in water, but insoluble in alcohol. The hydrolysis is illustrated by the equation: $C_{17}H_{21}NO_4$ (cocaine) $+ 2H_2O = C_9H_{15}NO_3$ (ecgonine) $+ C_7H_6O_2$ (benzoic acid) $+ CH_3OH$ (methyl alcohol). Cocaine melts at 98° C. (208.4° F.), U. S.; 96° to 98° C. (204.8–208.4° F.), Br.. Heated to a much higher degree, it volatilizes, with decomposition of the greater portion. It is strongly alkaline in reaction, and may be titrated with acids direct, with litmus as an indicator. Applied to the tongue, it has a bitter taste, and produces a sudden and characteristic numbness. Its solutions are strongly lævorotatory. Dissolved in chloroform, $S_d = 15°$. It is a monacid base, and yields easily crystallizable salts, the most common of which is the hydrochloride.

Tests.—The purity of cocaine is determined best by its melting-point, and, after conversion into the hydrochloride, by the tests given under that salt (which see).

For the action and uses of cocaine, see COCA.

Salts of Cocaine.—Besides the hydrochloride, which is the only salt of cocaine that has received recognition in any of the pharmacopœias, a number of other combinations have been placed upon the market, and are in use to a more or less limited extent, thus: *Cocaine-aluminum sulphate* or *Cocaine alum*, $Al(SO_4)_2C_{17}H_{21}NO_4 + 12H_2O$; *Cocaine benzoate*, $C_{17}H_{21}NO_4.C_7H_6O_2$; *Cocaine borate*, $C_{17}H_{21}NO_4.(H_3BO_3)_2$; *Cocaine cantharidate*, $(C_{17}H_{21}NO_4)_2 + C_{10}H_{12}O_4$; *Cocaine citrate*, $(C_{17}H_{21}NO_4)_3H_3C_6H_5O_7$; *Cocaine hydrobromide*, $C_{17}H_{21}NO_4.HBr$; *Cocaine lactate*, $C_{17}H_{21}NO_4.HC_3H_5O_3$; *Cocaine nitrate*, $C_{17}H_{21}NO_4.HNO_3$; *Cocaine oleate*, $C_{17}H_{21}NO_4.HC_{18}H_{33}O_2$; *Cocaine phenate* or *phenylate*, $C_{17}H_{21}NO_4.C_6H_5(OH)$; *Cocaine salicylate*, $C_{17}H_{21}NO_4.HC_7H_5O_3$; *Cocaine stearate*, $C_{17}H_{21}NO_4.HC_{18}H_{35}O_2$; *Cocaine sulphate*, $(C_{17}H_{21}NO_4).H_2SO_4$.

Of the foregoing salts, the cocaine borate is preferred to the hydrochloride in solutions intended for the eye and for subcutaneous use, on account of their greater stability. Cocaine oleate and stearate are preferred for use in ointments and suppositories; the normal oleate, containing about 52 per cent. of cocaine, is rarely used, a solution of the alkaloid in oleic acid, of either 5, 10, or 25 per cent. strength, being preferred, which can be quickly pre-

pared by warming 5, 10, or 25 grains of cocaine alkaloid with 95, 90, or 75 grains of oleic acid in a dish on a water-bath. Since hydrochloric acid is incompatible with silver salts, cocaine nitrate should be used in place of the hydrochloride in connection with silver nitrate whenever such a combination is desired. Cocaine phenate or cocaine-phenol is obtained by warming 12 parts of crystallized carbolic acid on a water-bath until it melts and adding 38 parts of cocaine alkaloid. It occurs as a yellow viscid mass, insoluble in water but soluble in alcohol, and is recommended especially for use in dentistry.

Allied Products.—CINNAMYLCOCAINE. $C_6NH_{10}CHO(C_9H_7O)CH_2COOCH_3$.—This alkaloid, which occurs in coca leaves, may also be produced synthetically by substituting cinnamyl chloride for benzoyl chloride in the process for the synthetic manufacture of cocaine from ecgonine. It forms lustrous prismatic crystals, melting at 121° C. (249.8° F.). Owing to its ready oxidation by potassium permanganate, the presence of cinnamylcocaine in cocaine may easily be detected.

DEXTRO-COCAINE.—While, as stated above, the cocaine found in coca leaves, and also when artificially made from ecgonine, is lævorotatory, a dextrorotatory variety has also been produced, which differs in many respects from the other. It is obtained by first acting on ecgonine for 2 or 3 days with a 30 per cent. potassium hydroxide solution, whereby dextro-ecgonine is formed, and then proceeding as directed above for the synthetic manufacture of cocaine from ecgonine. Dextro-cocaine melts at 44° C. (111.2° F.). Its hydrochloride, which melts at 205° C. (401° F.), is far less soluble in water than the official cocaine hydrochloride.

HOMOCOCAINE. *Ethyl-benzoyl-cocaine.* $C_{18}H_{23}NO_4$.—This base, also known as coca-ethyline, is a synthetic product obtained by substituting ethyl alcohol for methyl alcohol in the process for making cocaine from ecgonine, mentioned above, and then benzoylating the ecgonine ethyl-ester formed. The crystals melt at 109° C. (228.2° F.). The anæsthetic action of homococaine and its salts is relatively weaker than that of cocaine.

TROPACOCAINE. *Benzoyl-pseudotropeine.* $C_8H_{14}NO(C_7H_5O)$.—This alkaloid, found chiefly in the coca leaves of Java, differs from cocaine markedly in its constitution, and also in its therapeutic effects in possessing slight mydriatic properties. Upon being heated with hydrochloric acid, it is split up into benzoic acid and tropine.

ISATROPYLCOCAINE. $C_{19}H_{23}NO_4$.—An amorphous base found in coca leaves, which yields amorphous salts and is difficultly soluble in ammonia water. Its presence in cocaine is readily detected by the Maclagan ammonia test described under Cocaine Hydrochloride. Isatropyl-cocaine is not oxidized by potassium permanganate, as in the case of cinnamylcocaine. It is very poisonous.

ANESON. *Anesin.*—This name has been applied in the trade to a 2 per cent. aqueous solution of tertiary trichlorbutyl alcohol or acetone-chloroform, $(CH_3)_2 : COH.CCl_3$, which has been recommended as a substitute for cocaine. It cannot be compared, however, in anæsthetic power with a 5 per cent. solution of cocaine hydrochloride, although it is well suited for some minor operations. The solution is said to be non-toxic and has no irritating effect on the eye.

COCAINÆ HYDROCHLORIDUM, *U. S.*, *Br.*—Cocaine Hydrochloride.

Cocaïnum hydrochloricum, P. G.—*Chlorhydrate de cocaine*, Fr.; *Cocainhydrochlorid*, G.

Formula, $C_{17}H_{21}NO_4.HCl$ or $C_8H_{13}(C_6H_5CO)NO.COOCH_3.HCl$. Molecular weight, 337.10.

The hydrochloride of the principal alkaloid obtained from the leaves of *Erythroxylon Coca* and its varieties.

Preparation.—Cocaine hydrochloride may be obtained in several ways: The alkaloid cocaine may be dissolved in alcohol, the solution neutralized with an alcoholic solution of hydrochloric acid gas and then set aside to crystallize, or the salt precipitated by addition of ether. The dry alkaloid may also be dissolved in ether or petroleum ether, and dry hydrochloric acid gas then passed into the solution, when the salt will separate out. Or the alkaloid may be dissolved in just sufficient water with the aid of hydrochloric acid, and the solution then evaporated to dryness in vacuo over sulphuric acid or calcium chloride, the residue being subsequently recrystallized from alcohol.

Properties.—Cocaine hydrochloride crystallizes from alcohol in short, thin, transparent *anhydrous* prisms, and from water in needle-shaped crystals with 2 molecules of water of crystallization. The official salt of the U. S., Br., and P. G. is anhydrous, while that of the French contains 2 molecules or 9.59 per cent. of water. It occurs commercially in transparent, monoclinic prisms or flaky, lustrous leaflets, or as a white crystalline powder, permanent in the air and containing no water of crystallization. It is odorless, has a saline, slightly bitter taste, and produces on the tongue a tingling sensation followed by numbness of several minutes' duration. It is soluble at 25° C.

(77° F.) in 0.4 part of water, 2.6 parts of alcohol, or 18.5 parts of chloroform; at 80° C. (176° F.) in 0.1 part of water, and at 60° C. (140° F.) in 1.4 parts of alcohol (U. S.). Soluble in half its weight of cold water and in 4 times its weight of 90 per cent. alcohol or of glycerin (Br.). It is insoluble in benzene, petroleum benzin, ether, and olive oil. Its aqueous solution is neutral to litmus-paper and is lævogyrate. Cocaine hydrochloride melts at 189.9° C. (373.8° F.), U. S., 180° to 186° C. (356°–366.8° F.), Br., 183° C. (361.4° F.), P. G., 181.5° C. (358.7° F.), Fr. Cod., forming a light brownish-yellow liquid, and when ignited burns without residue. Minute quantities of impurities may reduce the melting-point to 180° C. (356° F.), U. S. "If silver nitrate test-solution be added to the aqueous solution of the salt (1 in 100), a white precipitate is produced, which is insoluble in nitric acid. On adding 5 drops of a 5 per cent. solution of chromic acid to 5 Cc. of a solution of cocaine hydrochloride (1 in 50), a yellow precipitate will be produced, which redissolves on shaking; on now adding 1 Cc. of hydrochloric acid, a permanent orange-colored, crystalline precipitate will be formed. On adding a solution of potassium chromate (1 in 20) to a hydrochloric acid solution of the salt, orange-yellow leaflets of cocaine chromate are precipitated. If mercuric chloride test-solution be added to an aqueous solution of the salt, a white flocculent precipitate is produced. Cocaine hydrochloride is not colored by sulphuric acid, but if a crystal be heated with sulphuric acid, in a test-tube, vapors are produced, from which benzoic acid is deposited on cooling. If 3 drops of palladious chloride test-solution, with 3 Cc. of chlorine-water, be added to 3 drops of an aqueous solution of the salt (1 in 20), a red precipitate is produced. A crystal of the salt dissolved in alcohol yields when stirred with a piece of potassium hydroxide an odor of ethyl benzoate. When 0.01 Gm. of the salt is dissolved in 2 drops of water, the addition of 1 Cc. of a solution of potassium permanganate (1 in 30) produces a violet precipitate, which appears brownish violet when collected on a filter."—U. S. "Cocaine hydrochloride affords a yellow precipitate with solution of auric chloride; a white precipitate with solution of ammonium carbonate, and also with solution of borax. Its aqueous solution yields with picric acid a yellow precipitate, becoming crystalline on standing. Moistened with nitric acid, the mixture evaporated to dryness, and a drop of alcoholic solution of potassium hydroxide added, a characteristic odor is evolved more or less recalling that of peppermint."—Br. Cocaine hydrochloride precipitates Prussian blue from a mixture of ferricyanide and ferric chloride. If a drop of ferric chloride be added to a solution of the salt and the liquid boiled, an intense red color will be developed (Lerch and Scharges).

Tests.—Besides the characteristic reactions mentioned above, cocaine hydrochloride should respond to the following tests for purity: If 0.1 Gm. of the salt be dissolved in 5 Cc. of distilled water, containing 3 drops of diluted sulphuric acid, the addition to this solution of 1 drop of potassium permanganate solution (1 in 100) will produce a violet color, which should not fade in half an hour (limit of cinnamyl-cocaine). If 0.1 Gm. of the salt be dissolved in 85 Cc. of distilled water, in a beaker, and 4 drops of ammonia-water added, and the solution stirred vigorously for fifteen minutes, with the occasional rubbing of the sides of the beaker with a stirring rod, a crystalline precipitate of cocaine should be formed, and the supernatant liquid should be perfectly clear (limit of isatropyl-cocaine). The presence of 0.5 per cent. of isatropyl-cocaine will prevent the formation of nearly all of the precipitate, and will cause the supernatant liquid to be opalescent.—U. S. Dried for 20 minutes at 95.6° to 100° C. (204°–212° F.), the salt should not lose more than 1 per cent. of moisture (Br.). Maclagan's ammonia test given above is extensively used, and is considered sufficient for all commercial lots of cocaine hydrochloride.

Schaeffer's chromic acid test, based upon the relative solubility of cocaine chromate (1 in 500) as compared with that of the chromates of the objectionable alkaloids (1 in 5000), is applied as follows: 0.05 Gm. of cocaine hydrochloride is dissolved in 20 Cc. of distilled water, mixed with 5 Cc. of a 3 per cent. solution of chromic acid (freshly prepared), and then 5 Cc. of 10 per cent. hydrochloric acid added—the temperature of the mixture being kept at 15° C. (59° F.). In the presence of more than traces of the foreign coca alkaloids the solution becomes cloudy at once, or in a few minutes, according to the proportion present.

Action and Uses.—The medicinal properties and therapeutic effects of this salt are fully described under Coca (which see).

COCCUS, *U. S.*, *Br.*—Cochineal.

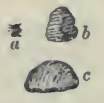
Coccionella.—Cochenille, G,, Fr.; *Cochinilla, Grana*, Sp.; *Cochinilha*, Port.; *Coccinigliа*, It., Swiss.

The dried female insect *Pseudococcus cacti* (L.) Burmeister (Order *Hemiptera*).

Cochineal is official in most pharmacopœias. The Br. P. allows 6 per cent. of ash.

Origin.—The cochineal insect is indigenous to Mexico and Central America, and has been introduced into and is cultivated in some of the West India islands, the Canaries, Algiers, and southern Spain. It feeds on different species of cactus, particularly on *Nopalea cochinillifera* (Mill.) Salm-Dyck (*Opuntia c.* Mill.) and other "prickly pear" cactuses. The male insect is very small, winged, and bears 2 long bristles upon the tail. The female is about twice as large, wingless, and without the bristles. She lives attached continuously to the same point upon the plant, and her eggs, several thousand in number, hatch within her body after death. The body is entirely concealed by a white wax, formed into a fluffy, cotton-like mass. Two methods are employed for killing the insects after they are brushed off, resulting in different forms of the commercial product. If carefully killed by fumes of sulphur or other substances, the wax is retained, though compacted to the body, and we get the so-called "silver-grain" form. If dipping in boiling water is practised, the wax is removed, this relatively increasing the percentage of active constituent by reduction of total weight, and we get the "black-grain" article. Other varieties of commerce depend upon the age of the insects when collected, the older ones being inferior in yield of coloring-matter, and upon a wild or cultivated origin, the *Granilla* ("little grain") or *Grana sylvestra* ("wild grain") being the wild ones, and inferior. In cultivation, a supply of insects is preserved under cover during the rainy season, for purposes of propagation. Three crops are usually secured during the dry season.

FIG. 127.



Coccus cacti: female insect (Nat.): *a*, before, and *b*, after impregnation, dry; *c*, latter after soaking in water.

Description.—About 5 Mm. ($\frac{1}{5}$ In.) long, nearly as broad and half as thick, angularly elliptical in outline, the lower surface flat, a little concave, the upper convex, transversely wrinkled, or ringed after swelling by soaking in water, which causes 3 pairs of legs to become visible; gray- or silvery-purple, or purple-black, and imparting a red coloration to water, alcohol, or ammonia water, slightly to ether, but not to fixed or volatile oils; readily pulverizable to a dark-red powder; odor faint, characteristic; taste bitterish.

No insoluble powder should separate upon macerating in water, and the ash should not exceed 6 per cent.

Adulterants.—Of the entire cochineal, the *Grana sylvestra* is to be regarded as an adulterant or substitute. Although permitted by our definition, it is excluded by the description as to size. An artificial cochineal, very readily identified, is made by coloring the exhausted powder with rosaniline, forming into grains, and dusting with some white powder. Various methods of adulteration by coating with heavy mineral powders of suitable color are in vogue. This is so ingeniously done as to cause the foreign matter to be concealed in the folds. Maceration in water, however, usually frees it. Adulteration of powdered cochineal is less readily detected, and the only certain and practicable method of examination is the determination of the percentage of coloring-matter.

Constituents.—The peculiar wax *coccerin*, $C_{30}H_{60}(C_{31}H_{61}O_3)_2$, which coats the insect, amounts to from 1 to 2 per cent. in the silver variety, 0.5 to 1 per cent. in the black, and 4.2 per cent. in the inferior *granilla*. It is soluble in benzene, but nearly insoluble in ether. The insect yields 1.5 to 2 per cent of myristin, 4 to 6 per cent. of fixed oil, fats, gum, a volatile acid, and *carminic acid* or *carmine-red* ($C_{11}H_{12}O_6.2H_2O$), amounting to 8 or 10 per cent. in the silver coccus. This acid has a bright purplish-red color, unalterable in dry air, and is soluble in water, alcohol, and alkalies, slightly so in ether, and not at all in fixed and volatile oils. It forms colored precipitates with most metallic salts, that from aluminum hydroxide being called *lake*. It was long believed to be a glucoside, but it is now known that the reducing substance separated by prolonged boiling with sulphuric acid, is not a sugar. P. Mayer remarks that carmine is not found in any organ apart from the diffuse fatty body and the yolk.

Carmine may be precipitated from a decoction of cochineal by alum, cream of tartar, or potassium binoxalate. It should be entirely soluble in ammonia water. Fietler

found that the amount of moisture in 5 samples of pure carmine ranged from 13.15 to 20.48 per cent., and averaged 16.36 per cent. The ash ranged from 8.1 to 10.51 per cent., the coloring-matter from 57.4 to 67.2 per cent. Alumina was present to the extent of from 25.95 to 43.18 per cent. Commercial carmine is extremely subject to adulteration of many kinds. The restriction of the ash to 9 per cent. and the absolute exclusion of barium or lead (not tin) are regarded by Fietler as the most useful precautions. It should be soluble in dilute ammonia, leaving but few flakes of insoluble matter.

Pharmaceutical Preparations.—Cochineal Color, N. F.; Cochineal Test-solution, U. S. P.; Solution of Carmine, N. F.; Tincture of Cochineal, Br. P.

Action and Uses.—Cochineal is rarely employed in medicine at the present day. Formerly it was supposed to possess certain anodyne properties, and was used in the treatment of whooping-cough, hiccough, and neuralgia.

It may be given to infants in doses of $\frac{1}{4}$ grain (0.015 Gm.) 3 times daily. The adult dose of the tincture is from 30 to 60 minims (2–4 Cc.); but as much as 4 fluidrachms (16 Cc.) may be employed.

The females of *C. ilicis* Fabricius (*Kermes*, *Chermee*, or *Alkermes*), obtained in the Mediterranean region from trees of *Quercus coccifera* L., are similarly used, and yield a similar coloring-matter. They are several times larger than the official, globular-ovoid, and nearly smooth.

CODEINA, *U. S.*, *Br.*—Codeine.

Codeïnum.—*Codeina*, *Methyl-morphine*, E.; *Codéine*, Fr.; *Kodein*, G.; *Codeina*, It., Sp.

Formula, $C_{18}H_{21}NO_3.H_2O$ or $C_{17}H_{17}NO(OH).OCH_3 + H_2O$. Molecular weight, 314.83.

An alkaloid contained in opium to the extent of 0.1 to 2 per cent. It is prepared from opium, and also artificially from morphine.

Codeine was discovered as a constituent of opium by Robiquet (1832), and prepared artificially from morphine by Grimaux (1881), by heating an alcoholic solution of morphine with sodium hydroxide and methyl iodide.

Preparation.—In preparing morphine by Gregory's process (see Morphina), after precipitating with calcium chloride, the hydrochlorides of morphine and codeine crystallize together, and on redissolving them in water and adding ammonia, morphine alone is precipitated. The ammoniacal filtrate is concentrated, the crystallizing codeine hydrochloride freed from ammonium chloride, then dissolved in hot water, and decomposed by potassium hydroxide, when a portion of the codeine will crystallize on cooling, but the greater part separates as an oily liquid, which gradually solidifies. The mother-liquor yields a further quantity of the same alkaloid, contaminated with morphine. The alkaloid is washed with cold water, then dissolved in ether, the ethereal solution mixed with water, and evaporated to crystallize.

Codeine is prepared synthetically from morphine, according to a recent patent, by adding a solution of 50 Gm. of potassium hydroxide in 800 Gm. of methyl alcohol to a solution of 285 Gm. of morphine and 132 Gm. of nitroso-methyl-urethane in 1000 Gm. of methyl alcohol. On completion of the reaction the methyl alcohol is removed by distillation, and the codeine extracted from the residuum by suitable solvents and crystallized. It is also prepared artificially by the action of methyl iodide or methyl chloride upon an alkaline solution of morphine—process of Dott; as well as by the action of sodium methylsulphate upon an alkaline solution of morphine—process of Knoll.

Properties.—Codeine occurs in the form of white or nearly translucent rhombic prisms or octahedral crystals, which are odorless, have a slightly bitter taste, and a strong alkaline reaction to moist litmus-paper. The crystals are soluble at 25° C. (77° F.) in 88 parts of water, 1.6 parts of alcohol, 12.5 parts of ether, and 0.66 part of chloroform; at 80° C. (176° F.) in 59 parts of water and at 60° C. (140° F.) in 0.92 part of alcohol (U. S.). The British Pharmacopœia gives the solubility at 15.5° C. (60° F.) as 1 in 80 of water or 30 of ether. It is also soluble in 17 parts of boiling water, 10 parts of benzene, 10 parts of oil of anise (morphine, insoluble) (L. Fouquet), and 85 parts of ammonia-water, and freely soluble in amyl alcohol, methyl alcohol, and carbon

disulphide, but insoluble in petroleum benzin and aqueous solution of potassium or sodium hydroxide. Codeine crystallizes anhydrous from dry ether or carbon disulphide, but from aqueous solutions with 1 molecule (5.67 per cent.) of water of crystallization. The latter form is official in the Br. and U. S. P. When heated to 100° C. (212° F.) codeine loses its water of crystallization. It melts, in an insufficient amount of boiling water for complete solution, to an oily liquid, but when heated alone it fuses at 155° C. (311° F.) (152°–153° C.) (305.6°–307.4° F.) (Hager), and on ignition burns without residue. Its aqueous solutions react strongly alkaline, precipitate the salts of copper, lead, iron, and other metals, and liberate ammonia from ammonium salts. It may be titrated direct with acids, using litmus as an indicator. Its solutions are strongly lævorotatory, the degree being much affected by the nature of the solvent, $S_3 = -100.9°$ in chloroform, and —122.9° in alcohol. Codeine does not separate iodine from iodic acid, and is not colored blue by ferric chloride (difference from morphine). Its solution in absolutely pure sulphuric acid remains colorless for several days, but on heating a violet color is developed; in the presence of traces of nitric acid or of iron the cold solution changes to green and blue, and deposits a blue precipitate. Erdmann's reagent, used for this test, consists of 20 Gm. of pure sulphuric acid and 10 drops of a mixture made with 6 drops of nitric acid (specific gravity 1.15) and 100 Gm. of water. Codeine is dissolved by sulphuric acid containing sodium molybdate (Fröhde's reagent) to a liquid having at first a dirty-green color, which after a while becomes pure blue, and gradually fades within a few hours to pale yellow. For the testing of alkaloids, Fröhde's reagent is prepared best by adding 1 Mg. of sodium molybdate to 1 Cc. of pure sulphuric acid. The yellow solution of codeine in nitric acid when heated contains *nitro-codeine*, $C_{18}H_{20}(NO_2)NO_3$. Codeine yields with chlorine water a colorless solution, which changes to red-brown on the addition of ammonia. If codeine is added to a solution of a morphine salt, precipitation of morphine occurs, and if the former alkaloid in powder be added to a solution of ammonium chloride, solution takes place and the odor of ammonia becomes perceptible. Codeine heated with an equal weight of paranitroso-dimethylaniline in alcohol produces *codeine-violet* (P. Cazaneuve, *Compt. rend.*, 113, pp. 747–749). Codeine dissolves with a violet color in concentrated sulphuric acid containing formaldehyde (3 Cc. of sulphuric acid + 3 drops of formaldehyde, Marquis, *Jour. Chem. Soc.*, 1900, p. 121), morphine producing a purple-red to pure blue; in 20 per cent. solution of benzylaldehyde in absolute alcohol followed by sulphuric acid it produces yellow to blood-red streaks (Melzer); in 5 per cent. solution of potassium perruthenate in concentrated sulphuric acid it produces a blue color after warming, morphine giving a green color (Brociner, *Zeitschr. Anal. Chem.*, 37, p. 62); mixed with a few drops of a solution of sodium hypochlorite and a few drops of sulphuric acid, codeine presents a persistent blue coloration (L. Raby); dissolved in concentrated sulphuric acid containing 5 per cent. of ammonium selenite, codeine gives a magnificent green color (Lafon). It forms a condensation-product, *dicodeylmethane*, with formaldehyde.

Codeine forms crystallizable salts with acids, the solutions of which give precipitates with the general alkaloidal reagents.

Tests.—Codeine dissolves without production of color in pure concentrated sulphuric acid; but if about 2 Cc. of this solution are poured into a small porcelain capsule, and 1 drop of highly diluted nitric acid (made by adding 1 drop of nitric acid to 200 Cc. of water) added, a bluish or blue tint will be developed. Another portion of this solution, of about 2 Cc., gently warmed, and mixed with 1 drop of a mixture of 1 volume of ferric chloride test-solution and 19 volumes of water, likewise assumes a bluish or blue tint (difference from morphine). On dissolving a small crystal of potassium ferricyanide in 10 Cc. of water, adding 1 drop of ferric chloride test-solution, and then 1 Cc. of codeine solution (1 in 100), no blue color should be produced at once (absence of morphine). On sprinkling 0.05 Gm. of codeine upon 2 Cc. of nitric acid (specific gravity 1.200), the crystals will turn red, but the acid, even when warmed, will acquire only a yellow color (difference from and absence of morphine).—U. S.

A 2 per cent. solution of codeine in water acidulated with a few drops of hydrochloric acid gives a whitish precipitate with solution of potassium hydroxide, but not with solution of ammonia. A saturated solution of codeine in water acidulated with hydrochloric acid should give no blue color, but only gradually a dull-green, on the addition of test-solution of ferric chloride and a very dilute solution of potassium ferricyanide (absence of morphine and other impurities).—Br. P.

Pharmaceutical Preparation.—Syrup of Codeine, N. F.

Action and Uses.—In its physiological action, codeine closely resembles morphine, with which it is sometimes contaminated. It is possessed of less narcotizing power, however, and does not arrest secretion in the respiratory and intestinal tracts. If given in overdose, it produces gastric disturbance, cerebral congestion, stupor or delirium, contracted pupils, and tremors. In the lower animals it causes tetanus, followed by paralysis of the peripheral motor nerves. Codeine is employed quite largely to relieve nervous cough and other manifestations depending upon an irritable condition of the nervous system. It is an excellent remedy in many cases of diabetes mellitus, but in some cases proves useless. It should, however, be given a trial in the treatment of this condition. It may be employed with success where the cough of tuberculosis or bronchitis is excessive. Because of the fact that codeine constipates but slightly, it may be given to relieve the pain of intestinal colic, enteralgia, and other painful conditions. Being variable in its composition, the beginning dose should not exceed from ½ to 2 grains (0.03–0.12 Gm.). For the relief of cough, this dose is quite sufficient, but in the treatment of diabetes it should be rapidly increased until the glycosuria has diminished. Sometimes as much as 20 or 30 grains (1.3–2 Gm.) are required daily.

Derivative Products and Unofficial Salts of Codeine.—Apocodeine. $C_{18}H_{19}NO_2$ or $CH_3O.C_{17}H_{16}NO$.—This substance was discovered by Matthiessen and Wright (1869), and is obtained by heating codeine hydrochloride with a concentrated solution of zinc chloride for about 15 minutes at a temperature of 180° C. (356° F.). The mass is cooled, dissolved in water, made alkaline with an excess of sodium carbonate solution, and the free base extracted with chloroform or ether. After recovery of the solvent, the residue, consisting of brown amorphous masses, soluble in alcohol but almost insoluble in water, is apocodeine. Recent researches indicate that apocodeine is a mixture of bases. Apocodeine hydrochloride, $C_{18}H_{19}NO_2.HCl$, may be obtained by dissolving apocodeine in sufficient dilute hydrochloric acid to produce a neutral solution, and evaporating the same to dryness. It occurs as a yellowish-gray amorphous powder, readily soluble in water and alcohol, and possessing properties similar to those of apomorphine hydrochloride.

Pseudocodeine. $C_{18}H_{21}NO_3 + H_2O$ or $CH_3O.C_{17}H_{18}NO_2 + H_2O$.—If moderately dilute sulphuric acid be allowed to act on codeine at the temperature of boiling water, pseudocodeine will be produced, which occurs as a white crystalline base, soluble in alcohol and forming crystallizable salts.

Codeinæ Hydrobromidum. *Codeinum hydrobromidum. Codeine hydrobromide*, E.; *Kodeinhydrobromid. Bromwasserstoffsaures Kodein*, G. $C_{18}H_{21}NO_3.HBr + 2H_2O$.—Codeine hydrobromide is prepared by dissolving and neutralizing 10 parts of codeine with 51 parts of warm 5 per cent. hydrobromic acid. The salt crystallizes out on cooling, and may be purified by recrystallization from 70 per cent. alcohol. It occurs as white glistening needle-like crystals. It is readily soluble in water and dilute alcohol.

Codeinæ Hydrochloridum. *Codeinum hydrochloridum. Codeine hydrochloride*, E.; *Kodeinhydrochlorid*, G. $C_{18}H_{21}NO_3.HCl + 2H_2O$.—The salt is readily prepared by neutralizing codeine with hot dilute (12.5 per cent.) hydrochloric acid, the codeine hydrochloride crystallizing on cooling. It occurs as small white crystals, soluble in 26 parts of water, in less than its own weight of boiling water, and loses its water of crystallization slowly on drying at 100° C. (212° F.).

CODEINÆ PHOSPHAS, *U. S.*, *Br.*—Codeine Phosphate.

Codeïnum phosphoricum, P. G.; *Phosphate de codéine*, Fr.; *Kodeinphosphat, Phosphorsaures Kodein*, G.

Formula, $(C_{18}H_{21}NO_3)_3H_3PO_4 + 2H_2O$ or $(PO(OH)_3(C_{18}H_{21}NO_3)_3 + 2H_2O)$. Molecular weight, 430.

Phosphate of the alkaloid *codeine*, obtained from opium or prepared from morphine.

Preparation.—Dissolve 10 parts of codeine in 12.5 parts of phosphoric acid (25 per cent.), leaving the solution slightly acid in reaction, and add sufficient alcohol to precipitate the salt.

Properties.—The water of crystallization is variable, depending upon the conditions of the crystallization. The formula of the Br. P. salt is given as $(C_{18}H_{21}NO_3.H_3PO_4)_2 + 3H_2O$. Codeine phosphate contains about 70 per cent. of codeine, and occurs as fine, white, needle-shaped crystals, or crystalline powder, without odor, and having a bitter taste. It is soluble at 25° C. (77° F.). in 2.25 parts of water, 261 parts of alcohol,

1340 parts of ether, and in 6620 parts of chloroform; at 80° C. (176° F.) in 0.46 part of water, and at 60° C. (140° F.) in 97 parts of alcohol. The Br. P. gives the solubility as 1 in 4 parts of cold water, and the P. G. as 1 in 3.2 parts. At 100° C. (212° F.) it loses all of its water of crystallization; above 200° C. (392° F.) it becomes darker in color, and at 235° C. (455° F.) melts to a brown liquid, which rapidly volatilizes. Its aqueous solution reddens blue litmus-paper. If silver nitrate test-solution be added to an aqueous solution of codeine phosphate, a yellow precipitate is produced, which is soluble in dilute nitric acid; if, after the solution is decanted, ammonia-water be added, the precipitate is dissolved.—U. S.

Tests.—When dried at 100° C. (212° F.) it should not lose more than 8 per cent. of water, nor should it react for chloride or sulphate when its 5 per cent. aqueous solution, acidulated with nitric acid, is tested with test-solution of silver nitrate or barium chloride. If 0.2 Gm. of codeine phosphate be dissolved in 5 Cc. of water and 3 Cc. of potassium hydroxide test-solution, and the solution shaken out successively with 3 portions of chloroform (5 Cc. each), the combined chloroformic solutions evaporated to dryness in a tared dish, should yield not less than 0.13 Gm. of codeine (U. S.). It should dissolve without color in concentrated sulphuric acid. In an aqueous solution of codeine phosphate (1 in 20) silver nitrate causes a yellow, and potassium hydroxide a white precipitate (P. G.). The precipitate caused by potassium hydroxide in the aqueous solution should give the reactions characteristic of codeine. A solution of 1 grain of potassium ferricyanide and 1 drop of ferric chloride in 10 Cc. of water should not be colored blue upon the addition of 1 Cc. of an aqueous (1 per cent.) solution of codeine phosphate (P. G.). It should not be colored blue by ferric chloride test-solution (absence of morphine).—Br. P.

Action and Uses.—This salt is employed for the same purposes and in the same dose as CODEINE (which see).

CODEINÆ SULPHAS, *U. S.*—Codeine Sulphate.

Codeïnum sulfuricum.—Sulfate de codéine, Fr.; *Kodeinsulfat, Schwefelsaures Kodein*, G.

Formula, $(C_{18}H_{21}NO_3)_2.H_2SO_4 + 5H_2O$ or $SO_2.(OH)_2(C_{18}H_{21}NO_3)_2 + 5H_2O$. Molecular weight, 780.65.

The sulphate of an alkaloid obtained from opium or prepared from morphine by methylation. It should be kept in small, well-stoppered, amber-colored vials.—U. S.

Preparation.—Codeine sulphate may be prepared by dissolving the alkaloid codeine in warm water, and adding sufficient sulphuric acid to obtain a neutral liquid, which is concentrated and allowed to crystallize. 100 Gm. of crystallized codeine will require 16.54 Gm. of official (92.5 per cent.) sulphuric acid.

Properties and Tests.—Codeine sulphate occurs in long, glistening, white, needle-shaped crystals, rhombic prisms, or crystalline powder, efflorescing in the air, odorless, and having a bitter taste. It is soluble at 25° C. (77° F.) in 23 parts of water, and 1035 parts of alcohol, but is insoluble in chloroform and ether; at 80° C. (176° F.) it is soluble in 6.25 parts of water and at 60° C. (140° F.) in 340 parts of alcohol. The salt loses its water of crystallization at 100° C. (212° F.); chars, decomposes, and partially volatilizes above 200° C. (392° F.), without melting; the residue melts at about 278° C. (532.4° F.). Its aqueous solution is neutral to litmus-paper. If barium chloride test-solution be added to an aqueous solution of the salt, a white precipitate is obtained, which is insoluble in hydrochloric acid.—U. S. In all other respects it conforms to the reactions and tests mentioned under CODEINE (which see).

Action and Uses.—Codeine sulphate, being more soluble in water, is used in preference to the alkaloid itself. (See CODEINA.)

COLA.—Kola.

Semen (*Nuces*) *Colæ; Kola-nuts, Guru* (*Gooroo*) *nuts, Female cola, Soudan coffee, Bichy* (*Bissy*) *nuts*, E.; *Kola-nuss*, G.; *Noix de Cola* (*de Gourou*) Fr.; *Nuez de Cola*, Sp.

The recent or dried cotyledons of *Cola vera* Schum. or of *Cola acuminata* (Beauv.) Schott (*Sterculia a.* Beauv.; *Bichea solitaria* Stokes: *Lunanea Bichy*, DC.—Fam. *Sterculiaceæ*).

Origin.—From good-sized and handsome trees, natives of tropical Africa, and rather extensively cultivated in some other tropical countries, the second-named especially in the West Indies, where it is quite extensively naturalized. Commercial supplies come from Africa and the West Indies. The West Indian are larger and better-looking, but, according to Dohme's analysis, contain less caffeine. The fruit is a very large, rough, and woody, 3- to 8- (mostly 5-) celled dehiscent capsule, each cell containing from 1 to 3 seeds, the best varieties containing but 1. The seed-coats are thick and rather soft. The seeds are left for several days, when their coats partly decay or soften, and then are removed and the kernels washed. When fresh, the seeds are either white or purplish-red. The native use of the kernels is almost wholly in the fresh state, and usually after they have been caused to germinate, probably because they are then sweeter. Great quantities are now exported in the fresh condition. By careful treatment, packing, and storing, they can be preserved fresh for more than 3 months. For this purpose, they are thoroughly washed in the purest of water, drained, and packed in peculiar cane-baskets holding about a half-bushel. In the basket they are carefully enclosed in the large leaves of another species of Cola. These leaves not only prevent moulding and decay, but repel larval attacks, to which the fresh seeds are very liable. They do not long preserve their bright color, but change to a dull purplish-brown. For drying, their cotyledons (2 in *C. vera*, 3 or 4 in *C. acuminata*) are separated and exposed to the sun. When thoroughly dried, they can be easily and perfectly kept for any desired time.

FIG. 128.

Cola vera: edge of fresh kernel (Nat.).

FIG. 129.

Cola vera: inner face of dry cotyledon (Nat.).

Kola is used by the natives as a muscular stimulant or supporter, very much as coca is used in the Andes, and there is a very large domestic trade in it in Africa. The literature of its native use is now quite extensive.

Description.—The fresh kernels are preserved entire; that is, the cotyledons are not separated. They are 3 to 4 Cm. (about 1 to 1½ In.) long, nearly as broad and two-thirds as thick, irregularly ovoid, often somewhat bluntly angular from mutual pressure, the base truncate, the summit rounded, 1 side (sometimes 2 sides) flattened; the surface is smoothish, or somewhat granular-leathery, the color purple, varying to brownish or brown, a crack often indicating the margins of the cotyledons. They are rather tough-fleshy, and somewhat aromatic, bitter, and astringent.

The dried kernels are usually separated into their cotyledons, which are halves or quarters of the above described bodies, the size a little diminished by drying, which also warps them considerably and usually causes the flat surface to become concave, with sharp edges which are slightly incurved. The color is a deep-brown, the flat side commonly a little lighter, and the surface is granular-wrinkled. They are heavy, hard, and tough, the fractured surface light-brown and minutely granular. There is no odor, and they have merely a slight astringent taste. No other drug can possibly be mistaken for dried kola.

Some confusion, involving commercial complications, has arisen over the question whether the kola having more than 2 cotyledons is of the same species as the other. Schumann appears to have determined differences in the flowers which prove the seed with 2 cotyledons to be from *C. vera*, his newly described species. Both are extensively used, but the latter are preferred and bring a higher price.

Constituents.—Kola seeds contain fat, 0.1 per cent. of volatile oil, from a trace to 4 per cent. of sugar, more than 40 per cent. of starch, 1.7 to 4 per cent. of kolatannin, and 1.5 to 3.6 per cent. of total alkaloids. From $\frac{1}{100}$ to $\frac{1}{40}$ of this alkaloid is *theobromine* ($C_7H_8N_4O_2$), and the rest is *caffeine* ($C_8H_{10}N_4O_2$). The ash amounts to 3 or 4 per cent. Kilmer (1896) describes the *kolanin* of Knebel as a body which under the influence of heat or ferments splits into glucose, caffeine, and a tannin (*kola-red*). One of these ferments, *kolazyn*, he obtained from the fresh seeds. Knox and Prescott, in an exhaustive study (*Proc. Am. Pharm. Assoc.*, 1896, 1897), have shown this caffeine-bearing substance to be neither an oxidation-product nor a glucoside, but *kola-tannate of caffeine*. Their estimations indicate a much greater caffeine content (2.7 to 3.6 per

cent.) than did those of previous investigators, who had not taken cognizance of this combined alkaloid. Caesar and Loretz find the caffeine to be much diminished by roasting the seeds; and Porkin states that the germinated nuts are believed in Congo to be much stronger than those not germinated, yet Knox and Prescott found that, though sterilizing destroys the ferment and checks the formation of kola-red, it does not change the amount of caffeine obtained. Dohme and Engelhardt (1896) found 1.93 per cent. of alkaloid in Jamaica cola, and 2.24 per cent. in the African. Jean (1896) obtained the following percentages from the different sources: Congo, 1.17 to 1.48; Niger, 0.9 to 1.23; Sierra Leone, 2.27 to 2.41; Ivory Coast, 1.86; Soudan, 1.33; and East Indies, 1.63. Heckel and Schlagdenhauffen found the polycotyledonous variety (*C. acuminata*) to yield only half as much alkaloid, and twice as much fat. Topping obtained the same alkaloid yield from both the red and the white seeds. Caffeine kola-tannate represents about half the total alkaloid. It is only slightly soluble in water, but is so much more so in the presence of caffeine or tannin that it is taken up in the aqueous infusion.

Kola-tannin is a cream-colored powder, freely soluble in water, alcohol, and acetone, sparingly soluble in ether, and quite insoluble in chloroform and benzin. It turns green with ferric chloride, precipitates albumin, and belongs to the oak-tannin group, no gallotannic acid being found in kola. Boiled with dilute acids, it forms protocatechuic acid, and a red or dark-brown amorphous substance, insoluble in water, alcohol, chloroform, or ether, and only partly soluble in alkalies, so that it may be a mixture.

("It cannot be assumed that a stable caffeine compound of an acid of such marked chemical individuality as that of kola-tannin can have the same physiological effect as free caffeine, a fact of importance in considering the activity of all caffeine beverages." —Knox and Prescott.)

Valuation of Kola.—The method of Keller (somewhat modified) for the determination of the caffeine content of kola nut is simple and gives good results. Place 6 Gm. of the powdered drug in a flask or bottle and add 84 Cc. of chloroform and 6 Cc. of 10 per cent. ammonia water. Shake for half an hour and let stand for 4 hours. Pour off 70 Cc. of the chloroform solution, filtering if necessary into a tared flask, and rinse the measuring cylinder and filter with a little chloroform. Then distil off the chloroform and purify the residue by dissolving in hot water, allowing the liquid to cool, adding ammonia water and shaking out with 2 or 3 portions of chloroform, which are drawn off into a tared flask, evaporated to dryness and dried to constant weight. Instead of adding ammonia water and shaking out with chloroform, it will generally suffice to evaporate the aqueous solution to dryness. The weight of residue obtained, which latter should be free from color, when multiplied by 20 expresses the percentage of caffeine present. The following plan may also be employed: Mix 10 Gm. of powdered kola nut in a porcelain dish with 5 Gm. of calcined magnesia, and add 60 Cc. of 70 per cent. alcohol. Stir well and evaporate to dryness on a water-bath, stirring with a glass rod to guard against loss. Mix the dry residue with 30 Cc. of alcohol of the same strength as the preceding, and again evaporate to dryness. Transfer the residue to a dry bottle, add 100 Cc. of chloroform, and shake well during 1 hour. Allow the liquid to settle, and filter off 50 Cc. of the chloroform solution into a tared flask, evaporate, and dry the residue to constant weight. The weight of caffeine obtained, multiplied by 20, expresses the percentage. Treatment of the powdered drug with ammonia water, or calcined magnesia and heat, is intended to decompose the caffeine kolatannate (so-called kolanin), and thus insure complete extraction by the chloroform of all the caffeine, free and combined, present.

Pharmaceutical Preparation.—Fluidextract of Kola, which is named in the National Formulary as Fluidextract of Sterculia.

Action and Uses.—Kola may be employed for practically the same purposes as caffeine. The remedy has been recommended in the treatment of cardiac failure and in tropical diarrhœa. It is claimed that the powder when eaten increases one's power of enduring fatigue without food, and it has been employed to some extent for this purpose. It may also be given for headache, neuralgia, and migraine, and is useful in cases of nervous breakdown resulting from overwork. Its physiological effects are closely allied to those of caffeine. The dose in substance is from 20 to 40 grains (1.3–2.6 Gm.), 3 times daily.

Allied Species and Products.—The number of species in this genus is variously estimated at from 14 to 30, the higher number claimed by Schumann, in his monograph. They are all natives of Africa, though some South American plants have been erroneously classed with them. Schumann states that the seeds of *C. lepidota* Schum. with 2 cotyledons, and another species, are used similarly to the official. Flückiger speaks of a *Kola ballaya*, with 6 cotyledons, as containing 1 per cent. of caffeine. None of the several other seeds which have been sold as kola contains caffeine. The most important substitute is the African *Garcinia*

Kola Heckel (*False, Male,* or *Bitter kola;* Fam. *Guttiferæ*), which is a fruit and not a seed, and is bitter and astringent. It is not exported. The seed of *Pentadesma butyracea* Don (*Kanya*), related to the last, closely resembles kola, and is sometimes mixed with it in commerce. It contains no alkaloid, but much fat, which is extracted and used under the name *Kanya butter*. *Heritiera littoralis* Ait., of this family, widely diffused through the tropics of the Old World, is said to yield a smaller seed of a purplish-brown color, free from caffeine or kolanin. A Santa Domingo false kola has been seen in commerce, and identified as *Dimorphandra Mora* Schomb. (*Mora excelsa* Benth.—Fam. *Leguminosæ*). Several other substitutes have been occasionally reported.

COLCHICINA, *U. S.*—Colchicine.

Colchicine, Fr.; *Colchicin*, G.

Formula, $C_{22}H_{25}NO_6$ or $C_{15}H_9.(OCH_3)_3.NHCOCH_3.COOCH_3$. Molecular weight, 396.23.

An alkaloid obtained from colchicum. It should be kept in dark, amber-colored, well-stoppered vials.—U. S.

Colchicine was discovered in 1820 by Pelletier and Caventou, but considered by them identical with veratrine. Although Geiger and Hesse in 1833 recognized the distinctive character of the alkaloid and applied to it its present name, its true chemical nature was not definitely determined until 1888 by Zeisel.

Preparation.—Pure colchicine may be prepared by the following process, which is based upon the fact that it is capable of forming a crystalline compound with chloroform. Colchicum seed are exhausted with hot 90 per cent. alcohol, the alcohol recovered by distillation, the residue treated with water equal in quantity to $\frac{1}{5}$ of the weight of the drug used, and filtered for the removal of resin, wax, and fatty matter. The clear dark-brown filtrate is well shaken with four successive portions of chloroform, which are united and distilled, the residue being again dissolved in water and shaken with chloroform. From the latter solution crude colchicine-chloroform separates upon evaporation of the solvent and is dissolved in alcohol, the solution being again concentrated by distillation. A third treatment with chloroform yields a yellow solution, which is evaporated on a water-bath and the residue treated with luke-warm ether and set aside, when pure colchicine-chloroform, having the composition $C_{22}H_{25}NO_6.2CHCl_3$, will separate in the form of faintly yellowish needle-shaped crystals, which are decomposed in the presence of water when heated to 100° C. (212° F.), the chloroform escaping and leaving pure colchicine in aqueous solution, from which it may be obtained as an amorphous mass by evaporation to dryness or in form of lamellæ by spreading the concentrated solution on plates of glass and drying.

Properties and Tests.—Colchicine occurs as pale-yellow leaflets, or a pale-yellow amorphous powder, turning darker on exposure to light, having an odor suggesting damp hay, and a very bitter taste. It is soluble at 25° C. (77° F.) in 22 parts of water, 155 parts of ether and in 87 parts of benzin; soluble in 26 parts of water at 80° C. (176° F.); very soluble in alcohol and chloroform; insoluble in petroleum benzin. After drying over sulphuric acid it melts if heated to 142.5° C. (288.5° F.) (143°–147° C., Bruehl), and upon incineration leaves no residue. Its aqueous solution is neutral to litmus-paper, lævogyrate, and of a yellow color, which is intensified by mineral acids. Sulphuric acid produces with colchicine a citron-yellow color, which upon addition of a drop of nitric acid changes to greenish blue, then to red, and finally to yellow. On adding an excess of potassium hydroxide, the color is changed to red. Ferric chloride test-solution, on being added to an aqueous solution of colchicine, gives no color, but on heating, a brownish-red color is developed, which changes to brownish black; if ferric chloride test-solution be added to an alcoholic solution of colchicine, a garnet-red color is at once produced. Sulphuric acid, containing a fragment of potassium dichromate, gives a greenish-blue color, changing to orange. If a mixture of 5 drops each of an aqueous solution of colchicine, fuming nitric acid, and ferric chloride test-solution be heated to boiling, a yellow solution will be formed, changing to olive green. When cool, if the liquid be shaken with a little chloroform, the latter will turn ruby red, and the aqueous layer will remain green.—U. S. Nitric acid of 1.40 specific gravity forms a violet-red colored solution with colchicine, which changes to yellow, and after dilution with water and addition of an excess of sodium hydroxide, to red. Colchicine is precipitated from acid solution by cadmium iodide, phosphotungstic acid, phosphomolybdic acid, and Mayer's Solution, but not by picric acid or platinic chloride. It yields, however, well-defined

crystals as a double chloride with gold chloride, if the latter be added in excess to a solution of the alkaloid slightly acidified with hydrochloric acid.

The salts of colchicine are not very stable. The one most used is the salicylate, $C_{22}H_{25}NO_6.HC_7H_5O_3$, made by moistening a mixture of 20 parts of colchicine and 7 parts of salicylic acid with water and subsequently drying the same. It is a yellow amorphous powder, soluble in water and alcohol. The name *colchisal* has been given to a solution of colchicine in methyl salicylate, dispensed in gelatin capsules, each containing 0.00025 Gm. of the alkaloid and 0.2 Gm. of the methyl ester.

Action and Uses.—Colchicine and its salts may be used in those conditions in which colchicum is indicated. As a substitute for colchicum it has not met with the full approval of the medical profession, and it probably does not represent fully the medicinal properties of the seed or root. The dose is from $\frac{1}{160}$ to $\frac{1}{120}$ grain (0.0004–0.0005 Gm.).

COLCHICUM, *U. S.*—Colchicum.

Meadow-saffron, E.; *Herbstzeitlose, Wiesensafran*, G.; *Colchique, Safran Bâtard, Veillotte, Veileuse*, Fr.; *Colchico*, It., Sp.

Official Parts.—1. Colchici Cormus, U. S., Br.—The dried corm of *Colchicum autumnale* L. (Fam. *Liliaceæ*), yielding not less than 0.35 per cent. of colchicine.

2. Colchici Semen, U. S., *Colchici Semina*, Br.; *Semen Colchici*, P. G.—The dried ripe seed of *Colchicum autumnale* L., yielding not less than 0.55 per cent. of colchicine.

Either the seeds or the corm, or both, are official in all pharmacopœias. The British requires that the corm be dried at a temperature not exceeding 65.5° C., the Italian that it contain from 0.08 to 0.2 per cent. of colchicine, and that the seeds contain 0.2 to 0.4 per cent. The Portuguese prohibits the substitution of the seeds of other species of *C.*, and several pharmacopœias exclude seeds of a pale or yellowish color, and those that have been kept more than a year.

Origin.—A rather handsome low herb of pastures and meadows of central and southern Europe. In its late fall-flowering it might be regarded, physiologically, as a precocious spring plant, since its seeds are not ripened until the following summer. In the autumn, the subterranean portion consists of the fully developed corm, bearing at its apex the scar left by the fruit-stem of the preceding summer. A tuft of root-fibers is attached to a lateral projection of the base, above which there is a shallow groove running to the apex of the corm. In the lower part is a conical rudimentary stem with 3 or 4 rudimentary leaves, and bearing upon the apex 1 or more flowers, with the lower part of their long perianth-tubes resting in the groove. The whole is surrounded by a few brown leaves, forming a sheath above. After flowering, the tuber gradually diminishes in size, until by the following summer it is completely absorbed and decayed. In the meantime the upper internode of the short conical axis is gradually developed into a stem rising above ground with the capsules, and at the base is enlarged to an ovoid fleshy corm, as yet without the lateral groove, but showing in the lower axil the bud, which by the following autumn will be developed into a short conical flowering axis, while in the meantime the lateral groove on the fruit-bearing tuber will have been formed. The development and duration of the tuber embrace, accordingly, a period of 2 years, in the first half of which the tuber produces flowers and fruit, and afterward serves for developing and nourishing its successor. The tubers are collected in July and August, before the appearance of the flowers; but Schroff (1856), and afterward Maclagan, concluded from physiological experiments that the proper time for its collection is the period of flowering or immediately afterward.

Description.—The Corm.—About 2.5 Cm. (1 In.) long and two-thirds as broad, ovoid-conical, somewhat laterally compressed, with a large longitudinal groove upon the flatter side, or in reniform transverse or ovate longitudinal slices of the same; externally gray-brown or brownish-gray, finely wrinkled; internally whitish, solid, the dried transverse surfaces presenting a papillose appearance; fracture short, starchy; odorless and of a sweetish and bitter, afterward somewhat acrid taste.

The powder is of a light-gray or slightly brownish-gray color. Its abundant starch-grains are mostly compound or angular, nearly isodiametric and the nearly central hilum strongly stellate.

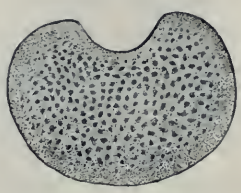
The Seeds.—About 2.5 Mm. ($\frac{1}{10}$ In.) in diameter, globoidal, with a slight point at the hilum; reddish-brown; finely pitted; internally whitish; tough and of bony hardness; odorless and of a bitterish and somewhat acrid taste. They are well distinguished from all similar seeds by their hardness.

Constituents.—Besides resin and fatty matter, colchicum contains as its most important constituent the alkaloid colchicine (treated separately elsewhere), and of which about 0.4 per cent. is found in the root, and from 0.4 to 0.6 per cent. in the seed. Colchiceine, $C_{21}H_{23}NO_6 + \frac{1}{2}H_2O$, which was at one time supposed to exist in colchicum, is

FIG. 130.

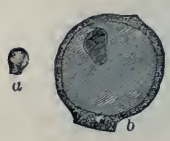
Tuber of colchicum.

FIG. 131.



Colchicum: transverse section.

FIG. 132.



Colchicum seed: *a*, natural size; *b*, section magnified.

produced, according to Zeisel, as a result of hydrolysis by extracting the drug with acid menstrua. Chemically it may be looked upon as acetyl-trimethyl-colchicic acid; but according to Bruehl, it gives no reaction with litmus-paper and seems to form compounds with mineral acids. It is said to be non-toxic and occurs in white crystals, which are inodorous and soluble in hot water, alcohol, and chloroform, but only slightly soluble in cold water. It readily dissolves with yellow color in solutions of the alkalies and their carbonates. Colchiceine ordinarily melts at 140° C. (248° F.), and in the anhydrous condition at 172° C. (341.6° F.). By treatment with mineral acids it is split up into acetic acid, methyl alcohol and apocolchiceine. It is readily converted into colchicine by etherification with methyl alcohol and hydrochloric acid, or by treatment with methyl iodide and sodium hydroxide in methyl alcohol. Colchiceine was first obtained in 1856 by Oberlin.

The Pharmacopœia requires that the corm and seed of colchicum, when assayed by the process officially given, which is practically identical with that given below, shall yield respectively not less than 0.35 per cent., and 0.55 per cent. of colchicine. Another method and perhaps better than the official, for the valuation of colchicum, is that of Gordin and Prescott, published in the *Proc. Am. Pharm. Assoc.*, 1900, page 133.

Assay of Colchicum Corm or Seed.—Colchicum corm (or seed), in No. 60 powder, 10 Gm.; ether, chloroform, alcohol, ammonia-water, distilled water, each a sufficient quantity. Introduce the colchicum corm (or seed) into a 200 Cc. Erlenmeyer flask, and add to it 100 Cc. of a mixture of 77 Cc. of ether, 25 Cc. of chloroform, 8 Cc. of alcohol, and 3 Cc. of ammonia-water, insert the stopper securely, and macerate with frequent shaking for 12 hours (or preferably for 4 hours in a mechanical shaker). Filter a sufficient quantity of the liquid into a measuring cylinder until 50 Cc. (representing 5 Gm. of colchicum corm or seed) have been obtained; then transfer it to a beaker or dish, and evaporate it nearly to dryness by applying a very gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether has evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in the beaker or dish. Redissolve the residue in a little ether, add 5 Cc. of water, and proceed as before. Wash the container and filter with a little water, and shake the aqueous solution well for a minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a tared flask, and again shake out the aqueous liquid with 3 portions of 10 Cc. each of chloroform, collecting these solutions in the tared flask. Evaporate the chloroform completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve the residue in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.) until the weight remains constant after cooling. The weight of the residue multiplied by 20 gives the percentage of colchicine in the corm (or seed).—U. S.

Pharmaceutical Preparations.—EXTRACT OF COLCHICUM CORM, U. S. P.; FLUIDEXTRACT OF COLCHICUM SEED, U. S. P.; TINCTURE OF COLCHICUM SEED, U. S. P.; WINE OF COLCHICUM SEED, U. S. P.

Action and Uses.—When colchicum is taken in overdose, it produces violent gastro-enteritis, and if the dose be large, death inevitably results because of the violent inflammation of the gastro-intestinal tract and of the kidneys which ensues. When moderately large doses are taken for several days, heat and discomfort are often felt in the epigastrium, and some laxity of the bowels and even nausea and vomiting may

develop. The drug is one of the most dangerous of poisons, because after it is taken in large doses nothing can be done for the cure of the patient provided it has remained long enough in the stomach to produce its inflammatory effects. Colchicum is not so largely employed in the United States as it is in England, as cases of true gout are not so frequently met with in America as in the British Isles. It is in true gout alone that colchicum finds its chief medicinal value, and practitioners of experience are generally in accord that if it is given in as large dose as the patient will bear, it does more to cut short an attack of acute gout than any other remedy. In the aberrant form of gout with lithæmia it does not possess the same specific influence. In the treatment of gout, the wine of the root is most commonly employed in the dose of from 10 to 30 minims (0.60–2 Cc.), repeated every few hours until evidences of gastric irritation or pain in the bowels develops. The drug has been used in the treatment of acute and chronic rheumatism, but is probably of little value in those affections. The active principle of colchicum has been largely employed in the last few years to substitute the wine of the root. It is given dissolved in oil of gaultheria in capsules, or it may be given in pill-form. It is a powerful poison. Its dose varies from $\frac{1}{150}$ to $\frac{1}{100}$ grain (0.0004–0.0005 Gm.), 3 or 4 times a day.

Other Species.—The genus contains some 30 species, a number of which have been similarly employed. The Oriental *Hermodactyls* are supposssd to have been derived from *C. variegatum* L., *C. speciosum* Stev. (*C. Illyricum* Friw.), and *C. luteum* Baker.

COLLODIUM, *U. S., Br., P. G.*—Collodion.

Collodion, Fr.; *Collodium, Kollodium*, G.; *Collodio*, It.

Preparation.—Pyroxylin, 40 Gm.; ether, 750 Cc.; alcohol, 250 Cc. To the pyroxylin, contained in a bottle, add the ether, and let it stand for 15 minutes; then add the alcohol, and shake the mixture until the pyroxylin is dissolved. Cork the bottle well and set it aside until the liquid has become clear. Then decant it from any sediment which may have formed, and transfer it to bottles which should be securely corked. Keep the collodion in a cool place, remote from lights or fire.—U. S.

Collodion prepared from 295 grains of pyroxylin, 12 fluidounces of ether, and 4 fluidounces of alcohol, will correspond to the official article.

The British Pharmacopœia directs the solution of 1 ounce of pyroxylin in a mixture of 36 fluidounces of ether and 12 fluidounces of 90 per cent. alcohol. The proportions of the German Pharmacopœia are: 1 part of collodion-cotton to 21 parts of ether and 3 parts of alcohol. The pharmacopœias order the solution to be poured off from any sediment which may form.

Properties.—If the pyroxylin—or, more correctly, *colloxylin*—has been properly made, there is no difficulty in preparing collodion by simply agitating it occasionally with the liquid. It forms a neutral, nearly clear or slightly opalescent, either colorless or slightly yellowish, liquid having a syrupy consistence and ethereal odor. On evaporation it forms a colorless, glossy, and contractile film.

Pharmaceutical Uses.—Collodion and flexible collodion may be used as an excellent vehicle for the local application of medicinal substances soluble in ether, such as aconitine, atropine, tannin, salicylic acid, iodine, iodoform, resorcin, pyrogallol, carbolic acid, oleoresin of capsicum, camphor, corrosive sublimate, red mercuric iodide, etc.

Collodions are best dispensed in small round-shouldered vials provided with a cork through which a camel's-hair pencil has been passed and securely fastened; this avoids loss of material and drying of the collodion in the brush—a very annoying occurrence.

Medical Uses.—Collodion is employed as a protection to cuts, wounds, and abrasions. Because it contracts upon drying, it frequently causes considerable pain, and unless required to coapt the edges of a wound, the flexible collodion should be substituted for it. It is painted over small boils and buboes for the purpose of causing their absorption, and is said to be more or less successful in the treatment of acne, herpes zoster, and intertrigo.

COLLODIUM CANTHARIDATUM, *U. S., P. G.*—Cantharidal Collodion.

Collodium vesicans, Br.; *Collodium cantharidale.—Blistering collodion*, E.; *Collodion vésicant (s. cantharidé, cantharidal)*, Fr.; *Blasenziehendes Kollodium, Spānisch-fliegen-Kollodium*, G.

Preparation.—Cantharides, in No. 60 powder, 60 Gm.; flexible collodion, 85 Gm.; chloroform, a sufficient quantity. Pack the cantharides firmly in a cylindrical percolator,

and gradually pour chloroform upon them until the cantharides are exhausted. Recover the chloroform by distillation on a water-bath, and evaporate the residue in a capsule, by means of a water-bath, until it weighs 15 Gm. Dissolve this in the flexible collodion, and let it stand at rest for 48 hours. Finally, pour off the clear portion from any sediment which may have been deposited and transfer it to bottles, which should be securely corked. Cantharidal collodion should be kept in a cool place, remote from lights or fire.—U. S.

If 4 avoirdupois ounces of cantharides be exhausted with chloroform, the resulting tincture evaporated (as directed above) to 1 avoirdupois ounce, and sufficient flexible collodion then added to make the mixture weigh 6½ avoirdupois ounces, the finished product will be about of pharmacopœial strength.

Chloroform is an excellent solvent for cantharidin or the cantharidin compound contained in old Spanish flies. Powdered cantharides being much lighter than chloroform, their percolation with this menstruum presents some difficulty unless pressed down by a layer of washed sand. Owing to the volatility of the chloroform, percolation should be performed with an apparatus such as is used for the percolation of ethereal liquids (see OLEORESINÆ), and the greater part of the menstruum remaining absorbed in the powder may be recovered by judicious percolation with water. The present formula is similar to that of Procter (1852), in which, however, ether was used for exhausting the cantharides; the inflammability of this liquid and its vapor requires additional precautions in distilling the tincture.

Blistering Collodion of the Br. P. (*Collodium vesicans*) is slightly weaker than the above, and does not form a flexible film. It is prepared by dissolving ½ avoirdupois ounce of pyroxylin in 1 Imperial pint (20 fluidounces) of Blistering Liquid, which latter represents 50 Gm. of cantharides in 100 Cc. of finished product, and is made with acetic ether.

The German Pharmacopœia directs this preparation to be made by exhausting coarsely powdered cantharides with a sufficient quantity of ether, evaporating the tincture to a syrupy consistence, and adding sufficient collodion (not flexible) to make the total weight of the finished product equal the weight of the cantharides used.

Properties.—Cantharidal collodion has the same physical properties as flexible collodion, except that it is of a brownish-green color, which becomes yellowish on exposure to light; it is therefore best kept in amber-colored vials. The film left on evaporation has also a greenish color.

Action and Uses.—The medicinal properties of cantharidal collodion have been described under Cantharides (which see). It has an advantage over the cerate in that it can be applied more readily and it is more cleanly. It should be applied with a camel's-hair brush.

COLLODIUM FLEXILE, *U. S.*, *Br.*—Flexible Collodion.

Collodium elasticum, P. G.—*Collodion élastique*, Fr.; *Elastisches Kollodium*, G.

Preparation.—Collodion, 920 Gm.; Canada turpentine, 50 Gm.; castor oil, 30 Gm.; to make 1000 Gm. Mix them and keep the mixture in a well-corked bottle in a cool place, remote from lights or fire.—U. S.

This is nearly identical with the formula of the British Pharmacopœia: the German Pharmacopœia directs the dissolving of 1 part of castor oil and 5 parts of turpentine in 94 parts of collodion.

Flexible collodion may also be made by weighing successively, into a tared bottle, 4 avoirdupois ounces of collodion, 95 grains of Canada turpentine, and 57 grains of castor oil.

Properties.—This preparation has the same appearance as collodion, but on evaporation it forms an elastic and scarcely contractile film.

Medical Uses.—Flexible collodion is used as a protection where an air-tight dressing is needed. It is employed quite largely as a vehicle for iodine, iodoform, caustic and astringent remedies. Its application is said to prevent the pitting of smallpox.

The following medicated varieties of flexible collodion are recognized in the National Formulary:

Compound Salicylated Collodion.—Made by dissolving extract of Indian hemp 2 Gm. in alcohol 10 Gm., mixing this with a solution of salicylic acid 11 Gm. in flexible collodion 50 Gm., and finally adding sufficient flexible collodion to make the total weight 100 Gm.

Croton Oil Collodion.—Made by mixing croton oil 10 Gm. with flexible collodion 90 Gm.

Iodized Collodion.—Made by dissolving iodine 5 Gm. in flexible collodion 95 Gm.

Iodoform Collodion.—Made by dissolving iodoform 5 Gm. in flexible collodion 95 Gm.

COLLODIUM STYPTICUM, *U. S.*—Styptic Collodion.

Collodium hæmostaticum.—Styptic colloid, Xylostyptic ether, E.; *Collodion au tannin, Collodion styptique,* Fr.; *Tannin-Kollodium,* G.

Preparation.—Tannic acid, 20 Gm.; alcohol, 5 Cc.; ether, 25 Cc.; collodion, a sufficient quantity to make 100 Cc. Introduce the tannic acid, alcohol, and ether into a graduated bottle, agitate until the tannic acid is thoroughly incorporated and partially dissolved, then add sufficient collodion to make up the volume to 100 Cc., and shake occasionally until the acid is completely dissolved. Keep the product in cork-stoppered bottles, in a cool place, remote from lights and fire.—U. S.

Styptic collodion of pharmacopœial strength may also be prepared by using 620 grains of tannic acid, 160 minims of alcohol, 13½ fluidrachms of ether, and sufficient collodion to bring the volume up to 6¾ fluidounces.

Owing to the large proportion of tannin ordered in the formula for styptic collodion, it is necessary to use a small quantity of diluent—ether and alcohol—with which the tannin is thoroughly mixed before the final addition of collodion. Flexible collodion is not suitable in this case, as a constringent pellicle is desired. Any impurities from the tannin may be removed by rapidly straining the solution through gauze previously moistened with ether and alcohol.

This preparation was suggested originally by Dr. Benjamin W. Richardson (1867), who added a small quantity of tincture of benzoin. A somewhat similar but much stronger preparation is the one recommended by Pavesi, consisting of tannin 5 parts, carbolic acid 10 parts, benzoic acid 3 parts, and collodion 100 parts.

Medical Uses.—Styptic collodion was introduced as an astringent and local hæmostatic agent, but experience has proved it to be of very little value.

COLOCYNTHIS, *U. S.*—Colocynth.

Colocynthidis Pulpa, Br.; *Fructus Colocynthidis,* P. G.; *Poma colocynthidis.—Bitter apple, gourd,* or *cucumber,* E.; *Koloquinthen,* G.; *Coloquinte,* Fr.; *Colloquintide,* It.; *Coloquintid,* Sp., Port.

The peeled dried fruit of *Citrullus Colocynthis* Schrader (Fam. *Cucurbitaceæ*). Colocynth is gathered when full-grown, but still immature, dried, and deprived of its rind, the seeds to be rejected before using.

Colocynth is official in all pharmacopœias, some of which name the pulp in the title, and specify that ether should extract from it only traces of fixed oil. The Br. P. guards against ground colocynth which contains the seeds, by requiring at least 9 per cent. of ash.

Origin.—A perennial, hispid, tendril-bearing herb with yellow monœcious flowers, resembling the watermelon plant, inhabiting hot, arid, sandy regions of the Mediterranean basin, and introduced thence through southern Asia and eastern Africa. It is gathered just before maturity, dried in the sun, and peeled. Efforts to cultivate it in England have not been successful. In Texas it produced large fruits, but they were deficient in active constituent. The supply of wild colocynth is inexhaustible. From the rinds is prepared a blackish, resinous, bitter and nauseous extract, which is spread upon water-bags to repel camels. Colocynth seeds contain about 17 per cent. of fat, and after very thorough cleaning are sometimes used as food by the natives.

FIG. 133.

Peeled colocynth · longitudinal and transverse sections.

Description.—Globular, from 5 to 10 Cm. (2 to 4 In.) in diameter, the pulp white or whitish, very light, spongy, readily separable longitudinally into 3 carpels, each with numerous flat, ovate, white or light-brown seeds, mostly near the outer and convex surface; odorless and of an intensely bitter taste. No starch is present, and the ash of the pulp should not exceed 12 per cent. nor be less than 9 per cent. The ash of the unripe seeds equals only about 2.5 per cent., that of the ripe seeds about 4.5 per cent.

The preceding is a description of Trieste or Turkish colocynth.

The Spanish article is usually smaller, has a great many black or blackish seeds, with a correspondingly much smaller proportion of pulp, and this is more compact and darker. The pulp should constitute from 30 to 35 per cent. of the total weight. Lots of unpeeled fruit are occasionally seen, as well as a Syrian variety, which is very greatly shrivelled, due to its having been peeled before drying. In purchasing colocynth, the pharmacist should guard against receiving an undue proportion of seeds, which fall out and accumulate to a great extent in the last portions in the box or barrel.

Constituents.—The unimportant constituents of colocynth pulp are pectin, gum, a trace of fixed oil, and calcium and magnesium phosphates. *Colocynthin* ($C_{56}H_{84}O_{23}$), usually amorphous, but crystallizable, is a pale-yellow inflammable powder, soluble in 8 parts of water, more so in alcohol and ammonia water, and almost insoluble in ether and chloroform. By treatment with acids it yields sugar and resinous *colocynthein*. Colocynthin constitutes 2 per cent. of the pulp (Wagner, 1893). *Colocynthitin* occurs in tasteless white microscopic prisms, insoluble in water and cold absolute alcohol, but soluble in ether and boiling alcohol. It is probably a resin. The ash from the pulp amounts to from 9 to 14 per cent., from the seeds, 2 to 4 per cent., and from the whole fruit, only 4 to 5 per cent. The seeds contain practically no colocynthin. In India their fixed oil is extracted for use.

Pharmaceutical Preparations.—Extract of Colocynth, U. S. P.; Compound Extract of Colocynth, U. S. P.; Compound Pills of Colocynth, N. F.; Pills of Colocynth and Hyoscyamus, N. F.; Pills of Colocynth and Podophyllum, N. F.

Action and Uses.—Colocynth belongs to that class of drugs known as hydragogue cathartics, since it produces large watery stools when taken in full medicinal dose. For this reason colocynth has been largely employed by many practitioners for the relief of cardiac and renal dropsy. The contraindication to its employment in these cases is any condition of circulatory or respiratory feebleness, since the active purging may unduly weaken the patient. Overdoses of the drug, as might be supposed, produce violent gastro-enteritis, and death may be caused by the inflammation of the stomach and bowels associated with exhaustion produced by excessive purging and vomiting. Small quantities of colocynth are sometimes added to purgative pills in cases of obstinate constipation to increase their efficacy. Colocynth is rarely employed alone. It is most commonly used in the form of the Compound Extract of Colocynth (which see).

If colocynth is employed as a purgative, to produce large watery stools, it is commonly given in the dose of from 5 to 10 grains (0.30–0.60 Gm.). As a powerful laxative it may be given in the dose of from 2 to 5 grains (0.12–0.30 Gm.). The purgative dose may be repeated at the end of 8 or 12 hours if the first one has not produced satisfactory results.

COMBRETACEÆ.—The Myrobalans Family.

A family of 15 genera and nearly 200 species. The fruits of *Buceras*, P. Br. (*Terminalia*, L.) are considered in connection with Galla. The barks of many of those species also are astringent. *B. fagifolia* (Mart.) (*Terminalia f.* Mart.), of Brazil, yields a drastic resin, and the root of *B. macroptera* (Guill. et Per.) (*Terminalia m.* G. et P.), the *Rebreb* of Senegal, has similar properties.

Several species of *Conocarpus* L., especially *C. erecta* Jacq., the Zaragosa mangrove, have local uses, as has the bark of *Laguncularia racemosa* (L.) Gærtn. (*Conocarpus r.* L.), the *Manca Branca* of the West Indies. The fruit and leaves of *Quisqualis Indica* Lour. are used in India under the names *Rangun kibel*, *Irangun mali*, etc. The seed-kernel tastes like Cacao, but is powerfully anthelmintic. Large doses produce hiccoughing. Its greenish fixed oil is supposed to be the active agent. In China, *Q. Chinensis* (*Sze-kiun-tsze*) is used similarly.

The genus *Combretum* L., containing upward of 125 species of tropical regions, yields a number of very active barks, leaves, and fruits. Several of these are used, and apparently possess some special activity, in the treatment of gall fever and various specific tropical fevers. This is especially true of the leaves of *C. altum* G. et P. and of *C. Raimbaultii* Heck., both known as *Kinkeliba* in Africa. The leaves of *C. racemosum* Beauv., also of Africa, are anthelmintic. An African arrow poison is believed to come from the astringent bark of *C. grandiflorum* Don., and the genus is credited with yielding other arrow poisons. The fruits of *C. decandrum* Roxb. (*Umtandawa*) and *C. erythrophyllum* Sond. (*Umbida*), of South Africa, are strongly poisonous.

COMPOSITÆ.—The Daisy Family.

As here regarded, including as subfamilies several groups regarded by some botanists as distinct families, the *Compositæ* is much the largest of all the families of plants. It comprises more than 800 genera and more than 10,000 known species, a number which is likely to be at length increased by at least a half.

By most botanists the *Compositæ* are placed at the head of the vegetable kingdom, as representing its highest degree of development, although this distinction is contested by the *Leguminosæ*. These plants are distributed over the entire globe. They are mostly herbs, though a great many shrubs and a few trees are included.

Owing to the very peculiar structure of this family of plants, a number of distinct descriptive terms, not applied in other families, have to be employed. The following synopsis of structure and terminology will therefore be found useful. The system and methods of arrangement of the flowers are not less important as family characteristics, and as a basis of classification, than is the floral structure. A number of flowers, usually many (very rarely reduced to one), are massed closely together in a *head*, surrounded and clasped by a number of modified leaves, the *bracts*, together constituting the *involucre*. This involucre may be *double*, sharp differences existing between its outer and inner portions, or the changes may proceed gradually from the outer to the inner bracts. The involucre, or each of its divisions, consists of from one to very many series or cycles of bracts. If of one, they appear in a circle; if of more, the arrangement is more or less spiral. The scales may be quite distinct or a portion or all of them may cohere at the base or for any part or the whole of their length. In all these respects, in its form and relative position or that of its parts, the number of its series, or even of the scales, and the individual characters of the latter, even to minute details, the characters of the involucre, are constant and characteristic. The more or less expanded termination of the stem, enclosed by the involucre, is the *receptacle*, the characteristics of which are not less important than those of the involucre itself. These include its form, in a few cases its structure or consistency, and especially its surface and the appendages upon the latter. It is rarely entirely smooth. It frequently exhibits prominent pits, like the cells of a honeycomb, when it is said to be *foveolate*. The margins of these pits may be unaltered or elevated, entire, notched, or variously fringed. The intervening portions may be naked or more or less densely clothed with scales (paleæ or chaff), hairs, or bristles. When such scales exist, their own characteristics are of the utmost importance. They may be flat, or each variously folded or wrapped about a flower, and they occasionally adhere and even enlarge as prominent portions of the fruit. Their form, apex, margin, appendages, and consistency are wonderfully various. The individual flowers of the head are, of course, relatively very small, in many cases minute, and are commonly spoken of as *florets*. They may be hermaphrodite (either fertile or sterile), monœcious, diœcious, or polygamous. If pistillate, they may be fertile or sterile. Occasionally, those of the same head, possessing similar sexual organs, will be partly fertile and partly sterile. A head in which all the florets agree in these respects is called *homogamous;* one which exhibits differences therein is *heterogamous*. The calyx is always present as to its tube, though this is not apparent, being adherent to the outer surface of the ovary. The limb of the calyx may be present or obsolete. In the original type of the family it was tubular and 5-toothed, but this condition is not now seen, except imperfectly in a few cases. So profound have been the changes of development that it has ceased to be called a calyx, and is known as the *pappus*. When only its last vestiges exist, it is seen as a mere circular rim upon the summit of the ovary. When a little less reduced, this rim is a ring, cup, or tube, its margin from very slightly to strongly lobed or toothed, or with the teeth extended into scales (*paleæ*), slender spines (*awns*), or awns with a paleaceous base, or into bristles (*setæ*) or hairs. These structures may be 5 in number, corresponding to the original sepals, or reduced even to one, and they may be equal and similar or unequal or dissimilar. Similar or different parts may be alternated with the former, or each sepal may have become divided into from 2 to a great number of bristles, these coherent at the base into groups, each representing a sepal or a part of one, all equally so coherent or entirely separate. In many cases, the outer members will be shorter or otherwise different from the inner, thus constituting a double pappus. The individual paleæ, awns, setæ, or hairs are as greatly varied as any individual organ of any other flower. Awns are frequently hooked at the end, or barbed. Setæ or hairs are commonly toothed along the margins (*serrate*), and these teeth may be extended into branch-setæ or -hairs (the *plumose* bristle). They may be tapering, acute, or upwardly thickened; or the plumose condition may be present at the tip only (the *pennicillate* or *tufted* bristle). The original typical corolla of the family was tubular and 5-toothed, like the calyx, and a great majority of the species still retain this condition for at least a part of their flowers. Variations in such tubular corollas are, of course, as common and important as when they occur in other families. A more profound modification is the development of the *ligulate* or strap-shaped corolla. This may have been developed in all cases from the same direction, or two different

lines may have been followed in two branches of the family. One known method has been the development of the 2-lipped (*bilabiate*) condition, in which 1 lip, the outer or lower, was, and in many cases has remained, 3-lobed, the upper or inner 2-lobed or 2-toothed. This upper lip is that which has suffered the greatest change. It has been reduced until in some genera we find only a long thread-shaped filament, or a small tooth or ligule, of it remaining, and in a great many cases it has disappeared altogether. In such cases, we have at the base a more or less short tubular portion, passing above by an oblique orifice into a more or less elongated flat or strap-shaped, normally 3-toothed body, the ligulate corolla. The fact that this ligulate corolla exhibits in some cases a 5-toothed summit seems to indicate that in such cases the condition has been attained by a simple fissuring of the inner or upper side of the tube and the flattening out of the split portion. The relative occurrence and position of ligulate or bilabiate and of the ordinary tubular florets is of fundamental importance in the classification of this family. In the great subfamily *Cichoriaceæ*, all the florets of the head are ligulate. In the remainder of the family all or a part are tubular, together forming the *disk*. When, in the latter class (the *Discoideæ*, such heads being called *discoid*), ligulate or bilabiate flowers occur, they form one or more marginal circles, such as the white portion of a common daisy, and constitute the *rays*, the head being then called *radiate*, otherwise *eradiate*. Under cultivation, the disk-flowers often become replaced by the gradual invasion of the rays, until all or most are radiate, the *double* condition of the dahlia, chrysanthemum, aster, etc. When disk and rays are colored similarly, the head is *homochromous;* when differently, *heterochromous*. The stamens are 5 in number, their filaments separate and adnate to the corolla, at least to the base, the anthers, with rare exceptions, other than in the *Ambrosiaceæ*, where they are separate, cohere by their edges into a ring or, being elongated, into a tube. The anther-bases are frequently elongated into short or sometimes very long appendages, which may be either stiff or flaccid, and interesting and sometimes beautiful appendages are often borne upon the summit. The style is single, usually 2-toothed or cleft at the summit, the branches wonderfully varied in many ways, naked or appendaged at the tips and furnishing the most valuable characters for classification. The fruit is an akene—that of each floret usually separating individually, though occasionally they are enclosed together within a persistent involucre. These akenes exhibit an infinity of variation as to size, form, surface, and appendages, furnishing yet other valuable classification-characters. The seed is exalbuminous.

The chemical characteristics of the *Compositæ* are of great interest. Starch is practically wanting, being replaced by the peculiar related substance Inulin (which see), which occurs commonly only in this and in the closely related family *Campanulaceæ*. One of the most constant characters is the storage in the embryo of large amounts of fixed oils, a number of which (see *Helianthus*, etc.) are important articles of commerce. Others are likely to be introduced. Glucose is a common constituent, though rarely occurring in large amounts, and glucosides occur frequently. These glucosides are usually bitter, and are to a large extent responsible for the medicinal properties, which are in other cases to be credited to amaroids. The occurrence of alkaloids is a rare exception, and it is only recently that their presence in the family has become known with certainty. It appears, likely, however, that several of them are highly active and may become of importance in materia medica. Perhaps not second in importance to the bitter principles are the volatile oils, which constitute the most constant and abundant class of constituents of the vegetative parts. These impart to a large number of the drugs their most important activities, some of them being very powerful. Almost equally important with the volatile oils are the resins, which are not only abundant, but varied in their physical, chemical, and physiological characters, many of them powerfully active. Finally, reference may be made to the tannins, which are common and fairly abundant, and in a few instances impart the characteristic properties to the drugs. Although little studied, the tannins of this family appear to present quite a high degree of variation in their chemical properties.

The economic importance of the family is not so great as its extent would lead us to expect. It is highly ornamental, many of the members, like the asters, chrysanthemums, dahlias, sunflowers, coreopses, etc., being among the most highly prized of cultivated flowers. Comparatively few edible products are yielded, and none of these can be said to take first rank among food-plants. The best known of them are the salsify or oyster plant, the burdock root, as used in Japan, and the Jerusalem and globe artichokes. The common thistles and many others are decidedly nutritious and possess local uses as foods in various regions. In all these cases the inulin is the most important nutrient. The seeds of many species are more or less consumed as fatty products, either by the human race or by domestic animals.

In considering the drugs of the *Compositæ*, our classification is in accord with the more important active constituents, corresponding, in a general way, with their medicinal uses.

(See also LAPPA, TARAXACUM, PYRETHRUM, INULA, EUPATORIUM, TANACETUM, ABSINTHIUM, ERIGERON, SANTONINUM, ARNICA, CALENDULA, etc.)

DRUGS YIELDING FIXED OILS.

The several fixed oils, the sources of which are here described, will be found discussed in the general article on OLEA PINGUIA.

HELIANTHUS (*Sunflower, Sonnenblume*, G. ; *Helianthe, Grand Soleil*, Fr. ; *Elianto*, Sp.) is *Helianthus annus* L., a tall and coarse herb, native of tropical America and well known in cultivation in a large number of varieties. Its akenes are obovate-oblong, somewhat quadrangular, flattened, vary in color between whitish and black or are striped, and crowned with a very deciduous pappus of 2 chaffy scales. They contain from 16 to 28 per cent. of a fixed oil, on account of which they are considerably used as food for domestic animals and to some extent by human beings. They are also occasionally employed, like flaxseed, in poultices and indefinitely as a medicine. The expressed oil is an important article of commerce, being used as a cheap substitute for olive and other oils. The herbage is occasionally used for poultices and internally as a diuretic.

SILYBUM OIL is very similar, and is obtained from *Mariana Mariana* (L.) Hill (*Carduus M.* L.; *Silybum M.* Gærtn.), the *Milk-, Lady's-*, or *Virgin-Mary's-thistle, Steckkoerner, Frauendistel, Chardon Marie*. The fruit, on account of this oil and a bitter constituent, has similar uses to that of helianthus. The plant is a native of southern Europe, and is cultivated to a considerable extent. The akenes are 4 to 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ In.) long, not curved, flattened, smooth, glossy, light-brown with black or blackish striæ, oblique at the apex, and crowned by a yellowish margin, from the center of which the base of the style projects; inodorous; taste mucilaginous, oily, and somewhat bitter.

NIGER-SEED OIL is similar, and is obtained from *Guizotia Abyssinica* Cass. (*G. oleifera* DC. ; *Verbesina sativa* Roxb.), native of western Africa and considerably cultivated in the tropics of the Old World.

MADIA OIL is expressed from the akenes of *Madia sativa* Molina, an annual herb of Chile and cultivated in a number of countries. These akenes are brownish-gray, 4-angled and 4-ribbed, and destitute of pappus.

DRUGS USED WHOLLY OR CHIEFLY FOR THEIR VOLATILE OILS.

LEUCANTHEMUM or CHRYSANTHEMUM, the common *White, Ox-eye, Bull, Dog, Field, Moon* or *Maudlin daisy, Horse-gowan, Goldens* or *Great Marguerite*, is the flowering herb, or the flower-heads separated, of *Chrysanthemum Leucanthemum* L. (*Leucanthemum vulgare* Lam.). The plant is a native of Europe and Asia, and was introduced for ornament into America, where it spread vigorously as a pasture-weed. It is too well known to require description. The herbage is pleasantly aromatic and slightly bitter, and contains about $\frac{1}{6}$ of 1 per cent. of a greenish volatile oil. Perrier found this to combine the odors of mint and chamomile, to have a specific gravity of 0.932 at 15° C. (59° F.), a refraction index of 1.4931 at 18° C. (64.4° F.), to boil at 160° C. (320° F.), soluble in 10 parts of 70 per cent. alcohol, solidifying in a mixture of ether and solid carbon dioxide, and of an acid reaction. The drug has been used as a diuretic, antispasmodic, and mucous membrane tonic; large doses said to be emetic. Several cultivated species of Chrysanthemum of China, two of which have been identified as *C. Sinense* Lab. and *C. Indicum* L., are there largely employed medicinally, and are important articles of trade under the names *Hang-chu* or *Kan-chu*.

BIDENS L.—Several North American species of this genus (the *Beggar-lice* or *-ticks*) are used for their aromatic-stimulant properties, depending apparently upon their volatile oils. The most important is *B. bipinnata* L., the *Spanish needles* or *S. Beggar-lice*, a common and pernicious weed, especially of the warmer districts. It has a slender, quadrangular, branched stem about 3 to 10 Dm. (1 to 3 Ft.) high, opposite, triangular-ovate, bipinnate leaves, the segments cordate at the base and acute, the small heads on long, slender, erect peduncles, with a double involucre, the outer loose, 3 or 4 short, yellow, dark-veined rays and slenderly quadrangular, occasionally triangular, akenes bearing a retrosely barbed slender and sharp awn at each angle. It is aromatic, but not agreeably so, and yields an acrid after-taste. Its stimulant and antispasmodic properties have been utilized in the treatment of hay-fever. Except that it contains a certain amount of volatile oil, its constituents are not known. *B. tripartita* L. is the European *Swamp beggar-ticks, Water-hemp, Wasserhanf*, or *Chanvre aquatique*, and is employed somewhat similarly. Spanish needles is said to be stimulant, expectorant, and diaphoretic. A hot infusion of the drug has been popularly employed in the treatment of amenorrhœa, and has also been recommended as a remedy in asthma and in bronchial and laryngeal affections.

GNAPHALIUM.—One of the most interesting groups of plants of this family, from a medicinal point of view, are the *Gnaphalinæ*, including a number of species of *Gnaphalium* L., *Antennaria* Gaertn., and *Anaphalis* DC., all common and abundant in the eastern and some other parts of North America, and some similar species of other countries. All these plants are more or less white-woolly, and all give off in drying a peculiar and characteristic

odor, reminding one somewhat of that of elm bark, dried medick flowers, and tussilago herb. The peculiar hydrocarbon or group of hydrocarbons to which these odors are due have never been subjected to proper investigation. Since numerous plants possessing them are used for the same or very similar purposes by peoples remotely located and isolated from one another, the probabilities are strong that such uses are well founded and might be developed in important ways. Their special application is as soothing expectorants, but, because of the presence in them of glucosides or other bitter principles, they possess also more or less marked stomachic properties. The following drugs of this group require special attention: *Gnaphalium obtusifolium* L. (*G. polycephalum* Mx.), the *Sweet, Field, Old-field,* or *White balsam, Life-everlasting, Chafe-* or *Chaff-weed*) is a very abundant plant in dry, open, or shrubby fields throughout eastern and central North America, blooming in late summer and fall. The entire plant is white-woolly; the stems 3 to 8 Dm. (1 to nearly 3 Ft.) high, more or less branched above; leaves lanceolate, the uppermost narrow, sessile, narrowed at the base, at least the smaller ones acute, green on the upper surface, mostly 5 to 7 Cm. (2 to 3 In.) long, entire or somewhat wavy on the margin; heads numerous, crowded, erect, about 6 Mm. (¼ In.) long; involucre more or less bell-shaped, white or light-brown, the scales obtuse, thin, and papery; receptacle flat or slightly convex, pitted, naked; florets all tubular, the outer very slender, pistillate, the central broader and perfect; akenes oblong, glabrous; pappus of rather few capillary bristles. *Gnaphalium polycephalum*, as well as the other species of *Gnaphalium*, has been employed to some extent in medicine, but is probably of little value. A poultice made from the leaves and flowers has been recommended as an application to unhealthy ulcers, and an infusion [½ ounce (16 Gm.) of the plant to 1 pint (480 Cc.) of boiling water] has been employed in doses of a wineglassful in the treatment of chronic bronchitis, chronic diarrhœa, and in hemorrhagic affections. *G. sylvaticum* L., though growing in North America, is more abundant in Europe, where it is variously known as *Wood cudweed, Golden motherwort,* or *Owl's crown.* It is distinguished from the last by the arrangement of its heads in spikes, or spike-like panicles, and by its linear leaves. *G. uliginosum* L., of the same regions, the *Low, Mouse ear,* or *Marsh cudweed, Small life-everlasting,* or *Dysentery weed,* is a low, widely spreading plant, with much smaller leaves, the heads only about two-thirds as large and the involucral scales dark-brown. Quite as largely employed is *Anaphalis margaritaceæ* (L.) B. et H. (*Gnaphalium m.* L.; *Antennaria m.* Hook.), the *Pearly* or *Large-flowered everlasting, Everwhite, Indian posy, Poverty weed,* etc., which grows throughout the northern hemisphere. The plant has a similar habit to that of *Gnaphalium obtusifolium*, but grows chiefly in clumps and is stouter, denser, and more leafy. It is distinguished from the related genera by the pappus bristles, which are not thickened above. Its leaves are longer and relatively narrower, its heads broader than long, the scales at length roughly spreading. Several species of *Antennaria* are employed. Like *Anaphalus*, this genus is dicœcious or polygamous and the bristles of the pappus are thickened upward. The species most commonly employed are *A. plantaginifolia* (L.) Richards (*Gnaphalium p.* L.), the *Ladies'* or *Indian tobacco, Pincushion plant, White plantain, Spring* or *Early cudweed* or *Life-everlasting*, exceedingly common throughout eastern North America, and one of the earliest-blooming of spring plants, in dry meadows, where it grows in patches, spreading by runners. The pistillate stems range from 15 to 30 Cm. (6 to 12 In.) high, the leaves an inch or more long, mostly obovate, 3-ribbed, greenish above, silky underneath, those of the stem lance-oblong. The heads are closely clustered, white or occasionally a little pinkish, 8 to 12 Mm. (⅓ to ½ In.) long, and about as broad when fully mature. The staminate plant is only about half as tall, and all its parts are smaller. *A. dioica* (L.) Gærtn. (*Gnaphalium d.* L.), having a somewhat broader range, known by the same names, also called *Cat's-ear, -foot,* or *-paws, Katzenpfoetchen, Pied de chat,* is even more largely employed, the flower-heads being an article of commerce under the name *Flores Gnaphalii* or *Flores pedis cati.* The very similar plant of North America which has gone under this name is *A. aprica* Greene.

A number of species of *Helichrysum* Vaill., especially *H. arenarium* (L.) Moench (*Gnaphalium a.* L.), the *Strohblume, Katzenpfoetchen,* or *Immortelle,* yielding the *Flores Stoechados,* and *H. Stoechas* (L.) DC. (Galen's *amaranthon*), are used as stimulants, antispasmodics, and diuretics, because of their large content of volatile oil, and also to some extent as anthelmintics.

Various species of the genus *Pluchea* Cass., especially *P. camphorata* (L.) DC. (*Erigeron c.* L.), the *Camphor-plant, Spicy* or *Salt marsh fleabane,* and *P. odorata* Cass., are noted as containing a very fragrant sort of camphor, on account of which they have been domestically employed for their stimulant or antispasmodic effects. *Blumea balsamifera* DC. (*Pluchea b.* Cass.) is very similar. The plucheas are common salt-marsh plants along our Atlantic and Gulf States. They exhale a pleasant camphoraceous odor when bruised, whence the name of the common species. In Brazil, *P. Quitoc* DC. is commonly employed as an antispasmodic and carminative. In India, *P. lanceolata* Oliv. is similarly used under the name *Ra-sana* or *Koura-sana.*

In the higher Andes grows a large mullein-like plant, *Culcitium canescens* H. B. K., closely related to Arnica, but apparently belonging, as to constituents, to the group under

consideration, and most highly esteemed by the Aymara and Quichua Indians in the treatment of pectoral complaints.

AGERATUM CONYZOIDES L., cultivated for ornament and native of tropical America, where it is the commonest of weeds, bordering the roadsides for miles together, apparently contains considerable volatile oil, and is a diuretic and a reputed emmenagogue. *Actinomeris helianthoides* Nutt. appears to act very similarly. It is quite distinctly diuretic, which property has led to its being commonly known and medicinally employed, under the names *Gravel-weed* and *Diabetes-weed*, in the treatment of chronic cystitis.

RUDBECKIA.—Members of the genus *Rudbeckia* L., best known by the common names *Yellow daisy* or *Black-eyed Susan* (*R. hirta* L.), have contributed a number of little-used drugs, the most important being *R. laciniata* L. (*Thimble-weed*, *Tall cone-flower*, or *Cone sunflower*), a very tall species of the United States. Its constituents are unknown. There is some evidence to indicate its fatally poisonous effects upon sheep, though it is not impossible that *Helenium* has in these cases been mistaken for it. It has been considerably used by the eclectics as a stimulating diuretic, in the form of the decoction, very freely administered. The herbage of *Sphæranthus Indicus* L. (*Mundi*, *Murmuria*, etc.), of India, contains a cherry-colored volatile oil, and is used as a deobstruent and aphrodisiac, and in other ways as a stimulant.

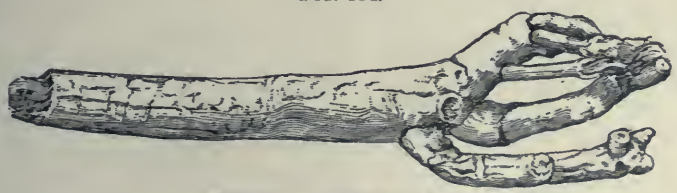
LYGODESMIA JUNCEA Don, the *Prairie pink* of the Rocky Mountain region, is one of a number of related plants which have been employed as galactagogues, probably on the basis of mere ignorant assumption, in view of their milky juices. The juice of this, like those of the related dandelion, lettuce, etc., is bitter. The plant has been suspected of poisoning stock, though direct evidence is wanting.

SOLIDAGO (*Golden rod*).—A number of species of this large genus have been employed in medicine, *S. odora* Ait., the *Sweet* or *Fragrant golden rod* or *Blue Mountain tea*, having at times held a rather important place in materia medica. Its stem is slender, almost perfectly smooth, 0.5 to 1 M. (1½ to 3 Ft.) high, nearly simple. The sessile alternate leave are linear-lanceolate, 5 to 10 Cm. (2 to 4 In.) long, acute, the margins entire but roughish, the midrib prominent, the venation not so. Held against the light, they are pellucid-punctate. The stems terminate in a secund panicle of bright-yellow flowers. The heads are rather small for the genus. The odor is pleasant, somewhat resembling that of anise, the taste aromatic and somewhat astringent. The leaves contain nearly 1 per cent. of a peculiar volatile oil, which has been commercially distilled. There is also a small amount of tannin. The drug is used as a mild carminative and antispasmodic, and to some extent as an intestinal astringent. It has also been employed in combination with ambrosia in the immunization treatment of hay fever, the beginning dose being 2 minims (0.10 Cc.) of the fluid extract, and gradually increased to 20 minims (1.3 Cc.). This plan of treatment is, however, without scientific basis. In some sections of the United States the leaves are considerably used as a substitute for tea. A number of other species of *Solidago* are medicinally employed, their properties apparently depending in variable proportions upon their content of tannin and volatile oil. *S. Virgaurea* L., the *Aaron's rod* of Europe, *Wound-wort*, *Goldruthe*, *Heidnisch-wundkraut*, *Verge d'or*, *Vara de oro*, is quite largely employed as a diuretic and vulnerary.

DRUGS EMPLOYED CHIEFLY FOR THEIR RESINS OR OLEORESINS.

ECHINACEA.—A great deal of attention has been directed during recent years to the two plants *Brauneria purpurea* (L.) Britton (*Rudbeckia p.* L.; *Echinacea p.* Moench, the *Purple cone-flower*, *Red sunflower*, *Black Samson* or *Nigger-head*) and *B. pallida* (Nutt.) Britton (*Rudbeckia p.* Nutt.; *Echinacea angustifolia* DC.), the *Pale purple cone-flower*, and considerable of a commercial demand for them has grown up. Both are plants of the central

FIG. 134.



Echinacea angustifolia (⅔ Nat.).

and southern United States. The first-named is supposed to be employed, but both are probably collected. The drug occurs chiefly in pieces about 7 to 15 Cm. (3 to 6 In.) long, of much longer roots, 6 to 25 Mm. (¼ to 1 In.) thick at the crown, which divides into several erect, rather slender branches; cylindrical and only slightly tapering; of a rather dark gray-brown, from very slightly to strongly longitudinally short-wrinkled, and bearing occasional capillary rootlets; fracture short and weak; consistency rather soft and resinous; transverse section exhibiting a rather thin gray-brown bark, a blackish-gray cortex, and irregular, bright-

yellow or greenish-yellow wood-wedges, the parenchyma thickly charged with resin-cells; odor rather faint but peculiar; taste moderately aromatic, with a suggestion of decay or mustiness, afterward acrid and sialagogue. It contains a minute amount of an alkaloid and 1 per cent. or less of an acrid resinous substance, nearly colorless and possessing the peculiar taste of the drug. This resin is apparently the active principle. *Echinacea* is stated to possess diaphoretic, sialagogue, and alterative properties. Its administration has been recommended in syphilitic and strumous conditions, and it is said to be especially useful in treating chronic ulcers which have not been benefited by the iodides or other alteratives. The freshly scraped root has been employed by the Sioux Indians as a remedy for hydrophobia, snake-poisoning, and septic conditions. The dose of the powdered drug is from 15 to 30 grains (1–2 Gm.).

Polymnia.—The root of *Polymnia Uvedalia* L., the *Bear's foot*, *Yellow-* or *Large-flowering leaf-cup*, closely related to Inula, is very largely employed in the United States. Although its investigation and the development of its use represent the worst fallacies of the homœopathic and eclectic schools, there is sufficient evidence of its being a useful alterative and deobstruent. Although commonly used as an external application, its stimulating effects are apparently slight, except through internal administration. Polymnia is a coarse perennial herb of rich woodlands in the eastern United States, 3 to 6 feet high, the very stout branched stem rough-hairy, the large triangular 3-lobed opposite leaves growing upon short dilated petioles, the lobes acute, the inferior surfaces hispid or scabrous. The upper pairs are sessile and so placed as to form a sort of cup. The inflorescence is corymbose, the heads about 6 Cm. (2 or 3 In.) broad, the involucre cup-shaped, double, the outer scales ciliate. The rays are bright-yellow. The drug is sometimes a foot in length and a half inch in diameter at the upper part, where several vertical branches are frequently given off. Other branches are frequently produced, and the main root commonly terminates in several branches. It is brown and heavily wrinkled externally, white or often greenish internally, and of a soft texture. Its odor is heavy and disagreeable, its taste resinous. Its constituents are volatile oil, soft resin divisible into two portions, the one dark-brown and hard, the other pale-yellow and balsam-like. The latter is apparently the most important constituent. There is also a large amount of glucose, a small amount of tannin, and a body which is apparently a glucoside. Polymnia has been recommended as a tonic, stimulant, laxative, and anodyne. When given internally, it is supposed to increase nutrition and to aid in the elimination of waste products. Internally, the drug has been used in the treatment of chronic rheumatism, scrofula, and various glandular enlargements. An ointment containing 2 drachms of the fluid extract in 1 ounce of fresh lard has been applied over the spleen when that viscus is enlarged from malarial infection. Its application in mastitis, lumbago, and enlargement of the liver is also alleged to have been successful. The dose of the fluid extract is 3 minims (0.20 Cc.), every 3 or 4 hours, gradually increased.

Silphium is the rhizome of *Silphium perfoliatum* L., the *Indian cup*, *Indian cup plant*, or *Ragged cup*, and is used almost precisely like polymnia. In habit the plants are very similar, but silphium is distinguished by its square stem. The large leaves are opposite, broadly ovate, coarsely toothed, and connate by their broadly winged petioles, or the upper sessile ones by their broad bases. The flower-clusters are 3-branched, the involucres squarrose, the akenes winged. The rhizome is horizontal, elongated, crooked, cylindraceous, markedly pitted and rough with small roots, its transverse section exhibiting large resin-cells. Its important constituent is one or more acrid resins. Two other species are similarly used, and are notable on account of the natural exudation from their stem and herbage of a peculiar turpentine-like substance. That of *S. laciniatum* L. (*S. gummiferum* Ell.), of the southern United States, the *Rosin weed*, *Compass plant*, or *Pilot weed*, so called because its large lower leaves are directed north and south, has been analyzed and found to contain 20 per cent. of volatile oil and 37 per cent. of resin. *S. terebinthinaceum* Jacq., of the same region, is also known as *Rosin plant*, and as *Prairie dock* or *Turpentine sunflower*.

Balsamorhiza.—Considerable attention has been directed to *Balsamorhiza terebinthinacea* Nutt., of the Rocky Mountain region, where the Indians are said to employ it as a medicine. It has been reported as aiding in reformation from the tobacco-habit. Sayre describes the root, the portion used, as much contorted, 1 to 6 inches long, the large short crown dividing into numerous hairy branches, of a nearly black color, an open spongy texture, yellowish-white within, and very abundantly supplied with yellow resin-glands. The odor is strongly terebinthinate, the taste pungently aromatic and somewhat acrid. It is highly combustible. It was found to contain about 0.5 per cent. of volatile oil, 5 per cent. of fat, and 9 per cent. of resin. No careful attention has been given to its medicinal properties. So abundant is the oleoresin in the bark of the root that it exudes upon the slightest wounding, or even, it is said, spontaneously. The roots of some species of this genus are said to be eaten by the Indians.

Liatris.—Under this name, the rhizomes of several species of the American genus *Lacinaria*, Hill, have been employed as diuretics. *L. scariosa* (L.) Hill (*Serrutula s.* L.; *Liatris s.* Willd.) grows throughout the eastern and central United States, and is known as the large *Button snake-root*, *Blue blazing star*, or *Gay feather*. The rhizome of this species par-

ticularly is largely employed by the eclectics in female diseases. *L. spicata* (L.) Kuntze has not quite so wide a range, and is known by the same name, also as *Backache root*, *Rough root*, or *Prairie pine*. *L. squarrosa* (L.) Hill is the *Scaly blazing star* or *Colic root*. It occurs chiefly in the central United States. These drugs are aromatic, somewhat terebinthinate, bitter and more or less acrid. The second-named species only has been chemically examined. The only important constituents were about 0.1 per cent. of volatile oil, nearly 5 per cent. of resin, and about 2 per cent. of a caoutchouc-like body.

SPILANTHES OLERACEA L., the *Para cress*, native of tropical America, and cultivated and escaped in most tropical countries, is a pungent plant, used as a cress. Medicinally, it is employed as a stomachic and antiscorbutic. Its properties are probably due to a soft pungent resin, and perhaps in part to the crystallizing substance *spilanthin*, which is soluble in alcohol but not in water. It is a popular application for toothache, in tropical America. This drug has been official in the Austrian Pharmacopœia. Somewhat similar and similarly employed, though more bitter, is *S. Acmella* L. (*Acmella Mauritiana* Rich.).

GYMNOSPERMA MULTIFLORA DC. is known as *Tatalancho* in Mexico, where it is much used as a vulnerary and for its local analgesic effects. It contains volatile oil and resin.

DRUGS USED CHIEFLY FOR THEIR BITTER PRINCIPLES.

CARDUUS.—Various species of thistle have been more or less employed in medicine, and the *Blessed thistle*, *Cnicus Benedictus* L. (*Centaurea b.* L. ; *Carduus b.* Steud. ; *Carbenia b.* Adans. ; *Calcitrapa lanuginosa* Lam.), is still quite an important article of commerce. It is a European plant, sparingly introduced to the United States, and is variously known as *Blessed*, *Cursed*, *Holy*, *Spotted*, or *Bitter thistle* or *cardus*, *Spinnendistel*, *Chardon benit*, or *Cardo santo*. The stem is 30 to 60 Cm. (12 to 24 In.) high, stout and coarse, angular, branching, usually of a reddish color ; leaves alternate, oblong to lance-ovate, sinuately pinnatifid and dentate, the teeth terminating in soft spines. The lower are sometimes a foot in length and borne on angular winged petioles, the upper smaller and sessile or the uppermost decurrent ; heads solitary at the ends of the branches, ovoid, about 30 Mm. (1¼ In.) long, the involucral scales terminating in yellowish spines ; akenes well marked by their double pappus, the outer of 10 short teeth, the inner of 10 long, alternating with 10 short bristles. The drug is grayish-green, has a peculiar, mild, and not unpleasant odor, and a saline and very bitter taste. The bitter principle has been isolated under the name of *cnicin*, is prepared like salicin, occurs in colorless needles, freely soluble in alcohol, slightly in cold water and ether, dissolving in strong hydrochloric acid with a green, and in sulphuric acid with a red, color. Blessed thistle possesses the properties of a simple bitter. It is also said to be an hepatic and urinary stimulant. It may be employed in atonic dyspepsia, especially if hepatic torpor exists, and, like other bitters, it has been successful in the treatment of mild malarial infections. Overdoses of its active principle *cnicin* sometimes produce nausea, vomiting, intestinal pain, and diarrhœa. The dose of the infusion (1 ounce to 1 pint) is from 1 to 2 fluidounces (30–60 Cc.) ; of the powdered drug, from ½ to 1 drachm (2–4 Gm.) ; of cnicin, from 5 to 8 grains (0.30–0.50 Gm.) ; the latter amount, however, may produce nausea. *Carduus arvensis* (L.) Robs. (*Serratula a.* L. ; *Cnicus a.* Hoffm. ; *Cirsium a.* Scop.) is the common *Canada thistle*, also called *Corn*, *Boar*, *Hard*, *Prickly*, *Creeping*, or *Sharp thistle*, *Dashel*, or *Dodger*, among the worst of American weeds. This contains a glucoside and, it is said, an alkaloid.

C. LANCEOLATUM L., the common *Bull*, *Bur*, or *Scotch thistle*, has probably a similar composition, and is similarly employed as a diuretic and tonic.

Several species of *Centaurea*, especially *C. calcitrapa* L., the *Star thistle*, and *C. Cyanus* L., the common cultivated *Corn flower* or *Bluebottle*, both native of Europe, are credited with properties similar to those of the blessed thistle, and are similarly employed.

HELENIUM.—Various species of the genus *Helenium* L. are known as *Sneeze-weed*, in allusion to the effects of inhaling the volatile substance given off by the crushed flower-heads. They possess active physiological properties and appear well worthy of thorough investigation. *H. autumnale* L., the *Swamp* or *False sunflower* or *Yellow-star*, common along river-banks throughout most of North America, except the far north and far west, has been quite largely employed as a drug and is a common article of commerce. It is a stout perennial, the stem somewhat quadrangular, winged by the decurrent leaves, which are alternate, 5 to 12 Cm. (2 to 5 In.) long, lanceolate, narrowed at the base, acuminate and acute, and acutely serrate. The long-peduncled flower-heads are well characterized by their drooping, bright-yellow rays and subspherical disk, which is sometimes nearly an inch broad. The drug is nearly odorless, but very bitter. The important constituent appears to be a bitter glucoside soluble in alcohol and boiling water. The amounts of volatile oil and tannin are very small. The plant has been known as a cattle poison. It is used as an errhine. Other species have similar properties, and *H. tenuifolium* Nutt., the *Fine-leaved sneeze-weed* of the southern United States, is a severe poison, the effects being strongly narcotic. A Mexican species possesses even greater activity.

XANTHIUM STRUMARIUM (*Cocklebur*, E. ; *Lampourde, Petit glouteron*, Fr. ; *Spitzklette, Knopfklette*, G.) is a coarse-looking weed, common in waste places throughout North America, Europe, and northern Asia. The leaves are alternate, long-petiolate, triangular heart-shaped, and rough-hairy. The sterile flowers are in short terminal spikes. The fertile flowers are numerous, in axillary clusters, and produce flat, oblong akenes, without pappus and enclosed in the enlarged involucre, which is oval or oblong in shape, nearly 25 Mm. (1 In.) long, and densely beset with hooked prickles. Zander (1881) obtained from 100 parts of the fruit 5.2 ash, 38.6 fat, 36.6 albuminoids, 1.3 xanthostrumarin and organic acids, besides sugar, resin, etc. *Xanthostrumarin* seems to be a glucoside, is yellow, amorphous, soluble in water, alcohol, ether, benzol, and chloroform, and yields precipitates with group reagents for alkaloids and with ferric chloride, lead acetate, and salts of other metals, but not with tannin or gelatin. M. V. Cheatham (1884) obtained only 14.5 per cent. of fixed oil, and a principle which was precipitated by tannin.

X. spinosum L., *Spiny clotbur*, is indigenous to southern Europe, but has become somewhat naturalized in waste places of the United States and most civilized countries. It has shortly petiolate, lanceolate, or ovate-lanceolate leaves, which are either cut-toothed or the upper ones entire, and have at the base sharp, 3-forked, yellowish, stipulate spines, nearly 25 Mm. (1 In.) long. The fertile axillary burs are crowned with an inconspicuous beak. The alkaloid, the presence of which was announced by Guichard (1877), is regarded by Yvon as a bitter resin, soluble in both alcohol and ether. A number of American species are very similar and probably share in the above properties. *Xanthium spinosum* is said to be a diuretic, diaphoretic, and sialagogue. It has been credited with the cure of intermittent fever, and was formerly thought to be of value as a prophylactic against hydrophobia. The dose of the dried leaves is 10 grains (0.60 Gm.), 3 times daily, for a period of several weeks.

BACCHARUS.—This American genus, of some 300 species, mostly tropical, yields a number of drugs, noted either for their intense bitterness or for their aromatic properties, many yielding oleoresinous exudations. *B. genistiloides* Pers., of tropical America, and some species so closely related as to be almost indistinguishable from it, belong to the bitter division and are quite extensively used under the name *Carquega amargosa*. They are also said to be largely exported for use in proprietary bitters. One of these is an important anthelmintic in the Andean region. *B. cordifolia* DC., of Brazil, is similarly bitter, and is said to be a seriously fatal sheep and cattle poison. *B. glutinosa* Pers. (*B. Alamani* DC. ; *Molina viscosa* R. et P.) is largely used in Mexico and in the Andes in the treatment of catarrh. Other species of the genus are used as vulneraries. *B. halamifolia* L., the *Groundsel bush, Cotton-seed*, or *Ploughman's spikenard*, of the Atlantic coast region, is used as an aromatic bitter, while *B. Pilularis* DC., the *Kidney root* of the Californian coast, is used as a diuretic.

NABALUS.—Most species of the North American genus *Nabalus* Cass. (*Prenanthes* Vaill.) are bitter, and a number of them have been used as bitter tonics. *N. albus* (L.) Hook. (*Prenanthes a.* L. ; *Harpalyce a.* Don) is still largely employed by the eclectics, and is a commercial drug under the name *Lion's foot, Rattlesnake root, White lettuce*, or *Cancer weed*. *N. serpentarius* (Pursh.) Hook. (*Prenanthes s.* Pursh. ; *N. Fraseri* DC.) has been regarded as a variety of the last, but is probably distinct. It is similarly used under the same names, and especially under that of *Gall-of-the-earth*. It grows from a tuberous turnip-shaped root, occasionally as much as 2 or 3 inches in diameter. The stem is 3 to 10 Dm. (1 to 3 or 4 Ft.) high, usually smooth, green, and irregularly angled ; leaves exceedingly variable, being ovate and hastate, cordate at the base, acute or obtuse, varying from nearly entire to more or less dentate, pinnatifid, or even palmately divided, the upper ones becoming narrow and entire ; inflorescence a broad panicle, the widely spreading branches upturned at the ends ; pendulous heads bristly, 5 to 6 Mm. ($\frac{1}{5}$ to $\frac{1}{4}$ In.) wide and a little more than twice as long ; involucral scales about 8 ; flowers ligulate, yellowish-white, 5-toothed ; receptacle flat and naked ; akenes oblong or linear, about 10-ribbed ; the pappus of copious, somewhat stiff bristles, varying from white to tawny and rather longer than the involucre. The herb is intensely bitter, but its constituents have not been studied. The first-named species is very similar, but is usually nearly twice as tall, more slender, the stem glaucous and usually purple, the leaves thinner. *M. altissimus* (L). Hook. (*Prenanthes a.* L.), the *Tall lion's-foot*, etc., is similarly employed. All these plants are common and abundant in the rich woodlands of eastern North America. Nabalus has been reported as a cure for rattlesnake-bites. It has also been given in the treatment of dysentery. The fresh milky juice may be employed internally, and a poultice made from the leaves applied externally and frequently changed.

PEREZIA.—The members of the genus *Perezia* Lag., of the southwestern United States and southward in tropical America, contain an abundance of one or more bitter principles to which, probably, are due their distinctly laxative properties. The rhizome of *P. adnata* Gray (*Trixis Pipitzahoac* Schaffn. ; *Dumerelia Alamani* DC.) is an important Mexican drug, under the name of *Pipitzahoac*. It is described by Th. Greenish (1884) as 8 to 10 Cm. (3 to 4 In.) long, 2 Mm. ($\frac{1}{12}$ In.) thick, longitudinally wrinkled, brown, bitter, and rather persistently pungent ; it has a thick central pith, surrounded by about 8 short fibrovascular

bundles, on the outside of which, in the thickish bark, are contained a number of cells forming a circle and containing a yellow crystalline substance; stone-cells of a somewhat stellate appearance are scattered in the parenchyma. The yellow principle, *pipitzahoic acid*, $C_{15}H_{10}O_3$, was examined by C. M. Weld (1855); it crystallizes in golden-colored glossy scales or plates; hence it has been called *vegetable gold;* it is nearly insoluble in cold water, dissolves readily in alcohol and ether, melts near 100° C. (212° F.), sublimes when heated with care, and acquires an intense purple color with alkalies and alkaline earths. The same compound was obtained by Charles Mohr (1884) from the roots of *Perezia Wrightii* and *P. nana* Gray, of southwestern Texas—from the latter in smaller quantity; it separates from the decoction in needles. The acid acts as a drastic purgative in doses of 4 to 8 grains (0.25–0.50 Gm.), and imparts a greenish color to urine.

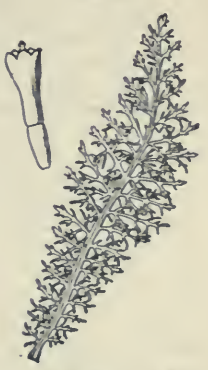
NEUROLÆNA LOBATA R. Br. (*L'herbe à pique*), of tropical America, is used in the West Indies as a quinine substitute and in the treatment of dysentery. It contains about 1 per cent. of an extremely bitter alkaloid.

DRUGS USED FOR THEIR BITTER AND AROMATIC PROPERTIES.

PARTHENIUM (*Feverfew* or *Featherfew*, *Wild chamomile*, *Bertram*, *Mutterkraut*, *Matricaire*) is *Chrysanthemum Parthenium* (L.) Pers. (*Matricaria P.* L.; *Pyrethrum P.* Smith; *Tanacetum P.* Schultze), a chamomile-like plant of Europe, the double-flowered form much cultivated in gardens. The stem is about 60 Cm. (2 Ft.) high, furrowed, and has alternate, petiolate, ovate, twice pinnately cleft leaves, with obovate or oblong, mostly toothed lobes, each tooth terminating in a white point. The flower-heads are in small cymes at the ends of the branches, have an involucre composed of linear scales in 2 rows, a naked hemispherical receptacle, white ligulate obovate and 3-toothed ray-florets, and tubular yellow disk-florets. The herb (*Herba matricariæ*) has a peculiar odor resembling that of chamomile, but less agreeable, and a bitter, somewhat acrid taste. It contains a powerful volatile oil, its stearopten having the composition of camphor, fusing at 170° C. (338° F.) and lævogyre. There are also considerable tannin and an unknown extremely bitter substance. The drug is a valuable carminative, stomachic, and antispasmodic, its properties and uses closely resembling those of chamomile. The genus *Parthenium* L. is quite distinct, but yields several species which are similarly employed. *P. Hysterophorus* L. (*Wild feverfew*, *Wild wormwood*, *Indian mugwort*, or *Whitehead*), of the southern United States and tropical America, is the most important. Its composition has been considerably studied, but the results are indefinite. Its amaroid has been reported as glucosidal and again as alkaloidal, but it is probably neither. Large doses have an antipyretic effect. *P. integrifolium* L. (*P. amplectens* Raf.), the *Cutting almond*, *Nephritic plant*, *American feverfew*, and one of the plants known as *Prairie dock*, of the southern and central United States, appears to have a very similar composition and properties, and is used as a diuretic and antiperiodic. These plants differ from true feverfew in their size, being usually from 5 to 15 Dm. (about 2 to 5 Ft.) high, and widely branched, by their large leaves, the larger frequently 3 Dm. (1 Ft.) long, or in the first species even twice that size. In that species they are bipinnatifid; in the second crenate-dentate, the lower petioled, the upper sessile. The heads are much smaller than in feverfew, the rays only about 5, instead of numerous as in feverfew, and the drugs are more bitter and less aromatic.

ACHILLEA, *Yarrow*, *Milfoil*, *Schafgarbe*, *Schafrippe*, *Millefeuille*, *Herbe aux charpentiers* (*Herba*, or *Summitates Millefolii* of the Austrian Pharmacopœia), is the flowering herb of *A. Millefolium* L., a common roadside weed of Europe and Asia, as well as of North America, where it has been introduced, and is one of the most ancient of drugs. Although its present employment is slight in comparison with that of the past, it is still frequently seen in commerce. It is a perennial herb, rarely exceeding 60 Cm. (2 Ft.) in height, the stem rather stout, branching only at the top, furrowed and hairy; radical leaves petioled, 10 to 25 Cm. (4 to 10 In.) long, and about one-third as broad, the stem-leaves nearly sessile, about half as large and rather narrower, alternate, soft-hairy, deeply and finely 2 or 3 times pinnatifid, the lobes linear-spatulate, crowded, 3 to 5 cleft, finely mucronate and beset underneath with small oil-glands; inflorescence a white, or occasionally pink, dense, flat-top corymb; involucre oblong, 4 or 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ In.) long, the scales imbricate and keeled; receptacle flat and chaffy; rays 4 or 5, pistillate, fertile, the disk-flowers few, perfect, the tube yellowish, the limb whitish; akenes oblong, flattened, without pappus. The drug somewhat resembles chamomile in odor, and is bitter and somewhat astringent. The herbage yields about 0.1 per cent. of a blue or dark-green butyraceous volatile oil. The bitter principle, *achilleine* ($C_{20}H_{38}N_2O_{15}$), is an alkaloid and is present in small amount, and exists also in *A. moschata* Jacq. The latter species (*Ptarmica m.* DC.) is considerably employed in Europe

FIG. 135.



Achillæa leaf (½ Nat.); floret (× 4½).

under the name *Ivæ*, or *Genippi*, for the same purposes. The leaf-lobes of this species are linear and entire, and the drug is much more strongly aromatic and bitter. Its volatile oil has been called *ivaol*. Besides the alkaloid named above, it contains two others, *achilletine* ($C_{11}H_{17}NO_4$) and *moschatine* ($C_{21}H_{27}NO_7$). *Ivain* ($C_{24}H_{42}O_5$) is a soft yellow substance, soluble in alcohol but not in water. Achillea possesses tonic, stimulant, and astringent properties. Formerly it was employed to a limited extent as an emmenagogue, and was believed to be useful in the various atonic conditions common to the organs of reproduction. The drug has been recommended in chronic, depraved conditions of the mucous membrane of the entire gastro-intestinal tract, but is rarely employed. It is usually prescribed in hot infusion, made with 1 ounce (30 Gm.) of the drug and 1 pint (480 Cc.) of boiling water, in doses of from 4 to 6 fluidounces (120–180 Cc.). The volatile oil may be employed in the dose of 30 minims (2 Cc.). *A. ptarmica* L. (*Sneeze-weed, Bertramgarbe, Herbe à éterneur*) is similarly used.

Ambrosia, or *Rag-weed*, as commonly understood, is the flowering herb of *A. artemisifolia* L., the common *Rag-weed, Hog-weed, Tassel-weed, Bastard* or *Roman wormwood*, or *Wild*

Fig. 136.

A, *Ambrosia artemisifolia;* B, *A. trifida;* C, pollen-grains of A (A and B, ½ Nat.; C, much magnified).

tansy, probably the most abundant weed of eastern North America, growing along roadsides, choking out cultivated plants, and abounding especially in grain-fields after the harvest. The range of the plant is a matter of great importance. Many persons who suffer from hay-fever annually seek those localities where it does not grow, and where "hay-fever colonies" are sometimes established. The plant is a more or less hairy annual with a widely branching stem, sometimes reaching a height of 2 Mm. (6 Ft.) and almost as great a breadth. Its thin leaves, opposite below and alternate above, are more or less petioled, 5 to 15 Cm. (2 to 6 In.) long, and almost equally broad, triangular-ovate, finely once- or twice-pinnatifid, the lobes oblong to lanceolate. The sterile flowers, of a yellowish-green color, terminate the branches in long, slenderly cylindrical racemes, the heads being very small. The pistillate heads are clustered, chiefly at or near the base of the staminate racemes. Occasionally the plant is dicœcious. The fertile heads are obovoid or turbinate, and usually bear 4 to 6 short spines upon the summit. The plant is rather disagreeably aromatic and intensely bitter. Its bitter and aromatic constituents are but little known. It is said that the volatile oil does not amount to more than 0.1 per cent., and that there is nearly 3 per cent. of combined resin,

chlorophyll, and bitter glucoside. Because of its astringency, ambrosia has been employed as a local hæmostatic agent. Like other simple bitters, it has been given in atonic dyspepsia and in mild malarial affections, but it possesses no marked advantages over other bitters more commonly used in these conditions. The eclectics state that it possesses stimulant properties, and claim that it may be given with success during the typhoid state of the acute infectious fevers. The pollen of this plant is said to be the principal exciting cause of *hay asthma*, and in many cases this statement is probably correct. It is, however, denied by some writers. Its inhalation probably irritates an already hypersensitive nasal mucosa, but, according to Dr. D. Braden Kyle, it is not known whether the irritation results from "mechanical impact, continual presence, or by the impregnation of the nasal secretion with some intrinsic substance irritant to the hypersensitive membrane." Recently this drug has been recommended in conjunction with golden rod (see SOLIDAGO) in the immunization treatment of hay-fever, but this plan of treatment is not based on scientific or accurate reasoning. The beginning dose is stated to be 2 minims (0.10 Cc.), 4 times daily, of a mixture of equal parts of the fluid extracts of Ambrosia and Solidago, which is to be increased 2 minims at each succeeding dose until 20 minims (1.30 Cc.) are taken. An infusion of the tops may be made with 4 drachms (16 Gm.) in 1 pint (480 Cc.) of water, and given in doses of 1 wineglassful, as required.

A. trifida L., the *Great, Giant, Riverside,* or *Salt marsh rag-weed, Horse-cane, Buffalo-weed,* or *Wild hemp,* is a half larger and much stouter in proportion. Its color is a light or yellowish-green, instead of the dark gray-green of the former. It is rough-hairy. Its large leaves are deeply 3-lobed, the lobes lance-oblong or lance-ovate and coarsely serrate. Its bitter properties are similar to those of the preceding.

The flower-heads of *Mutisia viciæfolia* Cav. (*Scale flower, Chinchircoma*) are considerably employed in the Bolivian Andes as an expectorant in phthisis and other chronic disorders. They contain small amounts of bitter extractive and volatile oil.

DRUGS USED FOR THEIR BITTER AND ASTRINGENT PROPERTIES.

SENECIO (*Squaw-weed, Life-root, Ragwort, Female regulator, False valerian*) is the root and herb of *S. aureus* L., and is a favorite drug among the eclectics and homœopaths, and quite an important article of commerce. It was also a much-used aboriginal medicine under the names *Mequot, Nunqua* or *Nutqua,* and *Unkum.* It is a common weed of eastern North America, blooming in early spring, and quite a number of forms are variously regarded by different botanists as varieties of this or as distinct species. Doubtless all of them have been promiscuously employed. The plant is a perennial herb, nearly smooth, the rather slender fluted stems 3 to 7 Dm. (1 to 2 Ft.) or more high, simple, excepting the inflorescence. It bears a tuft of semiprostrate root-leaves, some of which reach a length of 15 Cm. (6 In.), are ovate to reniform, obtuse, crenate or dentate, and borne on long petioles. The stem-leaves are successively smaller and narrower, usually more or less incisely pinnatifid, sessile and clasping. The few heads are borne in a loose corymb on slender peduncles, are 16 to 20 Mm. (⅔ to nearly 1 In.) broad and about half as long. The involucral scales are in a single series or with a few short loose ones at the base. The rays are 8 to 12, golden-yellow, widely spreading, or at length slightly reflexed, and the disk is brownish-yellow. The receptacle is flat or nearly so, and naked. The rays are pistillate and fertile, the yellow or brownish disk-flowers perfect, the akenes oblong, smooth, 5- to 10-ribbed, the pappus of copious fine white bristles. The rhizome is short and oblique, and somewhat resembles that of arnica. The drug is bitter, astringent, and slightly acrid, but little odorous. Its constituents are unknown. *Senecio aureus* has been employed as a vulnerary by the American Indians. The eclectics claim that it possesses emmenagogue and diuretic properties, and that it not only stimulates in atonic conditions, but also regulates the menstrual function when irregular or too profuse. A decoction or infusion made from the whole plant (℥j to Oj) may be given in doses of 1 wineglassful, and repeated as needed. *Senecin* of the eclectics is obtained by precipitating an alcoholic tincture of the drug with water and collecting the precipitate.

S. vulgaris L., the European *Groundsel* or *Bird seed, Kreuzkraut, Jacobs-kraut,* or *Senecon,* is somewhat similarly used. The plant is interesting as containing a very small amount of 2 alkaloids, *senecionine* ($C_{18}H_{26}NO_6$), which crystallizes in rhomboidal tablets and is soluble in alcohol, and *senecine,* which crystallizes in needles and is soluble in ether, which the other is not. *S. Jacobæa* L. is another common European species, known under a great variety of common names, especially *Tansy ragwort, St. James-wort, Ban-weed,* or *Felon-weed,* and *Stinking Alexander,* and credited with properties similar to those of *S. aureus.* Good evidence has been adduced to show that it acts well in many cases of functional amenorrhœa. *S. Cineraria* DC. (*Cineraria maritima* L.), the common *Dusty miller* of cultivation, has attracted considerable attention from time to time because of its reputed activity in causing the absorption of soft capsular cataract, the fresh juice being instilled into the eye.

GUACO.—The leaves of *Willughbœa,* Neck. (*Mikania,* Willd.), of one or more species, more

especially *W. amara* (W.) Kuntze (*Mikania a.* W.; *M. Guaco* H. et B.), are among the numerous drugs used in tropical America under the name *Guaco*. They are markedly bitter and astringent, as well as aromatic, and although ignorantly employed in cancerous complaints, as an antidote to snake-bites, etc., they undoubtedly possess important tonic and alterative properties. The leaves range from 5 to 12 Cm. (2 to 5 In.) long and fully two-thirds as broad, are ovate and slenderly petioled, abruptly short-acuminate, rough above, soft-hairy underneath, and rather thick. A volatile oil, a bitter principle, and tannin have been found in this drug. The genus is a vast one in tropical America, and it is probable that most of the species have similar constituents and properties. One, *W. scandens* (L.) Kze. (*Eupatorium s.* L., *Mikania s.* W.), is common in eastern North America, in moist localities, twining over shrubbery, and known as *Climbing boneset* or *Climbing hemp-weed*. It has been considerably employed in indefinite ways, as an alterative, and has undoubted value as a stimulating intestinal astringent.

ERICHTITES.—Several species of *Erechtites*, Raf., especially *E. hieracifolia* (L.) Raf. (*Senecio h.* L.), one of the *Fire-weeds*, also called *Pilewort*, contain much tannin and had many uses as astringents among the aborigines and early settlers. It also contains a volatile oil somewhat resembling the oil of erigeron, but not soluble like that in an equal volume of alcohol. This herb, which has quite an extensive sale, particularly among the eclectics, is described as follows: Stem 30 to 150 Cm. (1 to 5 Ft.) or more high, stout but fleshy and weak, fluted, roughish, branching above, the branches erect, making a somewhat contracted-paniculate inflorescence; leaves alternate, of exceedingly variable size, from lance-ovate to linear, shortly petioled, irregularly and sharply toothed or sometimes subpinnatifid, thin, the upper becoming sessile and at length clasping; heads cylindrical, bristly-hairy at the base, the lower scales of the involucre short and spreading, the upper long and linear, strictly erect or even contracted at the summit. The florets are very slender, the akenes slenderly oblong and surmounted by a copious, exceedingly fine and silky, white or sometimes violet pappus.

HIERACIUM, L.—Several species of this large genus, the *Hawk-weeds*, somewhat distantly related to lettuce and dandelion, have been employed medicinally, both in Europe and America. That most generally employed is *H. venosum* L., the *Veiny-leaved hawk-weed*, *Striped bloodwort*, or *Rattlesnake-weed*. It is common in dry woodlands throughout eastern North America. It produces a rosette of nearly prostrate radical leaves, 7 to 15 Cm. (3 to 7 In.) long, and about half as broad, oblanceolate, narrowed to the sessile base, hairy, and with prominent, broad, red-purple veins. The stem is 50 to 60 Cm. (a foot or two) high, slender, bearing several small leaves, which are reduced upward to narrow bracts, and a loose and scant branched corymb of pretty deep-yellow flower-heads, consisting entirely of ligulate florets. The drug is bitter and astringent, but scarcely odorous. Its constituents have not been studied, but appear to include tannin and an amaroid. It, like the other species, has been indefinitely employed as a tonic and mild astringent. The claims that it is antidotal to the bite of the rattlesnake are doubtless fanciful, as in the case of hundreds, if not thousands, of other plants concerning which the same claim is made.

ECLIPTA.—The herbage of several species of *Eclipta* L. is used for the sake of its tannin, and more especially for its volatile oil, as an intestinal astringent and antispasmodic, and even for the cure of toothache. *E. prostrata* L., of the East Indies, introduced to tropical America, is known as *Bhangra*, *Maka*, *Garaga*, and by various other names. Besides the above uses, it is eaten as a vegetable, as is *E. spicata* Spr.

VERNONIA.—The very large genus *Vernonia* supplies a number of species, in widely separated countries, which find important domestic uses as aromatic bitters and tonics. The common American species, *V. fasciculata* Mx., or *Iron-weed*, is chiefly used in the United States, particularly by the eclectics. *V. anthelmintica* W., of the East Indies, is there quite highly esteemed as an anthelmintic.

ADENOCAULON BICOLOR Hook. (*A. adhœrescens* Maxim.) is used in Japan as an application in rhus-poisoning, the leaves being warmed and applied to the affected surface. It appears at least probable that in this case the benefit occurs mechanically, from the deposit of an adhesive protecting layer upon the skin.

CONDURANGO CORTEX, *It.*—Condurango.

Cortex Condurango, P. G.; *Condurangorinde*, G.

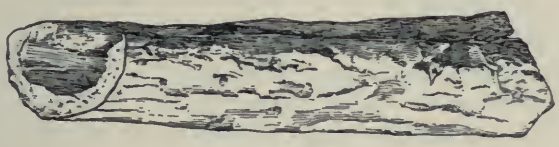
The dried bark of *Marsdenia Condurango* Nichols (non Reichb.—*Gonolobus C.* Triana.—Fam. *Asclepiadaceæ*).

Origin.—From a half-climbing or prostrate shrub of Ecuador, where it enjoys quite a repute for the cure of cancer, due apparently to the ignorant and general application of that name to various non-malignant diseases.

Description.—In quills or quilled pieces, about 10 Cm. (4 In.) or less long, and rarely exceeding 2 Cm. ($\frac{4}{5}$ In.) in diameter, the bark 2 to 6 Mm. ($\frac{1}{12}$ to $\frac{1}{4}$ In.) thick; externally brown-gray, roughened with low, broad, somewhat scale-like warts, and often wrinkled;

internally grayish- or pale brownish-white, striate; fracture short, granular or slightly fibrous in the inner layer, exhibiting under the lens a thin brown cork, a whitish or yellowish-white starchy layer, which is traversed by wavy bast-wedges and dotted with numerous brownish or

FIG. 137.



Condurango (Nat.).

yellow stone-cells; nearly odorless, taste bitter and somewhat aromatic and acrid. A clear 20 per cent. infusion prepared with cold water, becomes turbid on heating and clear on being cooled.

Constituents.—The bark (*Zimmermann*, 1891) yields 0.5 per cent. of starch, fermentable sugar, wax, light-colored resin, 0.75 per cent. of a very light deliquescent crystalline acid, 12.6 per cent. of tannin, and *condurangin*, a bitter glucoside (?). From commercial condurangin, Carra (1892) obtained a yellow substance ($C_{18}H_{28}O_7$) soluble in water and insoluble in ether, and a whitish body ($C_{20}H_{32}O_6$) insoluble in water and soluble in ether and benzin. He also found in the bark a new glucoside ($C_{40}H_{74}O_6$), which is insoluble in ether, sparingly soluble in cold alcohol, and very slightly soluble in water. These substances have been still farther investigated, Hager (*Handbook*, 1900) determining them as *a*- and *b*-condurangin. *a*-Condurangin melts at 60° to 61° C. (140° to 141.8° F.), is insoluble in water but soluble in benzene, and strikes a green color with Froehde's reagent (concentrated sulphuric acid and molybdic acid). *b*-Condurangin melts at 134° C. (273.2° F.), is insoluble in water, and gives no reaction with Froehde's reagent. Besides these, *conduransterin* ($C_{30}H_{50}O_2$), a cholesterin relative, cinnamic acid, and a minute quantity of alkaloid (Flückiger) with strychnine-like action, have been isolated.

Pharmaceutical Preparations.—FLUIDEXTRACT OF CONDURANGO, P. G.; WINE OF CONDURANGO, P. G.

Action and Uses.—Condurango has been employed in South America for many years as an alterative in the treatment of syphilis. It was introduced into medicine in 1871 as a reputed cure for gastric carcinoma, but as a specific for this condition is a complete failure. Like the other aromatic bitters, it may be employed as a stomachic, and it lessens the gastric catarrh and alleviates the nausea and vomiting which usually accompany carcinoma of the stomach. It also exercises a certain sedative effect upon the gastric mucous membrane, and may be given to relieve the pain incident to gastric ailments. Condurangin causes irritability of the stomach, nausea, and vomiting, with impairment or loss of appetite, and in large amounts produces incoördination of the muscles and convulsions, which may be followed by paralysis.

Condurango is given in the dose of 1 fluidrachm (4 Cc.) of the fluidextract, or 4 fluidrachms (16 Cc.) of the wine.

An infusion made with 1 part of the drug and 8 parts of boiling water may be given in doses of 1 tablespoonful.

Other Condurangos.—Dr. Joseph G. Ayers, U. S. N. (1871), ascertained that there are at least 10 different shrubby vines designated as condurango, said to mean *Eagle-vine;* of the majority of these, he was unable to collect the flowers and fruit. The origin of the following, however, has been determined:

GONOBOLUS TETRAGONUS DC. yields *Condurango de paloma*, from Malacatos. It is of a dark-gray or brown color, and on the dry stem is slightly wrinkled longitudinally.

ECHITES HIRSUTA R. et P. (Fam. *Apocynaceæ*) yields *Condurango de paloma*, from Zaruma. The bark has a soft, pale-yellow or white corky layer, which is a line or more thick.

ECHITES ACUMINATA R. et P. yields *Condurango de plátano*. The bark is thin and pale-gray on the outside.

GUAYAQUIL and MEXICAN CONDURANGOS are not from this source.

Other Marsdenias.—The genus contains about 70 species, distributed through all warm countries. The milk-juice of *M. erecta* (L.) R. Br. (*Cynanchum e.* L.), the *Chanik-el-Kilab* of Syria, is carminative and narcotic. The fruit of *M. Roylei* Wight, of India, is used as an alterative and antiblennorrhagic. The leaves of *M. tinctoria* R. Br. and *M. parviflora* DC., of the East Indies, yield a blue, indigo-like dyestuff.

CONFECTIONES.—Confections.

Electuaries, E.; *Conserves, Électuaires, Saccharolés mous*, Fr.; *Conserven, Latwergen*, G.

These preparations are now but little employed medicinally, compared with the extensive use made of them during the last century. A distinction was then, and in some countries is still, made between *conserves* and *electuaries*, which in the British and U. S. Pharmacopœias are now comprised under the title of Confections.

Conserves were made by covering fresh drugs with a layer of sugar; afterward by beating fresh vegetable substances with sufficient sugar until the whole was converted into a uniform soft mass. As indicated by the name, the primary object in view was to preserve the medicinal virtues of the plants thus treated, and incidentally their administration was rendered more agreeable.

Electuaries differ from conserves mainly in being mixtures of powders with pulps, syrups, or honey, and are made by triturating the ingredients together in a mortar. The powders should be very fine; when extracts are to be added, they are previously liquefied by trituration with a little water or other suitable menstruum, and gum-resins, if not pulverizable, are best converted into an emulsion to insure their uniform distribution. Soluble as well as insoluble salts may be given in this form, but of the latter kind only the lighter ones should be used, since heavy insoluble salts are apt to gradually subside in the soft mixture. Of other insoluble substances, volatile oils should first be rubbed with a portion of the sugar or an absorbent powder, and fixed oils be suspended in mucilage before they are incorporated.

If intended to be kept on hand, electuaries are made of such a consistence that they are rather soft, but at the same time sufficiently firm to prevent separation of the ingredients. For immediate use they are made somewhat softer, so that the mixture, when taken upon a spatula, will gradually drop off; they are then in a condition to be swallowed without mastication, and if partial separation should have occurred on standing, a uniform mixture is readily obtained by stirring.

If the main excipients of electuaries are pulps and honey, they will for a long time insure a proper consistence and prevent the preparation from becoming hard and dry. With sugar as the principal constituent, as in the case of conserves, the gradual evaporation of water will often cause the mass to become hard and the sugar to crystallize; the electuary should then be worked over, if necessary, with the addition of a little water or glycerin, but the substitution of common for refined sugar should not be resorted to.

CONFECTIO PIPERIS, *Br.*—Confection of Pepper.

Electuarium piperis.—Électuaire (Confection) de poivre, Fr.; *Pfefferlatwerge*, G.

Preparation.—Take of black pepper, in fine powder, 2 ounces; caraway fruit, in fine powder, 3 ounces; clarified honey, 15 ounces. Rub them well together in a mortar.—Br.

Action and Uses.—This preparation was introduced as a substitute for Ward's paste, and was employed as a remedy for anal fissure, hemorrhoids, and rectal ulcers. At present it is rarely used. The dose is from ½ to 1 drachm (2–4 Gm.) several times daily.

CONFECTIO ROSÆ, *U. S.*—Confection of Rose.

Confectio rosæ gallicæ, Br.; *Conserva rosarum.—Conserve de rose rouge*, Fr.; *Rosenconserve*, G.

Preparation.—Red rose, in No. 60 powder, 80 Gm.; sugar, in fine powder, 640 Gm.; clarified honey, 120 Gm.; stronger rose water, 160 Cc. Rub the red rose with the rose water heated to 65° C. (149° F.), then gradually add the sugar and honey, and beat the whole together until thoroughly mixed.—U. S.

Confection of rose may also be prepared of pharmacopœial strength by using—of red rose, in No. 60 powder, ½ avoirdupois ounce; sugar, 4 avoirdupois ounces; clarified honey, ¾ avoirdupois ounce; and stronger rose water, 1 fluidounce.

The British Pharmacopœia directs 1 pound of fresh red rose petals to be beaten in a stone mortar with 3 pounds of sugar.

The formula of the French Codex is similar to the first one, but omits the honey.

With a good quality of powdered red rose petals an excellent confection is obtained.

Pharmaceutical Uses.—It is used as an excipient in the official pills of aloes and iron, and is occasionally serviceable for the same purpose in extemporaneous pill-masses.

Action and Uses.—Confection of rose is used as an excipient in the preparation of pill-masses. Aside from the slight astringency due to the tannic acid in the rose, it is devoid of medicinal properties. It is never employed as a therapeutic agent.

CONFECTIO SENNÆ, *U. S., Br.*—Confection of Senna.

Electuarium e senna, P. G.; *Electuarium sennæ compositum, Electuarium lenitivum.—Lenitive electuary*, E.; *Electuaire de séné composé, Electuaire lénitif*, Fr.; *Sennalatwerge*, G.; *Elettuario lenitivo*, It.

Preparation.—Senna, in No. 60 powder, 100 Gm.; cassia fistula, bruised, 160 Gm.; tamarind, 100 Gm.; prune, sliced, 70 Gm.; fig, bruised, 120 Gm.; sugar, in fine powder, 555 Gm.; oil of coriander, 5 Gm.; water, a sufficient quantity to make 1000 Gm. Place the cassia fistula, tamarind, prune, and fig in a closed vessel with 500 Cc. of water and digest for 3 hours by means of a water-bath. Separate the coarser portions with the hand, and rub the pulpy mass, first through a coarse hair-sieve, and then through a muslin cloth. Mix the residue with 150 Cc. of water, and, having digested the mixture for a short time treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a water-bath, dissolve the sugar in the pulpy liquid, and evaporate the whole, in a tared vessel, until it weighs 895 Gm. Lastly, add the senna and the oil of coriander, and incorporate them thoroughly with the other ingredients while they are yet warm.—U. S.

The separation of the coarser portions with the hands is objectionable, and by no means necessary, for if the digestion be carried on on a boiling water-bath for 3 hours, with occasional stirring by means of a thick glass rod or a porcelain spatula, the pulpy mixture can easily be passed through a hair-sieve with the aid of a horn spatula.

It will be found advisable, instead of adding the oil directly with the senna to the pulp, to triturate it thoroughly first with about 50 Gm. of sugar, which should be reserved for that purpose out of the original quantity.

To make 10 avoirdupois ounces of confection of senna, the following quantities should be used: Senna, in No. 60 powder, 1 ounce; cassia fistula, bruised, 1 ounce and 263 grains; tamarind, 1 ounce; prune, sliced, 306 grains; fig, bruised, 1 ounce and 88 grains; sugar, 5½ ounces; oil of coriander, 23 minims; water a sufficient quantity. For the first treatment with water 5 fluidounces may be used, and for the second treatment 1¾ fluidounces. Before adding the senna and oil of coriander the pulpy mass should be evaporated to 9 avoirdupois ounces.

Take of senna, in fine powder, 7 ounces; coriander fruit, in fine powder, 3 ounces; figs, 12 ounces; tamarind, 9 ounces; cassia pulp, 9 ounces; prunes, 6 ounces; extract of licorice, 1 ounce; refined sugar, 30 ounces; distilled water, a sufficiency. Boil the figs and prunes gently with 24 ounces of distilled water in a covered vessel for 4 hours; then, having added more distilled water to make up the quantity to its original volume, mix the tamarind and cassia pulp, digest for 2 hours, and rub the softened pulp of the fruits through a hair-sieve, rejecting the seeds and other hard parts. To the pulped product add the sugar and extract of licorice, and dissolve them with gentle heat; while the mixture is still warm add to it gradually the mixed senna and coriander powders, and mix the whole thoroughly, making the weight of the resulting confection 75 ounces either by evaporation or by addition of more distilled water.—Br.

Mix powdered senna, 1 part; simple syrup, 4 parts; purified tamarind pulp, 5 parts, and warm by means of a steam-bath. It is greenish-brown.—P. G.

The last formula is the simplest, and yields a less pleasant but equally effectual preparation. That of the French Codex is of more complex composition.

Action and Uses.—This remedy is an agreeable laxative, and may be employed in habitual constipation and in persons suffering from hemorrhoids. The dose is from 1 to 2 drachms (4–8 Gm.), as required. (See EXTRACTUM SENNÆ FLUIDUM.)

CONFECTIO SULPHURIS, *Br.*—Confection of Sulphur.

Electuarium sulphuris.—Electuaire de soufre, Fr.; *Schwefellatwerge*, G.

Preparation.—Take of sublimed sulphur, 4 ounces; acid potassium tartrate, in powder, 1 ounce; tragacanth, in powder, 18 grains; syrup, 2 fluidounces; tincture of orange, ½ fluidounce; glycerin, 1½ fluidounces. Mix.—Br.

Action and Uses.—Confection of sulphur is a mild laxative, producing large semi-solid stools, and for this reason is well adapted for use as a laxative in cases suffering from hemorrhoids and anal fissure. The dose is from 1 to 2 drachms (4–8 Gm.).

CONIUM, *U. S.*—Conium.

Conii Fructus, Br.; *Fructus ("Semen") Conii; Poison hemlock, Hemlock fruit ("seed"), Poison or Spotted hemlock or parsley, St. Bennett's herb, Spotted cowbane*, E.; *Schierling, Gefleckter Schierling*, G.; *Grand ciguë, Ciguë officinale*, Fr.; *Cicuta Maggiore*, It.; *Cicuta mayor*, Sp.; *Sementes de Cicuta*, Port.

The full-grown, but unripe, fruit of *Conium maculatum* L. (Fam. *Umbelliferæ*), carefully dried and preserved, and yielding, when assayed by the U. S. P. process, not less than 0.5 per cent. of coniine. After being kept for more than two years conium is unfit for use.

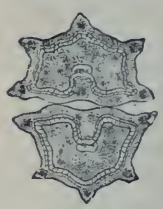
Conium is official in all pharmacopœias. The names "*Cicuta major* Lam." used by the Sp. P., and "*Cicuta maculata* Lam." used by the Port. P., are not synonyms in the true sense, but confusions of the ancient name, which was Cicuta, with Conium, which latter is authoritative under the rules of botanical nomenclature. In several pharmacopœias, notably the British, the herb or leaves are also official, the Br. P. requiring that the herb be collected when the fruit is beginning to form.

Origin.—The hemlock plant is a tall, erect-branched, white-flowered biennial (Fig. 138), native of the temperate regions of Europe and Asia, and extensively naturalized in

FIG. 138.

Conium (⅓ Nat.).

FIG. 139.



Conium; transverse section (× 8).

FIG. 140.

Conium fruit (× 6).

similar regions of both the north- and south-temperate zones. Both wild and cultivated plants contribute to the commercial drug, and it is not certain which, if either, is superior.

Its use, both as a medicine and a poison, is of great antiquity, it being the poison hemlock which furnished the death-draught of Socrates. The herb has been determined (see *Constituents*) as richest when in full bloom; the fruit, at the time specified in our definition.

Description.—Greenish-gray-brown, and about 3 Mm. ($\frac{1}{8}$ In.) long; consisting of 2 (usually separated) carpels, each about 1.5 Mm. ($\frac{1}{16}$ In.) broad, ovoid, somewhat curved, the inner and flattened side marked by a deep longitudinal groove, or by a line overlying such a groove, the outer, convex side bearing 5 pale-yellow, thin, sharp, somewhat crenate ribs, the intervening surfaces wrinkled, but otherwise smooth; pericarp without oil-tubes; odor slight, mousey, disagreeable, greatly increased by soaking in water, especially if a little potassium or sodium hydroxide be added; taste slight, at length somewhat acrid.

Although there are many umbelliferous fruits (see UMBELLIFERÆ) which bear some superficial resemblance to conium, there is none which possesses the combination of characters found in our description. The drug is scarcely subject to adulteration, though substitution sometimes occurs through carelessness (see also ANISUM).

THE HERB (*Conii Folia*, Br.; *Herba Conii*, P. G.).—The characters of the herb are best indicated by the accompanying cut. The color of the leaves, *including their tips*, is a pale and dull or gray-green, and the entire plant is quite smooth. It has the peculiar odor-character described under the fruit. No other herb having its general appearance, with involucres to both umbels and umbellules, shares these characters. Anthriscus and Æthusa (*Fool's parsley, Small hemlock*, E.; *Hundspetersilie, Gartenschierling*, G.; *Ethuse, Petite cigue, Ache des chiens*, Fr.) have been confused, but the former is hairy, while the latter has somewhat shining leaves and its primary umbels are without involucres.

Constituents.—Both the nature and the amount of the active constituents of conium, especially of the herb, are still subject to contradictory statements. Considering first the fruit, we find that its important active constituents are *coniine*, or "conine" (cynapine?) ($C_8H_{17}N$), separately considered below, and *conhydrine* or *oxyconiine* ($C_8H_{17}NO$), which occurs in iridescent scales, has a slight odor of coniine, is soluble in alcohol, ether, and chloroform, and slightly in water, melts at 118° to 122° C. (244.4°–251.6° F.) and boils at 220° to 225° C. (428°–437° F.). A sample of fruits selected individually is said to have yielded more than 3 per cent. of coniine, but owing to the impossibility of securing all of them, in bulk, in exactly that stage of development, the commercial drug yields but from 0.5 to 1.5 per cent., and is extremely irregular, according to the proportion of fruits which are in just the proper condition. Three other alkaloids, present in small amount, are as follows: *pseudoconhydrine*, isomer of conhydrine, in needle-like crystals, soluble in water as well as in alcohol, ether, and chloroform, melting at 98° C. (208.4° F.) and boiling at 230° to 233° C. (446°–451.4° F.); *methylconiine* ($C_9H_{19}N$), and *ethyl-piperidine* ($C_7H_{15}N$). In addition, the fruit contains a fixed oil, a minute portion of non-poisonous volatile oil having the odor of cumin, and probably malic acid (coniic acid) combined with the alkaloids.

Statements concerning the constituents of the herb are most widely at variance. Farr and Wright reported that, when in full flower, the stem contains 0.064 per cent., the leaves 0.187 per cent., and the flowers and flower-stalks 0.236 per cent. of total alkaloid, but other analysts have reported much less. The root is said to contain 0.018 to 0.047 per cent., but the variation would perhaps be much greater if assayed at all the different stages of development.

The Pharmacopœia requires that conium, when assayed by the process given below, shall yield not less than 0.5 per cent. of coniine;

Assay of Conium.—Conium, in No. 60 powder, 10 Gm.; ether, alcohol, ammonia-water, normal sulphuric acid, sodium carbonate test-solution, distilled water, hydrochloric acid (5 per cent. solution), of each, a sufficient quantity. Place the conium in a 200-Cc. Erlenmeyer flask, add 100 Cc. of a mixture of ether 98 parts, alcohol 8 parts, and ammonia-water 3 parts, all by volume, insert the stopper securely, and shake the flask at intervals during 4 hours. After the powder has settled, decant 50 Cc. of the clear liquid into a beaker and add sufficient normal sulphuric acid to produce a distinctly acid reaction. Evaporate the ether at a gentle heat by the aid of a water-bath; then add 15 Cc. of alcohol, and set the beaker aside in a cool place for 2 hours to allow the ammonium sulphate to deposit. Filter the liquid; wash the residue and filter with a little alcohol, and add the washings to the filtrate; neutralize any excessive amount of acid with sodium carbonate test-soluion,

being careful to retain a slight acidity. Concentrate the liquid to 3 Cc. by the aid of a gentle heat on a water-bath, add 3 Cc. of distilled water and 2 drops of normal sulphuric acid. Add 15 Cc. of ether to remove traces of fatty matter, pour off the ether solution and repeat the washing with 15 Cc. of ether. Then transfer the acid liquid to a separator, introduce a small piece of red litmus-paper, and add sufficient sodium-carbonate test-solution to render the liquid slightly alkaline; then shake out with successive portions of 15, 15, and 10 Cc. of ether. To the combined ether solutions, in a tared beaker, add, drop by drop, sufficient hydrochloric acid (5 per cent. solution) to insure an excess of acid, and then evaporate the ether by a gentle heat on a water-bath. Remove the excess of hydrochloric acid by adding to the residue 3 Cc. of alcohol, and heating gently to evaporate the liquid, repeat this operation once, and dry the residue at a temperature not exceeding 60° C. (140° F.) until the weight, after cooling in a desiccator remains constant. The weight of the residue multiplied by 0.777, and this product by 20, gives the percentage of coniine contained in the conium.—U. S.

Coniine.—*Coniine*, E.; *Koniin*, G. $C_8H_{17}N$.—This, the most important constituent of conium, was discovered by Giesecke in 1827, but its true nature as an alkaloid was not determined until 1831 by Geiger. It occurs in all parts of the plant, but chiefly in the immature fruit, in combination with malic acid. Coniine may be obtained by adding potassium or sodium hydroxide to the crushed fruit and subjecting the mixture to distillation on a steam-bath. The resulting distillate is neutralized with hydrochloric or sulphuric acid, evaporated to dryness, and the alkaloidal salt extracted by means of ether or alcohol, which removes ammonia. By adding potassium hydroxide to the alkaloidal salt the base is liberated, and can be extracted with ether, to be finally purified by distillation in a current of hydrogen.

Pure coniine occurs as a colorless, almost odorless liquid, having a specific gravity of 0.8438 at 19° C. (66.2° F.), and boiling at 165.8° C. (330.44° F.). In the cold it congeals to a crystalline mass, which melts at —2° C. (28.4° F.). Coniine is soluble in 90 parts of water, the saturated solution becoming turbid on warming. On the other hand, coniine is capable of taking up 25 per cent. of water. It has an alkaline reaction, and is readily oxidized upon exposure to air, assuming a brownish color.

Commercial coniine is usually contaminated with conicein, as much as 70 per cent. having been found by Wolffenstein, from which it may be freed by treating the hydrochloride with acetone, in which coniine hydrochloride is sparingly soluble, whereas the conicein salt is readily soluble. It is a yellowish liquid having a rather disagreeable odor.

Concentrated sulphuric acid colors coniine blood-red, the color gradually changing to green. Potassium-cadmium iodide causes an amorphous precipitate in solution of coniine, which distinguishes the latter from nicotine, yielding a crystalline precipitate. Dilute solutions of nicotine are precipitated by aqueous solutions of platinic chloride, while those of coniine are not.

Chemically, coniine may be looked upon as hexahydropropylpyridine, $C_5H_9.NH.C_3H_7$. Its constitution was established by Hoffmann in 1881, and its synthetic production accomplished by Ladenburg in 1886.

The salts of coniine are readily soluble in water, moderately so in alcohol and mixtures of alcohol and ether, and insoluble in ether. Aqueous solutions of the salts cannot be concentrated in air without decomposition. The most important salt of coniine is the hydrochloride, $C_8H_{17}N.HCl$, which may be obtained from an aqueous solution in large rhombic crystals, permanent in air and melting at 220° C. (428° F.).

Pharmaceutical Preparations.—Fluidextract of Conium, U. S. P.; Tincture of Conium, Br. P.

Action and Uses.—All the preparations made from the fruit, the juice from the leaves, and the alkaloid obtained from both fruit and leaves, have identical physiological actions, and may be employed interchangeably. When taken in full dose, conium produces muscular relaxation followed by loss of power. When the amount ingested is sufficiently large, it produces vertigo, staggering, disordered vision, and circulatory depression. Poisonous amounts, in addition to the above symptoms, cause dilatation of the pupils, ptosis, partial aphonia, and complete muscular paralysis. Conium exerts its dominant influence upon the motor nerves, which are greatly depressed. Full doses slightly depress the sensory nerves and the spinal cord, but the cerebrum is not affected, as consciousness

is retained almost until death occurs when lethal doses are given. Respiration is depressed because of the paralyzing action of the drug upon the motor nerves supplying the respiratory muscles. Its dominant action upon the circulation is that of a depressant; blood-pressure is at first decreased, but later it is increased, because of the asphyxia resulting from respiratory failure. The treatment of conium-poisoning consists in the early removal of the drug by the stomach-tube, and the administration of respiratory and nervous stimulants, such as strychnine. Cardiac stimulants should be given when needed, and artificial respiration may be resorted to.

The drug has been recommended as an antispasmodic, anaphrodisiac, diuretic, and anodyne. Formerly it was employed in many conditions, but at present its field of usefulness has become greatly limited. It was thought to be of value in the treatment of epilepsy, tetanus, chorea, laryngismus stridulus, and other spasmodic conditions. It has been recommended in mania, melancholia, glandular enlargements, engorgement of the liver, and cardiac palpitation, but is rarely employed for any of these conditions. A lotion containing 1 to 4 minims (0.05–0.25 Cc.) of the alkaloid in 1 ounce (30 Cc.) of water or very dilute alcohol, has been tried in scrofulous ophthalmia with asserted success. A plaster containing hemlock, especially when combined with belladonna, is sometimes beneficial in the treatment of intercostal neuralgia; and an ointment containing 10 per cent. of the extract sometimes does good in anal fissure and hemorrhoids. The drug when spread over the surface of a poultice relieves the pain of cancers and ulcers, and should be tried in these conditions. It is of value in spasm due to irritation of a nerve-trunk, and coniine when injected hypodermically frequently affords relief.

The fluidextract is probably the best preparation to employ. Because of the unreliability of the drug, it should always be given in small doses at first, and increased until its effects are produced. The dose of the fluidextract is from 2 to 6 minims (0.10–0.40 Cc.). The dose of the powdered leaves is from 2 to 6 grains (0.12–0.40 Gm.); of the extract, from ½ to 1 grain (0.03–0.06 Gm.). Coniine hydrochloride is given in doses of from ⅛ to 1 grain (0.008–0.06 Gm.), but the latter amount should be given cautiously.

Allied Plants (see also UMBELLIFERÆ).—The genus *Conium* contains one other species, native of Africa, the properties of which have not been investigated. The closely related genus *Cicuta* L. should be here considered. Authors are not agreed as to the number of its several species, some of them being classed as varieties. The two of importance are the *C. virosa* L. (*Cicutaria aquatica* Lam.), of northern Europe and Asia (the European *Wild* or *Water hemlock* or *cowbane*, *Wild* or *Spotted parsley* or *parsnip*, *Brook-tongue*, *Death-in*, *Wasser-Schierling*, *Giftwütherich*, *Cigue vireuse*, *Cicuta virulenta*), and the *C. maculata* L. (*C. virosa maculata* Coulter et Rose), the American *Wild* or *Water hemlock* or *cowbane*, *Beaver* or *Muskrat poison*, *Children's death*, etc. Both species are used to some extent in medicine, and both are responsible yearly for cases of fatal poisoning, chiefly of children. The stem, which has a not unpleasant odor, is mistaken for angelica, and the highly attractive fleshy roots for Jerusalem artichokes or other edible tubers. The latter species, which especially interests us, is one of our commonest swamp-weeds, growing abundantly along streams, ponds, ditches, and wet meadows throughout the eastern and central portions of the United States. It has a thick, hollow, glaucous-purple, somewhat spotted stem, which sometimes reaches a height of 5 feet and branches strongly, the ascending branches terminating in large umbels of white flowers. Its character and appearance are best learned from Fig. 141. Coniine and *cicutine* have been reported. The important active constituent appears to be *cicutoxin*, an amorphous, tenacious, non-drying, resinous substance, occurring in bright-yellow drops, soluble in alcohol, ether, chloroform, alkalies, and hot water. It is said not to be present in the fruit, where it is replaced by the volatile alkaloid *cicutine* (which may be identical with coniine), but is present in the resinous cortical zone of the rhizome to the extent of 3.5 per cent., and almost certainly in the stem and herbage. The fruit contains about 1 per cent. of a volatile oil, said to be practically identical with that of cumin. Several other species are poisonous to stock, and doubtless contain the same constituents.

In some parts of Europe, especially England, *Œnanthe crocata* L., the *Water dropwort* or *Dead tongue*, also called *Water hemlock*, plays a similar rôle to that of the cicuta in America. Holmes reports it as the most poisonous and dangerous of all native English plants. The symptoms of poisoning are very similar to those caused by cicuta, and the active constituent is very likely identical. The plant produces a fascicle of fleshy thickened roots very much like those of cicuta, although somewhat more slender and more tapering, and contains a similar yellow, resinous, acrid juice. The leaf and fruit characters are indicated in Fig. 142, *a*, *b*, *c*.

Fig. 141.

Cicuta maculata (½ Nat.).

Fig. 142.

Œnanthe crocata: *a*, segment of lower leaf; *b*, of upper; *c*, fruit (*a* and *b*, ½ Nat.; *c*, enlarged). (After Holmes.)

Several species of the genus *Sium* L. are also known as *Water parsnip*, and are poisonous. They appear to contain a constituent very similar, if not identical, with that of cicuta.

CONVALLARIA, *U. S.*—Convallaria.

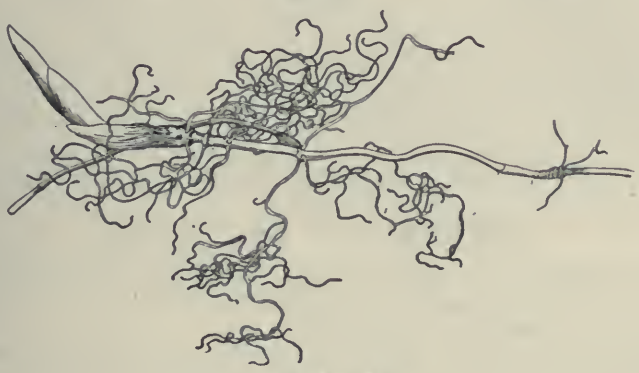
Lilium convallium.—*Lily of the valley*, E.; *Maiblumen*, G.; *Muguet*, Fr.; *Mughetto*, It.; *Liris de los valles*, Sp.

The dried rhizome and roots of *Convallaria majalis* L. (*C. latifolia* Lam.—Fam. *Liliaceæ*).—U. S.

Convallaria is official in several other pharmacopœias in the form of the entire plant or of the flowers only.

Origin.—This well-known garden-flower is a native of Europe and northern Asia. The plant which is native of our southern Alleghenies, is not recognized as distinct, though it seems difficult to believe that it can be the same. The latter is collected to some extent, but its contribution to commerce is unimportant. Lily of the valley should not be confounded with Solomon's seal, which was once known as *Convallaria multiflora.*

FIG. 143.



Convallaria (¾ Nat.).

Description.—Rhizome of horizontal growth and somewhat branched; length indefinite, the internodes mostly about 5 Cm. (2 In.) long, 1 to 3 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ In.) thick, cylindrical, whitish or pale-brown, bearing few circular scars, and at each joint a circle of 8 or 10 long, thin, wavy, branched, brown roots; fracture somewhat gummy and fibrous, white; odor peculiar, pleasant; gummy on chewing, the taste sweetish and bitterish, then somewhat acrid. No other drug is to be mistaken for it.

Constituents.—The rhizome yields 0.6 per cent. of the bitter-sweet, white, somewhat crystalline glucoside *convallamarin* ($C_{23}H_{44}O_{12}$). It is soluble in water and alcohol, insoluble in ether and chloroform, is precipitated by tannin, and with dilute acids splits up into glucose and *convallamaretin.* Convallarin ($C_{34}H_{62}O_{11}$) is an acrid glucoside crystallizing in rectangular prisms, soluble in alcohol, insoluble in ether, and sparingly soluble in water, but foaming with it like saponin. On boiling with dilute acids it forms sugar and *convallaretin.* The odorous principle of the flowers forms volatile crystals which are fragrant in dilute solution. The rhizome is reported to contain about three times as much active constituent as the stems and flowers.

Pharmaceutical Preparations.—FLUIDEXTRACT OF CONVALLARIA FLOWERS, N. F.; FLUIDEXTRACT OF CONVALLARIA, U. S. P.

Action and Uses.—Convallaria has been employed as a substitute for digitalis. While it is less powerful than digitalis, in certain cases it seems much more efficient than the latter remedy. It was first used in medicine in the treatment of dropsy, as its administration augments the flow of the urine. When given in full dose, it sometimes produces nausea and vomiting, and by increasing the peristaltic action of the intestines causes some laxity of the bowels. When given in proper amount, it strengthens the contraction of the heart muscle, reduces the number of heart-beats, increases blood-pressure, stimulates the respiratory function, and frequently increases the appetite and aids digestion. Poisonous amounts act as a depressant, disturbing respiration and paralyzing the heart, sometimes in diastole, at others in systole. The emetic properties of the drug are probably due either to its acrid resin or to its glucoside, convallarin. Convallamarin is the active principle which produces the favorable changes in the circulation Convallaria may be employed in cardiac dropsy and in all of those conditions in which digitalis is beneficial (see DIGITALIS); but it is probably most useful in cases of arhythmia and cardiac hurry. The dose of the fluidextract is from 4 to 8 minims (0.25–0.50 Cc.), 3 times daily. A tincture may be given in doses of from 5 to 20 minims (0.3–1.30 Cc.), and an aqueous extract of the whole plant has been given in doses of from 15 to 20 grains (1–1.30 Gm.) daily. The dose of convallamarin is $\frac{1}{2}$ grain (0.03 Gm.), 3 times daily.

Allied Drugs.—The rhizomes of various species of *Polygonatum* Adans., of the same family, are largely used under the name *Solomon's seal*. *P. multiflorum* (L.) All. (*Convallaria m.* L.) and *P. officinale* (L.) All. (*Convallaria o.* L.; *C. Polygonatum* L.; *P. vulgare* Desf.) yield the European Solomon's seal (*Ladies' seal, David's harp, Ladder to heaven* (*Scala Cœli*), *Whitewort, Weisswurzel, Salomon-Siegel, Fraxinelle, Sceau de Salomon, Genouillet*). *P. biflorum* (Walt.) Ell. (*Convallaria b.* Walt.) and *P. commutatum* (R. et S.) Dietr. (*Convallaria c.* R. et S.; *P. gigantenum* Dietr.) yield the American variety. *Vagnera racemosa* (L.) Morong (*Convallaria r.* L.; *Smilacina r.* Desf.) yields the American *False Solomon's seal*. All these rhizomes, nearly bare of roots, have the following general characters: They occur of irregular length, up to about a foot, are more or less crooked, occasionally branched, 1 Cm. (about ½ In.) or less in thickness, more or less flattened from above, irregularly transversely wrinkled or ridged, yellow or yellowish-white, smoothish and usually somewhat shining, and bearing very large, shallow-stem-scars on the upper surface, these either depressed or slightly elevated. The fracture is short, somewhat waxy, yellowish. There is little odor, and the taste is gummy or mucilaginous, sweetish and bitter, afterward somewhat acrid. The constituents are very similar to those of convallaria, convallarin being the important one.

COPAIBA, *U. S., Br.*—Copaiba.

Balsamum copaïvæ, P. G.—*B. Copaiferarum.*—*Balsam copaiva, Balsam capivi*, E.; *Copaivabalsam*, G.; *Oleo-resine (Baume) de copahu*, Fr., It.; *Balsamo di copaive*, It., Sp.; *Terebinthinia Copahiba, Oleo de Copaiba*, Port.

The oleoresin of one or more South American species of *Copaiba* Mill. (*Capaifera* L.—Fam. *Leguminosæ*).

Copaiba is official in all pharmacopœias.

Origin.—The genus *Copaiba* Mill. comprises some 12 species of tropical America, besides about 4 African species. The former yield our commercial supplies. They are handsome trees, with pinnate leaves and panicles of bean-like flowers. Some of them are very large, and their timber is highly prized for its great strength, hardness, toughness, and durability. It is largely used for the keels of river-boats and for wheels, as well as for cabinet-work. The cotyledons of some species become very hard, like vegetable ivory, and are used like that substance in the manufacture of small objects (for an account of coumarin-yielding seeds, see DIPTERYX). Not all of the species have been examined as to their production of copaiba, but it is likely that most of them produce it. The following are known to yield commercial supplies: In Brazil, *C. Langsdorffii* (Desf.) Kuntze, *C. confertiflora* (Benth.) Kuntze, *C. coriacea* (Mart.) Kuntze, *C. oblongifolia* (Mart.) Kuntze; in and northwest of the Orinoco Valley *C. officinalis* Jacq.; in the Amazonian region, *C. Guianensis* (Desf.) Kuntze, and *C. multijuga* (Hayne) Kuntze. These products differ considerably in their appearance, composition, and value, giving us different geographical varieties or grades, but it is not definitely known from which species all of these grades are respectively derived. The liquid, often incorrectly termed "balsam," collects in cavities of the trunk as a pathogenic product, doubtless as an antiseptic protective provision by the plant. It exists abundantly, however, in schizogenous ducts in the secondary wood. The cavities are of all sizes, often extending through a great part of the length of the trunk and containing many gallons. The pressure exerted by these columns of liquid sometimes bursts the trunks. Collection is made by boring or cutting through the heart of the tree, when the copaiba often spurts out with great violence, requiring special provisions for avoiding loss. It is said that trees which will not yield copaiba at once may do so after a time if the cavity thus made is plugged up.

Adulteration.—The variable conditions of commercial copaiba, depending on its origin from different species, renders the detection of adulteration by no means an easy task. This well-known fact has greatly encouraged fraudulent operations, which are, in fact, so common that adulterated copaiba has long been the rule rather than the exception. One of the commonest methods of fraud is the abstraction of a part of the volatile oil. This treatment increases the relative amount of resin and, like the addition of foreign resins, is provided for in the official tests. The presence of other volatile oils and turpentines usually becomes quite evident by the different odors on slowly heating a little of the copaiba.

The ordinary adulterants of copaiba are fixed oils, paraffin, and gurjun balsam, the detection of which is provided for in the following official description and tests:

Properties and Tests.—A pale-yellow to brownish-yellow, more or less transparent

and viscid liquid, sometimes fluorescent; having a peculiar, aromatic odor and a persistent, bitter, and acrid taste.

Specific gravity, 0.950 to 0.995 at 25° C. (77° F.).

Insoluble in water, soluble, or showing at most a slight opalescence, in absolute alcohol, carbon disulphide, petroleum benzin, and in fixed and volatile oils, completely soluble in chloroform and ether.

When heated on a water-bath, it should evolve no odor of turpentine, and after 48 hours should leave a resinous mass weighing not less than 50 per cent. of its original weight.

1 Gm. of copaiba, when dissolved in 50 Cc. of alcohol, should require not less than 2.3 Cc., and not more than 2.8 Cc. of half-normal alcoholic potassium hydroxide for neutralization, using 1 Cc. of the phenolphthalein test-solution as indicator (presence of a normal proportion of acid resin).

When 4 drops of nitric acid (specific gravity 1.40) and 1 Cc. of glacial acetic acid are mixed in a test-tube, and 4 drops of copaiba are carefully poured on top of the liquid, no reddish zone should appear, nor should the fluid assume a red or purple color after being shaken (absence of gurjun balsam).

If 5 Cc. of copaiba be shaken with 15 Cc. of alcohol, and heated to boiling for 1 minute, no drops of oil should separate after cooling and standing for an hour (absence of paraffin oils).

If 20 drops of copaiba be boiled with 1 Cc. of an alcoholic potassium-hydroxide solution (1 in 10) for 2 minutes and cooled, and then twice its volume of ether be added to the liquid, no gelatinization should occur (absence of fixed oils).

If 1 Gm. of copaiba be shaken with 10 Cc. of ammonia-water in a stoppered vial, and allowed to stand for 24 hours, the liquid will become turbid, but it should not gelatinize, nor should a firm mass be formed (limit of resin).—U. S.

Constituents.—The acrid and bitter taste of copaiba is due to the resin and a bitter principle. The amount of oil (see Oleum Copaibæ) varies from 30 to 60 per cent., or even above 80 per cent., and on driving it off by evaporation a hard brittle mixture of acid resins is left. Copaiba, on long standing, will deposit prismatic soft crystals of copaivic acid ($C_{20}H_{32}O_2$), which are soluble in alcohol, ether, and fixed and volatile oils. The Para variety has a similar deposit of oxycopaivic acid ($C_{20}H_{28}O_3$), and the Maracaibo variety deposits metacopaivic acid ($C_{22}H_{34}O_4$). On keeping, copaiba gradually becomes thicker, through conversion of the volatile oil into a soft resinous body.

Varieties.—The different kinds of copaiba are commercially named from the places of export, but even as obtained from the same places they are not always identical in every particular. *Para copaiba* is the most limpid and the lightest-colored kind, and frequently contains from 65 to 85 per cent. of volatile oil. *Maranham copaiba* is a little denser, has about the consistence of olive oil, differs somewhat in odor from the preceding, and contains from 40 to 50 per cent. of volatile oil. *Rio Janeiro copaiba* resembles the last. These Brazilian copaibas yield, with one-third to one-half their weight of ammonia, compounds which form perfectly clear solutions in the volatile oils contained in them; but in the presence of a fixed oil clear solutions are not obtained. *Surinam copaiba*, chiefly from *C. Guianensis*, is also one of the thinner and lighter yellow sorts, containing, in a sample examined by Pool, 78 per cent. of oil. This variety is freely soluble in ether and chloroform, and in 4 to 5 parts of absolute alcohol, with an equal portion of which it forms a turbid mixture. It gives a violet color with a solution of 1 part of bromine in 20 of chloroform. *Maracaibo copaiva* is the thickest variety, usually of a dark-yellow color and not quite transparent. It contains less volatile oil, and does not always yield a clear mixture with a little ammonia water; but it solidifies readily with magnesia, and is well adapted for making the official Massa Copaibæ. According to the German Pharmacopœia, thick copaivas are to be preferred.

Pharmaceutical Preparations.—Compound Copaiba Mixture, N. F.; Chapman's Mixture, N. F.; Lafayette Mixture, N. F.

Action and Uses.—Copaiba is a mild stimulant, laxative, and diuretic. When taken in moderate amount, it produces a sensation of warmth throughout the gastro-intestinal tract and acts as a stimulant upon the pulmonary and genito-urinary mucous membranes. It is eliminated by the kidneys, giving the urine a peculiar odor; by the pulmonary mucosa, imparting a characteristic smell to the breath; and by the skin, sometimes causing an eruption like measles or one closely resembling that seen in secondary

syphilis. Overdoses produce nausea, vomiting, purging, and hæmaturia, and if the urine be examined with nitric acid after the ingestion of this drug, a precipitate is formed which may be mistaken for albumin.

Copaiba is regarded as a stimulant to mucous membranes, especially of the genito-urinary tract, and is usually employed in subacute and chronic conditions. The drug is contraindicated in acute sthenic inflammations, but may be employed with asserted success during the stage of depression which invariably follows them. It is one of the best drugs we possess in the treatment of specific urethritis of a subacute or chronic type, and may be employed in chronic cystitis resulting from gonorrhœa. It has also met with favor in the treatment of subacute and chronic bronchitis, and has been recommended in leucorrhœa, vaginal gonorrhœa, subacute and chronic pyelitis, chronic dysentery, diarrhœa, and hemorrhoids. In dropsy resulting from slow renal changes and in that accompanying cirrhosis of the liver it may be of benefit. Copaiba has been locally applied to ulcers, chilblains, cracked nipples, anal and other fissures, with fairly good success, but at present it is rarely employed for these conditions.

The dose of copaiba is from 15 minims to 1 fluidrachm (1–4 Cc.), 3 times daily; or it may be given in smaller amounts more frequently repeated. It is usually administered in gelatin capsules, but may be given in the form of an emulsion made with yolk of eggs or with acacia. Equal parts of liquor potassæ and copaiba make a perfect solution which may be diluted and flavored as desired. The volatile oil is employed in doses of from 5 to 15 minims (0.3–1 Cc.), and the resin in doses of from 5 to 20 grains (0.30–1.3 Gm.).

Copal varnish has been applied locally to abort felons; but at present it is rarely employed.

Gurjun balsam has been given as a substitute for copaiba in the various conditions in which the latter remedy has proved efficacious.

Allied Products.—An *African copaiba* has occasionally appeared which shows some resemblance to the genuine article. It varies greatly in appearance and properties, so that no characteristic description of it is possible. A specimen examined by Umney, containing 39 per cent. of oil, had a specific gravity of 0.9185 at 16° C. (60.8° F.). It dissolved in its own weight of petroleum ether, in 3 parts of ether, and in 7 of glacial acetic acid, but not completely in 50 parts of absolute alcohol. The blue oil fractionated from its oil in a perfectly dry state, agreed with that from Maracaibo copaiba. African copaiva is reported as being less unpleasant to take than the ordinary kind, and to be active, though less so than the other. Peckolt states that the pods of *C. nitida* Mart., which has black seeds, contain nearly 20 per cent. of a soft resin having the odor of copaiba, and are successfully used by Brazilian herbalists in the treatment of gonorrhœa.

Hardwickia pinnata Roxb. (Fam. *Leguminosæ*) is a large East Indian tree, yielding from incisions a thick, dark-brown oleoresin, which in thin layers is greenish or wine-red, transparent but not fluorescent, and resembles copaiba in both odor and taste. Broughton (1872) obtained from it between 25 and 40 per cent. of volatile oil having the composition $C_{10}H_{16}$, the remainder consisting of several resins, but copaivic acid was not obtained.

Dipterocarpus alatus Roxb., *D. turbinatus* Gærtn. (*D. lævis* Ham.), *D. incanus*, Roxb. (*D. costatus* Gærtn.), and several other species of the same genus (Fam. *Dipterocarpaceæ*) which are indigenous to various parts of India, the East Indian and the Philippine Islands, yield *gurjun balsam* or *wood-oil*, obtained by cutting large holes into the lower part of the stem and charring the wood, after which the oleoresin flows abundantly. It is a viscid liquid, varying in color from greenish-gray to brownish, opaque in reflected light, but transparent and of a dark-brownish or reddish tint when viewed in transmitted light; its odor is similar to but weaker than that of copaiba, and its taste is more bitter and somewhat aromatic, but not acrid. It is freely soluble in chloroform, carbon disulphide, and volatile oils, but only partly soluble in alcohol, fusel oil, ether, and petroleum benzin. When strongly agitated with water, gradually added until 5 parts have been used, gurjun balsam furnishes a very thick emulsion, which does not become clear on warming, but on the addition of the same bulk of water the balsam separates, and the clear watery liquid has a bitter taste and an acid reaction (Flückiger). When heated in a stoppered vial to near 130° C. (266° F.) it has the curious property of becoming gelatinous, the fluidity not being restored on cooling. The amount of volatile oil present in gurjun balsam varies considerably: Werner (1862) obtained 16 per cent., Flückiger 45.5 per cent., and from one specimen even 72 per cent.; it is strongly lævogyre, and has the composition $C_{15}H_{24}$, the density 0.9044 to 0.918 at 15° C. (59° F.), and the boiling-point at 255° C. (491° F.). The resin left after distillation of the volatile oil yields to caustic potassa *gurjunic acid*, $C_{22}H_{34}O_4$, which may be obtained pure by adding to the potassa solution an excess of ammonium chloride, filtering, and decomposing with hydrochloric acid. Gurjunic acid dissolves readily

in ether and strong alcohol, slowly in benzene, and with difficulty in carbon disulphide; it melts at 220° C. (418° F.), and congeals again at 180° C. (356° F.). A crystalline neutral resin of gurjun balsam, which had been sold as copaivic acid, was found by Flückiger (1878) to have the composition $C_{28}H_{46}O_2$, to melt at 126° C. (258.8° F.), and to dissolve in sulphuric acid with an orange color.

Lagam Balsam, *Minjak-lagam*, comes from an unknown tree in Sumatra, and closely resembles gurjun balsam. Examined by Haussner (1883), it was dingy-green in reflected and yellowish-transparent in transmitted light, had a bitterish and lastingly acrid taste, and was completely soluble in alcohol, ether, benzene, chloroform, and carbon disulphide; it yields about 33 per cent. of lævogyre volatile oil of the composition $C_{20}H_{32}$, and boils at about 250° C. (482° F.). The acid resin is uncrystallizable, and has the composition $C_7H_{14}O_3$; the neutral resin, fused with potassa, yields phenols and formic, acetic, butyric, and aromatic acids.

CORIANDRUM, *U. S.*—Coriander.

Coriandri fructus, Br.—*Coriander-fruit* ("*seed*"), E.; *Koriander*, G.; *Coriandre*, Fr.; *Cilantro*, *Culantro*, Sp.; *Coentro*, Port.; *Semina Coriandri*, Dan.

The dried ripe fruit of *Coriandrum sativum* L. (Fam. *Umbelliferæ*).

Fig. 144.

Coriandrum: fruit and longitudinal section, magnified 3 diameters; transverse section, magnified 8 diameters.

Origin.—A smooth, branching annual, native of Asia, very widely and extensively cultivated for its fruit, and naturalized in many temperate and warm-temperate regions. It has decompound leaves and compound naked umbels of white or rose-colored flowers. It emits an offensive odor of bedbugs, whence its name. This statement is especially true of the young plant, and pertains also to the young fruit. In that condition the fruit yields a very small amount of volatile oil, which also partakes of this odor. Russia produces the bulk of the crop. The earliest is from Morocco, being marketed in London in July and August, a month or two ahead of the Russian.

Description.—Of 2 united carpels; globular, 4 to 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ In.) in diameter, pale brownish-yellow, bearing 5 short calyx-teeth and a short stylopodium; each carpel bears 5 indistinct wavy ribs and 4 more prominent filiform ones, their interspaces nearly smooth; pericarp with 2 oil-tubes upon the inner, more or less concave side; odor and taste aromatic, mild, and pleasant.

Indian coriander constitutes a distinct commercial variety, recognized by its ovoid form.

Constituents.—Trommsdorff obtained from coriander nearly 0.5 per cent. of volatile oil (see Oleum Coriandri), and 13 per cent. of fatty matter, besides a small amount of mucilage, malic acid, and traces of tannin.

Action and Uses.—Coriander is a mild stimulant and aromatic. It is rarely employed in medicine alone, but is combined with other remedies either to aid in their absorption or to render them more agreeable to the taste. The drug is used by the laity as a condiment, and is believed to aid in the digestion of pastry. The dose is from 20 grains to 1 drachm (1.3–4 Gm.).

CORNUS.—Cornus.

Dogwood, Flowering, American, Virginia, or Florida dogwood bark, New England, American, or False boxwood, Flowering or White cornel, E.; *Grossblütige Kornel, Hornbaum*, G.; *Cornouiller a grandes fleurs*, F.

The dried bark of the root of *Cornus florida* L. (Fam. *Cornaceæ*).

Origin.—A small and beautiful tree of the eastern United States, valued for its ornamental properties and for its hard and fine-grained wood, used to substitute boxwood, as well as for its medicinal properties. The showy inflorescence, commonly mistaken for the flower, with its 4 large white or purplish (in one variety rose-colored) bracts, here figured, has similar properties to those of the bark, and is much used in country practice, steeped in gin or other spirit. The red drupaceous fruits are also used.

Description.—In short quilled pieces or irregular curved chip-like fragments, rarely exceeding 5 Cm. (2 In.) in any direction and 1 to 4 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ In.) thick; externally of a dirty-brown color, thinly and lightly fissured, sometimes thinly scaly, usually with a few short, transverse ridges, or, if the corky layer has been removed, reddish and without fissures or ridges; inner surface red-purple, with very numerous short, broad striæ, and somewhat

harsh to the touch; fracture short, light purple in the inner layer, otherwise whitish, with yellow striæ of stone-cells; nearly odorless, astringent, and bitter.

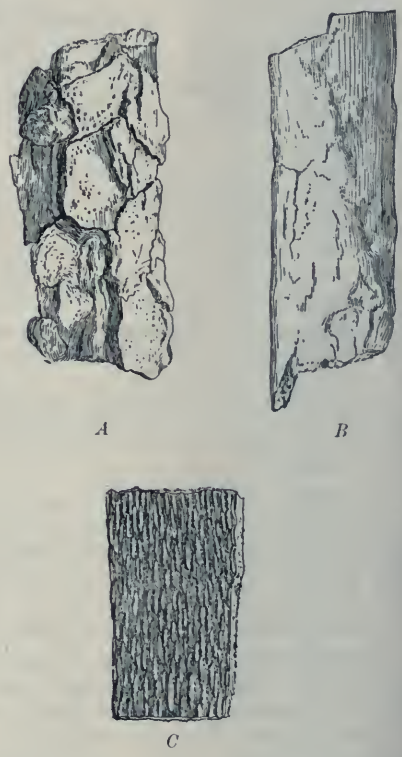
The stem-bark, which is frequently substituted, is in quills or quilled strips, reaches a greater thickness, is externally dark gray or blackish, deeply fissured and very scaly (or if very young smoothish, with some warts and oblong white spots), reddish brown if the corky layer has been removed; internally very finely short striate and harsh to the touch; fracture as in the root-bark, but the inner purple layer relatively thinner and distinctly white-radiate; taste more bitter.

The powder is of a reddish-brown color, and exhibits pitted stone-cells of very variable form, rarely exceeding 50 mikrons in breadth, bast-fibers mostly about half as thick and abundant calcium oxalate crystals, some single and large, others smaller and forming rosettes.

FIG. 145.

Dogwood: twig and inflorescence (½ Nat.).

FIG. 146.



Cornus: *A*, stem-bark; *B*, root-bark; *C*, inner surface of root-bark (*A* and *B*, Nat.; *C*, × 4).

Constituents.—The bark contains a bitter principle, *cornin* or *cornic acid*, crystallizing in silky needles, and soluble in water, alcohol, and ether. The other constituents are a tasteless resinous body, soluble in ether and hot alcohol, and insoluble in water; a bland, odorless, orange-colored fixed oil; gallic acid; and 3 per cent. of tannin. The "cornin" of the eclectics is a resinous extract.

Pharmaceutical Preparation.—FLUIDEXTRACT OF CORNUS, N. F.

Action and Uses.—Dogwood is a mild astringent, aromatic bitter, and stomachic. Formerly it was considered an antiperiodic, and was given in doses of from ½ to 1 ounce (16–30 Gm.) of the powdered drug between the paroxysms, in the treatment of mild malarial affections; but this use of it is now practically abandoned. As a simple bitter, it may be given in doses of from 15 minims to 1 fluidrachm (1–4 Cc.) of the fluidextract at meal-time. The other species of dogwood are bitter, astringent, and in large doses emetic.

Other Species.—The genus contains some 25 species of the north-temperate zone, a few extending into tropical mountains. All have a similar taste to the above, and probably share in its properties, and the following have been more or less extensively used like it:

C. CIRCINATA L. Herit, the *Round-leaved dogwood* or *Cornel*, of the same region as the official, is a slender shrub, forming copses. Its flowers lack the involucre of *C. florida* and the

fruit is light blue. The bark occurs in small, short quills or irregular small pieces, is only about 1 or 2 Mm. ($\frac{1}{25}$ or $\frac{1}{12}$ In.) thick, externally greenish, and with scattered light brown warts when young, brownish gray with the lighter-colored warts confluent in irregular lines or ridges when older. The inner surface is cinnamon brown and very finely striate. The fracture is short and even, the inner layer pale-reddish. Fluid extract of Cornus Circinata is official in the N. F.

C. Amomum Mill. (*C. sericea* L.), the *Swamp* or *Silky cornel*, *Red osier*, or *Kinnikinnick*, has a somewhat more extensive range than either of the others, and grows similarly in low places, especially along streams and on the borders of swamps. It is rather smaller than the last, and its stems are bright-red and the fruits bluish-white. The bark occurs in pieces much like those of the last, but are of a red-purple color and either quite smooth or less warty than that.

The bark of *C. stolonifera* Mx. is known by the same common names as the *C. Amomum*, closely resembles it, and is similarly used.

C. mascula L., of Europe, the *Cornelian cherry*, *Kornelkirsche*, *Dürlitze*, *Herlitze*, or *Corniola* (It.), and the *C. Canadensis* L., of North America, the *Low* or *Dwarf cornel*, *Bunchberry*, *Bunch-plum*, or *Crackerberry*, only a few inches high, but with inflorescences much resembling those of *C. florida*, yield fruits which are eaten to some extent.

Cornaceæ (*the Cornel or Dogwood Family*).—This small family (genera 15, species about 100) of shrubs and trees, growing in temperate regions, including high tropical mountains, is characterized by the possession of bitter constituents, properties, and uses, similar to those of cornus, on account of which several of them have become recognized as meritorious drugs. *Garrya*, the leaves and to some extent the bark, of *G. Fremontii* Torr., the *California fever-bush*, or *Skunk-bush*, an opposite-leaved evergreen shrub or small tree, with quadrangular branches, of the Pacific coast and Rocky Mountain region, is there extensively and successfully employed as a bitter tonic and mild antiperiodic. These leaves are shortly petioled, 2.5 to 8 Cm. (1 to 3 In.) long, and about as broad, oblong to ovate, narrowed at each end, and commonly mucronate, entire. They have a slight odor and are very bitter. The bitter constituent is said to be an alkaloid, *garryine*. The fluid extract is administered in doses of from 15 to 30 minims (1 to 2 Cc.). The bark, root, and leaves of *Alangium Lamarckii* Thw. (*Dhera*, *Akola*, or *Ankul*, *Alangi*, etc.), a small tree of India, contains the alkaloid *alangine*. This drug is a powerful bitter tonic, and is somewhat antiperiodic; emetico-cathartic in large doses, as is also the bark of *A. acuminatum* W. et A.

The wood of the root of several species of *Nyssa* L., of the southern United States, especially *N. aquatica* L. (*N. uniflora* Wang.), the large or *Swamp tupelo*, *Cotton*, *Black*, or *Sour gum*, of the Gulf States, has been considerably used as a substitute for sponges or laminaria in the making of uterine tents.

COTO.—Coto Bark.

The bark of an unknown tree (Fam. *Lauraceæ*) of northern Bolivia.

Origin.—The tree is a good-sized one, apparently of very local distribution along the lower portion of the La Paz River. A specimen seen by the writer in 1886 consisted of a lance-oblong leaf, nearly a foot long, and a large acorn-like fruit, similar to those of Nectandra and related genera.

Description.—In curved pieces of indefinite length (longitudinal sections of quills), and mostly 4 to 6 Cm. (about $1\frac{1}{2}$ to $2\frac{1}{2}$ In.) broad, the bark 0.5 to 1.5 Cm. (about $\frac{1}{4}$ to $\frac{1}{2}$ In.) thick, hard and heavy, of a deep-brown on both surfaces; outer surface smoothish, with a few very slight transverse fissures, occasionally transverse ridges, and a slight, thin scaliness, apparently having suffered the removal of most of the corky layer; inner surface very coarsely striate, but compact; fracture rather weak in view of the thickness, the outer half earthy, with an inner irregular and interrupted dark-red resinous band, the inner half coarsely long-splintery, of dark resin-tissue mixed with light-brown or yellowish bast-fibers and stone-cells; odor strongly and peculiarly aromatic; taste aromatic, at first merely pungent, then quickly peppery-biting.

In the powder, the large lemon-yellow stone-cells and thickened medullary-ray cells are characteristic; also the coarsely granular oil-globules in the parenchyma-cells (Schneider).

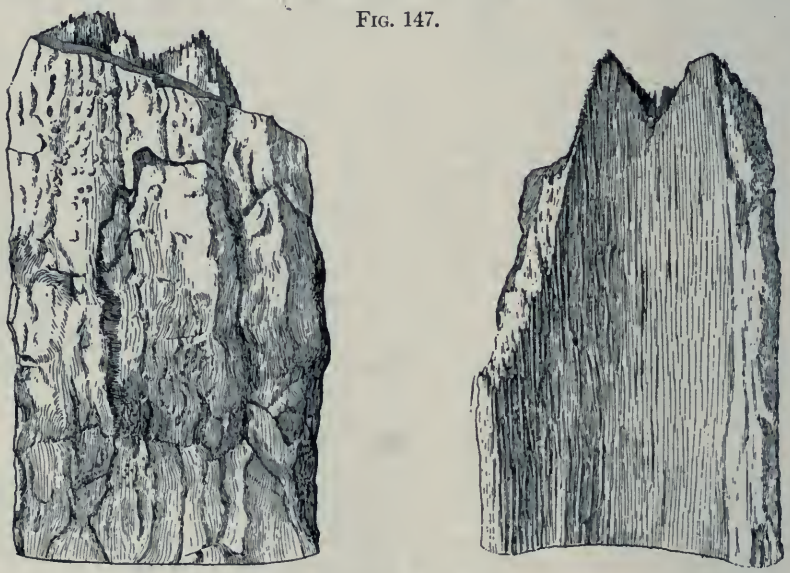
Constituents.—*Coto bark* yields a pale-yellow, aromatic, volatile oil of peppery taste, a volatile alkaloid, probably *propylamine*, *cotoin*, *phenyl-coumalin*, resin, starch, and *piperonylic acid* ($C_8H_6O_4$). *Cotoin* ($C_{14}H_{12}O_4$) crystallizes in light yellowish-white acrid and sternutatory prisms and plates, nearly insoluble in cold water, and soluble in boiling water, alcohol, ether, and chloroform. "Dicotoin" is a mixture (Hesse).

Substitutes.—The original and genuine coto bark has been greatly discredited by a number of inferior substitutes. It is now almost unobtainable, being replaced by Para-coto bark, itself of great and similar value, though distinctly inferior to coto.

Para-coto bark, its origin unknown, but evidently closely related to coto, also comes from Bolivia, but is more widely distributed and abundant than coto. Its appearance is closely similar, though it is usually thicker, and is covered, at least partly, by a silvery-gray soft periderm. Schneider finds the only histological distinction from coto to be the absence of the coarse oil-globules referred to above. Its taste offers the best mark of distinction, in that, while pungent, it lacks the secondary peppery-biting taste of coto, and has a distinct flavor which has been compared with that of nutmeg. It contains (Ciamician, Silber and Hesse, 1895) piperonylic acid, hydrocotoin ($C_{15}H_{14}O_4$), paracotoin ($C_{12}H_8O_4$), protocotoin ($C_{16}H_{14}O_6$), methyl-hydrocotoin ($C_{16}H_{16}O_4$), and methyl-protocotoin ($C_{17}H_{16}O_6$). Former analyses gave paracotoin ($C_{19}H_{12}O_6$), leucotin ($C_{34}H_{32}O_{10}$), oxyleucotin ($C_{34}H_{32}O_{12}$), hydrocotoin ($C_{15}H_{14}O_4$), and dibenzoyl-hydrocotoin ($C_{32}H_{32}O_8$).

Cotoin may be obtained by extracting coto bark with ether, recovering the bulk of solvent by distillation, and precipitating the resinous matter present in the residue by addition of ligroin or benzin. The clear liquid is decanted and allowed to evaporate spontaneously. The crude cotoin thus obtained may be crystallized from its solution in hot water or from alcohol or chloroform. It occurs in the form of pale-yellow needle-shaped crystals, which melt at 130° C. (266° F.) and are sparingly soluble in cold water, but readily soluble in alcohol, ether, chloroform, benzene, carbon disulphide, and acetone.

FIG. 147.



Para-coto bark (Nat.).

It is insoluble in benzin. Cotoin reduces silver nitrate solutions in the cold and Fehling's Solution when heated. If strong nitric acid be added to a solution of cotoin in glacial acetic acid, a blood-red color is produced.

Paracotoin may be extracted in a similar manner, and occurs in the form of pale-yellow glistening laminæ, which melt at 155° C. (311° F.). It resembles cotoin in behavior to different solvents, but is insoluble in benzene. Commercial paracotoin is usually contaminated with oxyleucotin, to which is due the yellow color changing to green when strong nitric acid is added to a solution of paracotoin in glacial acetic acid.

Pharmaceutical Preparations.—FLUIDEXTRACT OF COTO, N. F.; TINCTURE OF COTO, N. F.

Action and Uses.—In moderate amounts, coto bark acts as a tonic and stomachic. Overdoses produce gastro-intestinal irritation with severe pain and vomiting. The powder when locally applied is said to act as a mild counterirritant.

It is stated by those who have used it most, that coto may be successfully employed in the treatment of diarrhœa, particularly that following enteric fever, or that accompanying tubercular ulceration of the intestine. It has been reported to be efficacious in the treatment of cholera infantum, and has been proposed as a remedy for Asiatic cholera. Its chief, if not its sole, medicinal virtue consists in its checking diarrhœa of the atonic sort and without regard to its origin, but it is probable that it is harmful in

acute inflammatory conditions. Cotoin has been employed in the above conditions in the dose of ¾ grain (0.04 Gm.) subcutaneously.

Coto bark is not conveniently given in powder on account of its persistently acrid taste, but the proper dose is stated to be from 3 to 5 grains (0.20–0.30 Gm.), given 3 or 4 times a day. Cotoin has been given in doses of from 1 to 3 grains (0.05–0.20 Gm.), 3 times a day.

The tincture, made with 1 part of the bark and 8 parts of alcohol, and given in the dose of 2 fluidrachms (8 Cc.), sufficiently diluted, has been found the most convenient preparation. The fluidextract may be given in the dose of from 5 to 20 minims (0.3–1.3 Cc.).

Para-coto bark may be employed for the same purposes as coto bark. It is stated that paracotoin has been successfully used in the treatment of Asiatic cholera when administered subcutaneously in doses of 3 grains (0.20 Gm.).

Schuchardt has announced a coto bark from a species of *Drimys*, but its only relation to coto is in its name. It is bitter and mucilaginous, as well as aromatic, and evidently to be classed with the magnolia group.

CRASSULACEÆ.—The Cress Family.

Genera 13, species more than 400, fleshy and succulent plants of wide distribution, growing especially upon and among rocks. A few have been used as salads and potherbs. Because of their striking appearance, growing commonly with a dense rosette of thick, fleshy, radical leaves, they are naturally objects of conjecture and superstition. The belief is very common among the European peasantry that the growth of certain of them upon the roof-top protects against lightning-stroke, and marvellous stories of such protection are extant. Their mucilaginous properties adapt them for use as poultices, and many are so employed. These plants usually contain large amounts of malic acid. Many are active physiological agents, representing quite a wide range of activity. The commonest property and use are diuretic, the action being apparently wholly or chiefly local.

Sedum, or *Stonecarp*, is the herb *Sedum acre* L., of northern Asia and Europe, sparingly naturalized in the United States. It is designated as *Mossy* or *Biting stonecrop*, *Wall-* or *Poor-man's pepper*, *Pepper-crop*, *Wall-moss*, E.; *Mauerpfeffer*, *Steinkraut*, *Katzentraublein*, G.; *Poivre des murailles*, *Joubarbe acre*, Fr.; *Siempriviva menor*, Sp.; medicinally, as *Herba Sedi minoris* or *Herba illecebræ vermicularis*. It grows in patches, spreading by offsets, the erect stems being extremely short, and bearing spirally crowded leaves 3 to 6 Mm. (⅛ to ¼ In.) long, ovate, fleshy-thickened and convex on the lower surface, very smooth, punctate. The inflorescence is upon a short scape, branched above, the flowers nearly sessile on the upper sides of the somewhat recurved branches, the sepals, yellow petals and pistils each 5, the stamens 10. The drug is inodorous, mucilaginous, and acrid. It is said to contain rutin (see RUTA) and an amorphous non-volatile alkaloid, soluble in alcohol but not in water, as are its salts, to which the disagreeable and acrid taste is due. The biting taste is probably referable in part to a small amount of resin. This drug, applied externally, acts as a rubefacient and may even cause blistering. Internally, it is administered as a very active local and diffusive stimulant, diuretic, antiscorbutic, and generally as an alterative, and is in overdose a strong emetico-cathartic. It has distinct aphrodisiac properties. It is claimed to have been used with success for solution of the diphtheritic membrane, though no proteolytic enzyme has been reported. Similar properties appear to pertain to *S. Telephium* L. (*S. vulgare* Link, *S. purpureum* Haw.), the *Garden orpine*, *Live-for-ever*, *Bagleaf*, *Frog's bladder*, *Witch's Moneybags*, *Fetthenne*, *Grassette*, *Joubarbe des vignes;* medicinally employed under the names *Herba telephii*, *fabariæ*, or *crassulæ majoris*. It is native of the same regions as the last, and is naturalized as a troublesome weed in some parts of the United States. Belonging to the same medicinal group are *S. album* L., *S. sexangulare* L., and *S. boloniense* Lois., and doubtless very many other of the 150 species of this interesting genus; also *Sempervivum tectorum* L., the *European house-leek*, *Bullock's eye*, *Fone*, *Hen-and-chickens*, *Thunder-plant* (*Donnerkraut*), *Hauslauch*, *Dachlauch*, *Grande joubarbe*, *Siempreviva major;* medicinally known as *Herba siempreviva* or *sedi majoris;* *S. arboreum* L. and *S. montanum* L., the last named being a strong purgative. *Crassula portulacea* Lam., of the Cape of Good Hope, is, on the other hand, employed as an antidiarrhœal remedy. *Kalanchœ laciniata* DC. is applied to the temples for headache, in India, and is also a much-used vulnerary under the names *Parna-vija*, *Hemsager*, *Ghaipat*, and *Malakulti*. A number of the (nearly 100) species of *Cotyledon* L. are employed like *Kalanchœ* as vulneraries, *C. serrata* L. being in commerce in China under the name *Tau-shang-yoh*. *Bryophyllum calycinum* Salisb. (*Kalanchœ p.* Pers.; *Cotyledon pinnata* Lam.; *C. rhizophylla* Roxb.), widely distributed through tropical countries and marketed in India under the names *Airwan* or *Mairwan* and *Ghaimari*, is largely employed as a diuretic, as is also *Cotyledon lusitanicus* Lam. (*Umbilicus erectus* DC.).

Penthorum, the *Virginia* or *Ditch stonecrop*, is a very common herb of ditches and other moist localities throughout eastern North America, and is an important drug among the eclectics. Description: Smooth; stem about 3 Dm. (1 Ft.) long, usually simple except above; leaves very short-petiolate, scattered, 5 to 7 Cm. (2 to 3 In.) long and one-third as

wide or less, lanceolate, acuminate and acute, sharply serrate, smooth and thin; flowers small, greenish, along the upper sides of several slender branches of the terminal cyme, short-pedicelled, 5-merous like the sedum above described. It is almost odorless and has only a slightly astringent taste. No constituent other than tannin has been isolated from it. Its use is purely empirical, chiefly in catarrhal conditions, and its value is highly problematical.

CREOSOTUM, *U. S.*, *Br.*—Creosote.

Kreosotum, P. G.—*Créosote*, Fr.; *Kreosot*, *Buchenholztheerkreosot*, G.; *Creosoto*, It.

A mixture of phenols and phenol derivatives, chiefly guaiacol and creosol, obtained during the distillation of wood-tar, preferably of that derived from the beech, *Fagus sylvatica* L. or *Fagus ferruginea* Ait.—U. S.

A mixture of guaiacol, creosol, and other phenols, obtained in the distillation of wood-tar.—Br.

Preparation.—Wood-tar is distilled until about one-half is passed over and dense vapors of paraffin, etc., make their appearance. The distillate separates into a heavy and a light oily layer, with an intervening aqueous stratum of an acid reaction. The light oil contains *eupion*. The heavy oil is treated with a concentrated solution of sodium carbonate, and the separated oily liquid is distilled, that portion of the distillate only being collected which is heavier than water. This distillate is treated with potassium hydroxide solution, specific gravity 1.12, whereby the creosote is dissolved and *eupion* separated. The potassium hydroxide solution is now supersaturated with sulphuric acid, and the precipitated creosote well washed with water and rectified, the product distilling at 200°–220° C. (392°–428° F.) being collected. The treatment with potassium hydroxide and sulphuric acid is repeated until the potassium creosote solution does not turn brown on being heated in the air.

To obtain creosote from crude pyroligneous acid, the oily constituents are first separated by saturating the crude acid with sodium sulphate at about 70° C. (158° F.), and while warm skimming off the supernatant layer. The cold thick oil is distilled, treated with sodium carbonate, and further purified as above.

Creosote is a mixture of phenoloid compounds, principally of the series of acid methylic ethers of catechol and its homologues, and varies in composition according to the method of its preparation and the wood from which it is prepared. According to Voelckel, it is the product of the incrusting layers of the cells rather than of the cellulose. It was prepared first by Reichenbach (1830), and in 1867 Gorup-Besanez recognized the principal constituents of beechwood-tar creosote as *guaiacol*, $C_7H_8O_2$ or $C_6H_4.OCH_3OH$, and *creosol*, $C_8H_{10}O_2$ or $C_6H_3.CH_3.OCH_3.OH$; both are oily liquids having the general properties of creosote, the former boiling at 200° C. (392° F.), the latter at 219° C. (426.2° F.). Heated with hydriodic acid, both yield methyl iodide, and in addition thereto *pyrocatechin*, $C_6H_4(OH)_2$, is produced by the former, and by the latter a non-crystallizing body isomeric with orchin, $C_7H_8O_2$. Tiemann and Mendelssohn (1876) proved also the presence of *xylenol* or *phlorol*, $C_6H_{10}O$, which previously had been supposed to exist in it and in impure carbolic acid. They dissolved the portion obtained by fractional distillation near 220° C. (428° F.) in ether, and added concentrated potassium hydroxide solution, whereby its compound with creosol was separated, while the phlorol remained in the mother-liquor. Reimer observed (1876) that guaiacol, treated with chloroform and sodium hydroxide, and afterward with an acid, is converted into *vanillin*, the aldehyde of *vanillic acid*, which latter was obtained from creosol by converting it first into acetyl-creosol and oxidizing this with potassium permanganate (Tiemann and Mendelssohn, 1877). Besides the three principles named, others are likely to be present in creosote from different sources, such as *methyl-creosol*, $C_9H_{12}O_2$ (boiling-point 215° C. = 419° F.), and *methyl-guaiacol*, $C_8H_{10}O_2$ (boiling-point 205° C. = 401° F.). The cresols and phenols boiling below 200° C. (392° F.) should be absent.

Attention must be called to the fact that the pharmacopœial creosote is the product of the dry distillation of *wood*, and that it should not be confounded with the substance occasionally offered as "coal-tar creosote," prepared from coal, as the latter is of a different composition and poisonous, and should never be used in medicine or pharmacy. Beechwood creosote is richer in guaiacol than that obtained from the wood of the oak. Behal and Choay (*Rep. de Pharm.*) found the distillates obtained at 200°–210° C. (392°–410° F.) from beechwood creosote and that from oak to contain respectively 39 and 55 per cent. of monovalent phenols, 26.4 and 14 per cent. of guaiacol, and 32 and 31 per cent. of creosol and its homologues.

Properties.—Creosote is a colorless to yellowish (not pinkish), highly refractive, oily liquid having a penetrating, smoky, aromatic odor, a pungent, burning taste, and a neutral, only faintly acid, reaction to litmus-paper. Its specific gravity should not be below 1.072 at 25° C. (77° F.), U. S.; at 15° C. (59° F.), 1.080, P. G.; 1.079, Br. It is soluble in about 140 parts of water at 25° C. (77° F.), but without forming a perfectly clear solution. With 120 parts of hot water it forms a clear liquid, which becomes turbid on cooling and separates oily droplets. The filtrate from these oily globules yields a reddish-brown precipitate with bromine test-solution (distinction from phenol and so-called coal-tar creosote, both of which yield white precipitates). It is soluble in all proportions in absolute alcohol, ether, chloroform, benzin, carbon disulphide, acetic acid, fixed and volatile oils. It dissolves a considerable proportion of iodine, phosphorus, and sulphur. It begins to boil at about 200° C. (392° F.), and most of it distils over between 200° and 220° C. (392°–428° F.), U. S., P. G., Br. When cooled to —20° C. (—4° F.), it becomes gelatinous, but does not solidify (difference from phenol), It is inflammable, burning with a luminous, smoky flame. It takes up 50 per cent. of glycerin or 15 per cent. of ammonia, specific gravity 6.940. When agitated with an equal bulk of ammonia water it separates unchanged on standing, but it dissolves in potassium or sodium hydroxide solution, the liquid becoming discolored when exposed to air, and giving off creosote when heated to boiling. Heated with ammonia-water to 60° C. (140° F.), then spread over a porcelain surface and subjected to the action of bromine vapors, a brown to green color is developed (phenol produces a blue color). It causes precipitates with solutions of gum and albumen, but not with gelatin, and does not render collodion gelatinous (difference from phenol). It is an antiseptic and preservative; it is owing to the presence of creosote in the smoke of burning wood that smoked meats have their keeping qualities prolonged. Creosote reacts violently with strong nitric acid. Sulphuric acid dissolves creosote with a red color, gradually changing to purple violet. With concentrated hydrochloric acid it produces a deep-red color which in contact with air changes to brown or black.

Tests.—1 Gm. should dissolve clear in 120 parts of hot water, and the solution turn turbid or milky on cooling to 15° C. (59° F.) (excess of phenols would increase the solubility). The specific gravity should not be below 1.075. One or two drops placed upon blue litmus-paper should not redden it even after moistening it with water. On mixing equal volumes of creosote and collodion in a dry test-tube, no permanent coagulum should form. If 1 volume of creosote be mixed with 1 volume of glycerin, a nearly clear mixture will result, from which the creosote will be separated by the addition of one-fourth volume of water. On adding to 10 Cc. of a saturated aqueous solution of creosote 1 drop of ferric chloride test-solution, the liqutd will acquire a violet-blue tint which rapidly changes to greenish and brown, with formation, usually, of a brown precipitate. (The three preceding tests show difference from phenol and so-called coal-tar creosote, and limit of the former.) On mixing 2 Cc. of creosote with 10 Cc. of normal solution of sodium hydroxide, a clear, pale-yellowish liquid results, which becomes turbid when diluted with water, but clears up after 50 Cc. have been added (absence of neutral oils). If 1 Cc. of creosote be mixed with a 20 per cent. solution of potassium hydroxide in absolute alcohol, a solid crystalline mass will form upon cooling. If 1 Cc. of creosote is shaken with 2 Cc. of petroleum benzin and 2 Cc. of freshly prepared barium hydroxide test-solution, upon separating, the benzin should not be blue or muddy, and the aqueous layer should not have a red tint (absence of cœrulignol and some other high-boiling constituents of wood-tar).—U. S. If creosote be shaken with 5 times its bulk of ammonia water (10 per cent.), its volume should not be diminished materially (distinction from phenol).—Br.

Excess of water may be determined by heating 10 Cc. of the creosote with 2 Gm. of crystallized calcium chloride until the salt melts, mixing the liquids and cooling thereafter. In presence of water the calcium chloride does not again solidify.

Frŏhde's reagent, prepared by dissolving 1 part of molybdic acid in 1000 parts of sulphuric acid, has been found by E. W. Davy (1878) to be a reliable test for detecting an admixture of carbolic acid in creosote, the former producing with the reagent a yellowish or brownish tint, passing into maroon or reddish-brown, and finally into beautiful purple; the latter causes a brown or reddish-brown color, which becomes fainter, and finally light yellowish-brown. The test is applied by adding 1 or 2 drops of the aqueous solution of the substance to 3 or 4 drops of the reagent; warming the mixture gently will hasten the production of the final coloration. If the creosote contains but a small

quantity of carbolic acid, 10 drops of it are dissolved in ½ ounce of water and the solution distilled. The first portion of the distillate will give the creosote reaction, and the last portion that of carbolic acid.

The amount of guaiacol may be approximately determined as follows: 5 Cc. of the creosote are mixed with 50 Cc. of alcoholic potash (1 part of potassium hydroxide in 5 parts of absolute alcohol). The mixture solidifies in from 10 to 30 or 40 minutes according to the amount of guaiacol present. The crystalline mass is pressed between filter-paper, decomposed by warming with 5 Cc. of 10 per cent. sulphuric acid, water added until the mixture of creosol and guaiacol sinks, the aqueous solution poured off, and 4 Cc. of ammonia added. Guaiacol gives a hard crystalline mass, while creosol gives only semifluid scales after some time which are soluble in petroleum spirit, while the guaiacol compound is insoluble (Merklen).

Pharmaceutical Preparation.—Creosote Water, U. S. P.

Action and Uses.—Creosote is employed in medicine for several purposes. The most important of these is as a remedy in pulmonary tuberculosis. In this disease it has been thought to act as a curative agent, but as a matter of fact its influence over the tubercular process is very limited, and it does good chiefly by acting as a stimulating expectorant and by relieving the associated bronchitis. Usually, large doses are required to control the cough, and these are apt to irritate the stomach. Creosote has been given by the rectum in cases of tubercular peritonitis, but this practice is rarely resorted to.

As creosote acts as an antiseptic, it has been used as a remedy in fermentative dyspepsia and diarrhœa, with good results in some cases. Owing to its anæsthetic properties, it may be used in obstinate vomiting due to irritability of the stomach.

The dose varies from 1 to 20 minims (0.05–1.30 Cc.), according to the needs of the case; it may be given in capsule, in wine, in milk, and in other vehicles.

When poisonous doses of creosote are taken, the patient suffers from all the symptoms of carbolic acid poisoning (see Carbolic Acid), and the treatment is identical with that instituted for poisoning by that drug, the chief antidote being any soluble sulphate, such as sulphate of magnesium. (See also Guaiacol.)

COMPOUNDS OF CREOSOTE.

Creosoti Carbonas. *Creosote carbonate, Creosotal,* E.; *Kreosotkarbonat,* G.—Creosote carbonate is prepared by conducting a current of carbon oxychloride into a solution of creosote in sodium hydroxide solution. The oil which separates is washed with a dilute aqueous solution of sodium hydroxide and finally with water. It is a thick, yellowish, oily liquid, quite odorless and tasteless, insoluble in water, soluble in ethyl, methyl, and amyl alcohol, chloroform, and benzene. Boiled with potassium hydroxide solution the odor of creosote is evolved. Creosote carbonate contains the equivalent of 90 parts of beechwood creosote. This is a useful substitute for creosote, being less irritating. Some practitioners assert that it is most valuable in croupous pneumonia. Its dose is from 5 to 10 grains (0.30–0.60 Gm.).

Creosoti Oleas. *Creosote oleate,* E.; *Oelsaures Kreosot, Oleokreosot,* G.—A light-yellowish oily liquid, quite odorless, insoluble in water, difficultly soluble in 90 per cent. alcohol, readily soluble in absolute alcohol, ether, chloroform, benzene, and fixed and volatile oils.

Creosoti Phosphas. *Creosote phosphate. Phosote.*—This is prepared by allowing creosote and phosphoric anhydride to act upon each other in presence of sodium. A thick, syrupy mass results, which is washed with water and subjected to fractional distillation, and the fraction distilling between 190° and 203° C. (374°–397.4° F.) collected separately, dissolved in alcohol, and precipitated by addition of water. Creosote phosphate is a thick, oily liquid having an astringent, bitter taste. It is insoluble in water, glycerin, and fixed oils, but soluble in alcohol or ether. It contains 25 per cent. of phosphoric acid and 75 per cent. of creosote, into which constituents the ester is easily decomposed by treatment with solutions of alkali hydroxides.

Creosoti Tannas. *Creosal. Tannosal.*—Creosal is a tannic acid ester of creosote. It is a brown amorphous hygroscopic powder, having the odor of creosote, and is readily soluble in water, alcohol, and glycerin. It contains 60 per cent. of creosote and 40 per cent. of tannic acid.

Creosoti Valerianas. *Creosote valerianate. Eosot. Baldriansaures Kreosot,* G.—15 parts of creosote, 20 parts of valerianic acid, and 7 parts of phosphorus oxychloride are heated together until hydrochloric acid ceases to distil. The resulting ester is washed with 3 per cent. sodium hydroxide solution, dissolved in benzene, and recovered on evaporation of the latter. Creosote valerianate is a light-yellowish oily liquid, having an odor suggestive of creosote and valerianic acid, boiling at about 240° C. (464° F.), and is insoluble in water, but soluble in alcohol, ether, and fixed and volatile oils.

Phosphotal. *Phosphatal.*—Trade name for the esters of creosote with phosphorous acid.

CRESOL, *U. S.*—Cresol.

Cresolum, Cresolum purum.—Cresylic acid, Methylphenol, Tricresol, Oxytoluene, E.; *Cresol,* Fr.; *Kresol, Trikresol, Enterol,* G.

Formula, C_7H_7OH or $C_6H_4(CH_3)OH$. Molecular weight, 107.25.

A mixture of the three isomeric cresols obtained from coal-tar, freed from phenol, hydrocarbon, oils, and water. It should be preserved in amber-colored bottles protected from light.—U. S.

Preparation.—Cresol is prepared commercially from the "phenol" distillates of coal-tar obtained between 140° and 220° C. (284°–428° F.). The phenols are dissolved in sodium hydroxide solution, and by careful dilution with water and the addition of a limited amount of hydrochloric or sulphuric acid most of the hydrocarbons (benzene, naphthalene, toluene, etc.) and tarry matter are separated. To the clarified filtrate a further limited amount of hydrochloric acid (insufficient to liberate the carbolic acid) is added, and the precipitated cresols separated from the carbolic acid, which remains in solution. The product is "crude carbolic acid," although not identical with the article sold under that name in this country, and for further purification is redissolved in sodium hydroxide solution, subjected to fractional precipitation with hydrochloric acid as above, and the precipitated acids finally fractionated by distillation between 180° and 200° C. (356°–392° F.), the product constituting crude *cresol* (*Cresolum crudum—Rohes Kresol,* P. G.). By further purification and subsequent distillation between 190° and 205° C. (383° and 401° F.) the official article may be obtained.

Properties and Tests.—Official cresol occurs as a colorless or straw-colored refractive liquid, having a phenol-like odor and turning yellowish brown on prolonged exposure to light. Its specific gravity is 1.032 at 25° C. (77° F.). It is soluble in 60 parts of water at 25° C. (77° F.); miscible in all proportions with petroleum benzin, benzene, alcohol, ether, and glycerin. Also miscible with alkali hydroxide solutions. Cresol boils at from 195° to 205° C. (383°–401° F.). If 1 Cc. of cresol be mixed with 1 Cc. of an aqueous solution of sodium hydroxide (1 in 10), it should dissolve with no appreciable liquid residue (absence of or limit of hydrocarbon oils). If 1 Cc. of cresol be mixed with 1 Cc. of glycerin, a clear solution should be produced, from which, on the addition of 1 Cc. of water, the cresol should completely separate (absence of and distinction from phenol).—U. S

Cresol is composed principally of the 3 isomers *ortho-*, *meta-*, and *paracresol*, represented by the formula C_7H_8O or $C_6H_4CH_3OH$, and to which the names cresylic acids, cresylic hydrates, methyl-hydroxybenzene have also been applied. *Metacresol* is a liquid which boils at 201° C. (393.8° F.), but does not solidify even at —80° C. (—112° F.), and is convertible into meta-hydroxybenzoic acid by fusion with potassium hydroxide. *Orthocresol* and *paracresol* form colorless prisms with phenol-like odor, and dissolve sparingly in water; both give a blue color with ferric chloride. Orthocresol melts at 31° C. (87.8° F.), boils at 185° C. (365° F.), and by prolonged heating with potassa is converted into salicylic acid. Paracresol melts at 36° C. (96.8° F.), boils at 198° C. (388.4° F.), and by heating with potassa is converted into paraoxybenzoic acid. The 3 cresols are variously affected by the oxidizing ferment of mushrooms, orthocresol being oxidized with the formation of a greenish-brown liquid and a dull-green precipitate, soluble in ether; paracresol forming a red liquid which afterward turns green, the coloring-matter being insoluble in ether; metacresol yields a rose-white precipitate soluble in alcohol (Bourquelot).

The crude cresol of the P. G. is a clear liquid of yellowish to yellowish-brown color, and having an empyreumatic odor. It has a neutral reaction, is heavier than water, and is imperfectly soluble in water, but soluble in alcohol and ether. 10 Cc. of crude cresol shaken in a 200 Cc. cylinder with 50 Cc. of sodium hydroxide test-solution and 50 Cc. of water, should not separate more than a few flakes after standing some time; after adding 30 Cc. of hydrochloric acid and 10 Gm. of sodium chloride and thoroughly shaking the mixture, an oily layer measuring 8.5 to 9 Cc. should separate, 0.5 Cc. of the separated cresols shaken with 300 Cc. of water and 0.5 Cc. of ferric chloride solution should produce a blue-violet coloration.

The cresols possess strong disinfectant, antiseptic, and germicidal properties, the metacresol being the most powerful, while at the same time they are far less poisonous than

carbolic acid. In combination with sodium as sodium cresylate, C_7H_7ONa, which renders the cresols soluble in water, or by sulphonation with sulphuric acid, various combinations have been commercially introduced, as solveol, solutol, sapocresol, lysol, saprol, creolin, etc.

Action and Uses.—Cresol is an antiseptic whose uses are similar to PHENOL (which see). It is an ingredient of several proprietary antiseptic preparations.

PREPARATIONS OF CRESOL.

Creolinum. *Creolin*, E.; *Creoline*, Fr.; *Kreolin*, G.—Creolins are disinfectant and antiseptic soluble preparations of cresols (quite free from carbolic acid), rendered soluble by means of soap or by sulphonation with sulphuric acid. The former class is represented commercially by Pearson's (British) and the latter by Artman's (German) creolin. The methods for their preparation are trade secrets. Creolins of the Pearson type are reddish-brown to reddish-black syrupy liquids having a tarry odor, vary in specific gravity from 1.040 to 1.078, and form clear solutions with alcohol, ether, chloroform, benzene, benzin, etc. Published analyses by Weyl, Fischer, Beckurts, and Otto indicate the presence in the British creolin of about 60 per cent. of hydrocarbons boiling between 190° and 350° C. (384°–662° F.), 10 to 22 per cent. of phenols boiling between 200° and 300° C. (392°–572° F.), about 0.8 per cent. of pyridine bases, etc.; while a more recent analysis by Pfrenger gives the composition of Pearson's creolin as: phenols, 12.67; hydrocarbons, 44.94; organic bases, 2.76; sodium, 1.45; rosin, 32.45, etc.; and analyses of certain German-creolins show the latter to contain from 17 to 21 per cent. of rosin soap and about 56 per cent. of "30 per cent." carbolic acid. In both preparations the phenols are combined with an alkali (sodium or potassium), and the hydrocarbons are held in solution by the compounds thus formed. *Disinfectol*, *Izal*, *Entcrokresol*, and *Sapokarbol* belong to the same class. Artman's creolin contains less phenols, but a much larger percentage (85 per cent.) of hydrocarbons, and differs from the above class in being but little soluble in ether, and in depositing when refrigerated for some time hard white crystals of naphthalene, which are sublimable and melt at 79°–80° C. (174.2°–176° F.), boiling at 216°–218° C. (420.8°–424.4° F.). The sulphonated cresols are capable of holding free cresols in solution and form milky emulsions with water. Recent researches have shown sodium salicylate to be a good solvent of cresols. When added to water in the proportion of 2 per cent. creolin is a useful antiseptic in the lying-in state, being employed as a wash for the hands, and in those cases which require vaginal irrigation. It does not make a good solution in which to place instruments prior to operation, as it forms an opaque mixture with water, and so prevents them from being seen at the bottom of the pan in which they are placed.

Cresalol. *Cresol salicylate. Cresol salol.* $C_6H_4(OH)COOC_6H_4CH_3$. or $C_6H_4CH_3.C_7H_5O_3$.—When a mixture of sodium salicylate and sodium cresylate in molecular proportions is heated with phosphorus oxychloride, cresol salicylate or cresalol is obtained. Three isomers of this compound are possible, depending upon the use of sodium ortho-, meta-, or paracresylate. It is a crystalline powder, soluble in alcohol and ether, but insoluble in water. In its action and uses it resembles salol, which see. Dose, 5 to 30 grains (0.3–2 Gm.).

Cresin.—A brown clear liquid, soluble in water and alcohol, and obtained by dissolving 25 parts of cresol in 75 parts of solution of sodium cresoxylacetate. Used as a disinfectant.

Cresol Iodide. *Iodocresol. Traumatol.* C_7H_7OI.—Prepared by the action of a solution of iodine in potassium iodide upon an emulsion of cresol in water. A reddish-violet odorless amorphous powder containing about 55 per cent. of iodine, soluble in alcohol, oils, and alkaline solutions, difficultly soluble in ether, insoluble in water.

Cresol Triiodide. *Metacresol triiodide. Losophane, Trijodmetakresol*, G. $C_6HI_3(CH_3)OH$.—Prepared by the action of a solution of iodine in potassium iodide upon the sodium salt of o-oxy-p-toluic acid. A colorless to slightly yellowish crystalline powder, melting at 121.5° C. (251° F.), insoluble in water, difficultly soluble in alcohol, readily soluble in ether, chloroform, benzene, hot oils, and in dilute aqueous solution of sodium hydroxide. Concentrated solutions of alkali hydroxide decompose it. It contains 78.39 per cent. of iodine.

Liquefied Orthocresol.—This preparation is recognized in the Austrian Pharmacopœia as *Cresolum liquefactum*. It is a colorless oily liquid having an odor suggestive of carbolic acid and cresol, and prepared by fusing 100 parts of orthocresol and incorporating therewith 10 parts of distilled water.

Liquor Cresoli Saponatus, P. G. *Solution of cresol soap*, E.; *Kresolseifenlösung*, G. *Liquor disinfectans.*—This is prepared by dissolving 1 part of crude cresol in 1 part of a potassium soap, with constant stirring and the application of heat until a homogeneous fluid is obtained. A yellowish-brown to brown oily, saponaceous liquid, having the odor of cresol, a specific gravity of 1.055, forming a clear solution with distilled water, and miscible with alcohol, chloroform, glycerin, and benzin. It is 3–5 times more powerful as a bactericide than carbolic acid, and much less poisonous. Similar preparations are marketed under the trade names *Sapocresol*, *Crelium*, *Phenolin*, *Lysol*, and *Kresapol*, and are all used as antiseptics.

Potassium Orthodinitrocresylate. *Antinonnin.* "*Saffransurrogat,*" G. $C_6H_2.(NO_2)_2.CH_3.OK$.—A yellow coloring-matter obtained by diazotizing a nitric acid solution of nitro-o-toluidin with sodium nitrite and converting the diazotoluene nitrate formed into *dinitrocresol* by gradually dropping it into boiling nitric acid. The dinitrocresol is neutralized with potassium carbonate. The dry salt is explosive, to overcome which the potassium dinitrocresylate (50 parts) is mixed with soap and glycerin, forming a reddish-brown paste. The latter dissolved in 300 to 1000 parts of water is a good insecticide spray for plants.

Solutol.—A brown transparent oily liquid of strong alkaline reaction, miscible with water, and containing about 60 per cent. of cresols, of which about one-fourth is free cresol and three-fourths in combination with sodium.

Solveol.—A brown transparent oily neutral solution of cresol in which the cresol is held in solution through the agency of the sodium salts of salicylic, cresylic, or benzoic acid. Soluble in alcohol, and miscible with water.

Tricresolamine. *Ethylenediamine-tricresol, Kresamin.*—A clear colorless aqueous solution containing 2 per cent. of tricresol and 2 per cent. of ethylenediamine.

CRETA PRÆPARATA, *U. S., Br.*—Prepared Chalk.

Creta lævigata.—Craie préparée, Craie lavée, Fr.; *Präparirte Kreide, Schlämmkreide,* G.; *Creta preparada,* Sp.

Formula, $CaCO_3$. Molecular weight, 99.35.

Native calcium carbonate, freed from most impurities by elutriation, existing either as a powder or moulded into conical drops.

Neither the U. S. nor the Br. Pharmacopœia now gives a process for the preparation.

Origin.—Chalk is a mineral found in many parts of the world, and very abundantly on the coasts of the English Channel. It consists mainly of the microscopic shells of *Foraminifera,* and, chemically, is calcium carbonate, generally containing a little silica, aluminum, iron, magnesium, and organic matter. It is usually soft and earthy, but occasionally compact and rather hard, often of a yellowish-white or even red color, due to ferric oxide; as met with in commerce it is nearly white. Its specific gravity is about 2.5. It is much used for making marks which are readily effaced. Freed from the hard, silicious portions by pulverization and diffusion in water, it constitutes *whiting,* and if prepared from very white and soft chalk it is known as *Spanish* or *Paris white* (*Blanc d'Espagne, Blanc de Paris,* Fr.). The latter, mixed with coloring-matters and moulded into pencils, forms the main ingredient in *pastil* colors. Being very rapidly and almost completely dissolved by hydrochloric acid, chalk is not adapted for generating a continuous stream of carbon dioxide. To be suitable for medicinal purposes it requires to be purified or *prepared.*

Preparation.—Prepared chalk is obtained by elutriation, which consists in suspending native chalk in cold water, allowing the coarser particles to subside, decanting the milky liquid on suitable straining cloths, and collecting the residue while still moist, and forming the same into small nodules by dropping the soft mass from a funnel-shaped vessel on to porous tiles or other suitable drying trays. The dry powder coheres loosely in the form of small cones. The heavy portion first separated may be triturated with water and again treated as above.

Properties and Tests.—Prepared chalk is in conical nodules, forming a white, amorphous, insipid powder, and, being nearly pure calcium carbonate, has all the physical properties of that compound (see page 336), except that the color is usually of a less bright tint, and that, viewed under the microscope, the particles do not present a crystalline appearance. The chemical behavior is likewise the same, except that on dissolving prepared chalk in diluted hydrochloric, nitric, or acetic acid a trifling insoluble residue is usually left, and that the rapid and copious effervescence of carbon dioxide gas produces a more permanent foam. When heated to redness, prepared chalk loses carbon dioxide and is converted into lime. The solution in diluted acetic acid yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic, but soluble in hydrochloric acid.

Substitutes.—*Powdered gypsum,* calcium sulphate, has been during the past 30 years repeatedly sold in place of prepared chalk. It is of a whiter color, does not effervesce with acids, and yields with a large quantity of distilled water a neutral solution giving white precipitates with barium chloride and ammonium oxalate, the latter being soluble in diluted hydrochloric acid.

Pharmaceutical Preparations.—Aromatic Chalk Powder, N. F.; Aromatic Chalk Powder with Opium, N. F.; Compound Chalk Powder, U. S. P.; Chalk Mixture, U. S. P.; Troches of Chalk, U. S. P.

Action and Uses.—Prepared chalk is a mild, non-irritating astringent and an excellent antacid. It may be employed internally in the treatment of gastric acidity and in the various forms of diarrhœa. It is especially adapted to the treatment of diarrhœa resulting from intestinal fermentation with the formation of acid stools. In this condition, however, it should be preceded by a purge. It is also to be remembered as an antidote to poisoning by oxalic acid. As a dusting-powder it may be applied with benefit in the treatment of superficial ulcers, burns, scalds, and abrasions. Prepared chalk is preferable to precipitated calcium carbonate, as it is more impalpable and more absorbent. It is stated that the products prepared from coral, fishbone, and crabs' eyes are more acceptable to the stomach. This may be due to the fact that small quantities of calcium phosphate are present. The internal dose is from 10 to 40 grains (0.60–2.6 Gm.), best administered with mucilage or syrup (see Mistura Cretæ).

Allied Drugs.—1. Corallium.—*Coral*, E., Sp.; *Corail*, Fr.; *Koralle*, G.—*Oculina virginea* Lamarck, and *Corallium rubrum* Lamarck (*s. Isis nobilis* Pallas). Class *Polypiphera*. Corals are polypipherous animals inhabiting the sea, and consisting of a skeleton and a fleshy portion. Those which were formerly, and are still occasionally, employed in medicine have a calcareous skeleton which branches considerably, assuming the form of a tree or shrub, on the branches of which the individual animals are located in tube-like apertures. Of the numerous species which have been distinguished, the skeletons of only two have been used. The first one mentioned above has a milk-white color, the second is of a dull-red. Besides a small quantity of organic matter, coral consists almost exclusively of calcium carbonate, with a little magnesium carbonate. The color of red coral is due to about 4.25 per cent. of ferric oxide.

2. Lapides (*s.* Oculi *s.* Calculi *s.* Lapilli) cancrorum.—*Crabs' eyes, Crabs' stones*, E.; *Yeux (Pierres) d'écrevisses*, Fr.; *Krebsaugen, Krebssteine*, G.; *Ojos de cangrejos*, Sp.—They are concretions contained in the stomach of the crawfish, *Astacus fluviatilis* Fabricius, class *Crustacea*, and are obtained in Russia by allowing the animals to putrefy and washing the mass with water. They contain about 63 per cent. of calcium carbonate and 17 per cent. of calcium phosphate, the remainder being various animal matters with small quantities of other salts. Factitious crabs' stones, which are sometimes met with, are completely dissolved or disintegrated by hydrochloric acid.

3. Os Sepiæ.—*Cuttlefish-bone*, E.; *Os de sèche*, Fr.; *Sepie, Weisses Fischbein*, G.; *Hulsas de Xibia*, Sp.—It comes chiefly from the Mediterranean, from *Sepia officinalis* L., class *Cephalopoda*, and is the calcareous bone contained in the mantle of the animal. It is of a white color, and consists of 80 to 85 per cent. of calcium carbonate, with traces of phosphates, 12 to 16 per cent. of animal matter, and about 4 per cent. of moisture.

4. Testa præparata, U. S. 1870; *Conchæ præparatæ*, P. G. 1872.—*Prepared oyster-shell*, E.; *Magistère de coquilles (d'écailles) d'hûitres*, Fr.; *Präparirte Austerschalen*, G.—From the shell of *Ostrea edulis* L., class *Acephala* (*Conchifera*), ord. *Lamellibranchia*, Fam. *Ostracea*. The principal constituent of oyster-shells is calcium carbonate, which varies in the different layers between 88 and 98 per cent., the pearly inner layer containing the largest quantity. The organic matter present in oyster-shells may vary between 0.5 and 4.5 per cent. The remaining inorganic constituents are small amounts of calcium phosphate and sulphate, magnesium, silica, oxide of iron, and alumina.

CROCUS, *Br., P. G.*—Saffron.

Stigmata Croci, Stigmata Croco, Spanish Saffron; Safran, Fr., G.; *Zafferano*, It.; *Azafran*, Sp.; *Acafrao*, Port.

The dried stigmas of *Crocus sativa* L. (*C. officinalis* Martyn.—Fam. *Iridaceæ*).

Crocus is official in all pharmacopœias. Several of them require that the test-coloration be produced within an hour. There is considerable variation among them as to the allowable loss in drying, which amounts to from 12 to 14 per cent., as well as in the amount of ash, from 7 to 8.5 per cent., the higher percentage from the "thoroughly dried drug." Some caution against the styles, while one expressly admits them, and there are various provisions against the common adulterants.

Origin.—A low bulbiferous plant with grass-like leaves and pale-purple flowers, a native of southwestern Asia and adjacent Europe, very extensively cultivated in Asia and throughout southern Europe, and considerably naturalized in the latter region. In India, the bulbs have been eaten in times of famine. It is more extensively used among the ignorant Orientals than in Europe and America, and those people produce their own

supplies. Our product comes chiefly from Spain and France. Crocus has been successfully grown in the United States, but the high cost of labor forbids profit. The stigmas of nearly 4000 flowers are required to yield 1 ounce of dry saffron, and it is estimated that about 33 to 36 pounds can be produced to the acre.

Attempts have been made to develop races of the plant possessing duplicated stigmas, or with stigmatic appendages to the stamens and petals. It appears doubtful whether the latter would possess the constituents of normal stigmas, though the former probably would.

FIG. 148.

Crocus sativus L.: *a*, stigma, upper part (× 4); *b*, style with stigmas; *c*, papillose margin of stigma (× 120).

Description.—Separate, or 3 attached to a very short portion of their style, each 2 to 3 Cm. (about 1 In.) long, flattish-filiform below, dilated and funnel-form tubular above, with the margin irregularly notched; orange-brown, the style-portion yellow; texture somewhat cartilaginous, unctuous to the touch, strongly and peculiarly aromatic and bitterish.

If genuine and pure saffron be thrown upon the surface of warm water, it will very quickly expand to display the characteristic form of the stigmas. No inorganic matter should separate, either settling to the bottom or dissolving out in the water, nor should any oil separate and float upon the surface. When pressed between filtering-paper, it should not leave an oily stain. When chewed, it tinges the saliva deep orange-yellow.

On agitating 1 part of saffron with 100,000 parts of water (the Ph. It. says 1,500,000 parts) the liquid will acquire a distinct yellow color. No color is imparted to benzin agitated with saffron (absence of picric acid and some other coal-tar colors).

On drying saffron at 100° C. (212° F.), it should not lose more than 14 per cent. of its weight (absence of added water). When thus dried and ignited with free access of air, 100 parts of dry saffron should not leave more than 7.5 parts of ash (absence of foreign inorganic substances).

Under the microscope, the surface of the stigmas is seen covered with finger-shaped papillæ, commonly with large globular pollen-grains attached, and both these elements are characteristic of the powder. Numerous parenchymatic cells nearly filled with the peculiar orange-red coloring-matter can also be seen.

Austrian saffron is regarded as the best, French or Gatinais as second, Spanish as usually inferior, because of the larger portion of the style which is picked with the stigmas. Saffron is sometimes pressed into cakes—usually open to suspicion—and loose saffron is often called *Hay-saffron* in distinction from it.

Constituents.—The constituents are 7.5 to 10 per cent. of odorous volatile oil ($C_{10}H_{14}O$), gum, wax, fat, 65 per cent. of peculiar extractive, a colorless bitter principle, *picro-crocin* or *saffron-bitter* ($C_{38}H_{66}O_{17}$), of glucosidal nature, and *crocin* ($C_{44}H_{70}O_{28}$), a yellow glucoside which decomposes into the sugar *crocose* and *crocetin* ($C_{34}H_{46}O_9$), a red powder. *Polychroit* is a mixture of volatile oil, sugar, and crocin. Crocin occurs as a red powder, soluble in alcohol and diluted alkalies, scarcely in water, and not in ether. Warm concentrated potassa solution evolves from it vapors of a pungent odor; concentrated sulphuric acid produces a deep-blue color, changing to violet and brown; nitric acid colors it green, then yellow and brown. Hilger and Schiller find that upon distillation with water scarcely any volatile oil is obtainable; that in a current of carbon dioxide a little more is yielded; and that an abundance is obtained after treatment with sulphuric acid. They therefore conclude that the volatile oil is derived from the splitting up of the coloring-matter molecule (crocetin?), which they regard as identical with carotin.

Adulterations.—The occasional admixture in true saffron of considerable portions of the yellow style has been noticed above. The appearance of inferior saffron is sometimes improved by oil or by glycerin; it then leaves a greasy stain on being slightly pressed between paper. Partially exhausted (mixed with good) saffron is recognized by the lighter and more uniform color of the stigmas. The tubular florets of *Carthamus* are easily distinguished by their 5-toothed corolla and the projecting anthers with style. The styles of crocus, suitably dyed, have appeared in commerce as *feminelle*, a name also given to the dyed ligulate florets of *Calendula officinalis* L.; the latter are strap-shaped, with a 3-toothed margin, and are easily distinguished from true saffron after soaking in water, or in dilute ammonia, should the coloring-matter of the dye be insoluble

in water. The stigmas of other species of crocus are lighter colored and more deeply notched. The cut petals of the pomegranate, and the stamens of crocus and perhaps other flowers, are by the same means easily recognized from their different shape. About 1860, and again since 1870, Spanish (Alicante) saffron has often appeared adulterated with chalk, gypsum, or heavy spar, the powders having been rendered glutinous by honey and mixed with the saffron; they then become yellowish and of the appearance of pollen. Powdered emery is said to be used in the same manner. The amount of such adulteration is sometimes 20 per cent., and may be estimated by incineration. Such adulterations are detected without difficulty by throwing a pinch upon water, when the mineral matter will subside, and may be identified by appropriate tests.

By thoroughly soaking in a solution of a barium salt and then in a soluble sulphate, crystalline barium sulphate is precipitated within the cell-walls. Potassium ferrotartrate is known to be so used, and F. Daels reports that by slowly impregnating the saffron with a concentrated aqueous solution of it and drying at a low temperature 14 per cent. can be added to its weight. It increases the ash very greatly.

An article known to Indian trade as *lacka* is made by mixing with the stigmas a product obtained from the remainder of the flower, by alternate beatings, specific gravity separation in water, drying, again beating, and so on. Saffron consisting of the stigmas only is there called *Shahi*, while the styles are known as *Mongla*.

In India a false saffron is made by thoroughly washing onion-roots, cutting into small pieces, and coloring with matter extracted from the buds of the *Nyctanthes arbortristis* L., or *Sad-tree* (Fam. *Oleaceæ*). Although this practice pertains to India, the product is very likely that referred to by Cesare Ghecete, as yielding a spurious saffron found in Spain.

Action and Uses.—Saffron has practically been abandoned by practitioners, but is occasionally employed in flatulent dyspepsia. It was formerly highly recommended as an anodyne, antispasmodic, and emmenagogue, and employed in the treatment of asthma, spasmodic cough, and dysmenorrhœa. In the form of an ointment it has been recommended as a palliative for hemorrhoids, and a collyrium of crocus may be tried in subacute and chronic inflammations of the conjunctiva. An infusion of the drug is frequently employed by the laity to promote exanthematous eruptions.

The dose of saffron is from 5 to 30 grains (0.30–2 Gm.). An infusion may be made with 2 drachms (8 Gm.) of saffron to 1 pint (480 Cc.) of boiling water, of which 4 fluidounces (120 Cc.) may be given at intervals of half an hour or an hour.

Allied Drugs.—The flowers of *Tritonia aurea* Pappe (*Crocosma a.* Pl.), of central and southern Africa, yield a coloring-matter very similar to that of saffron, and have been proposed as a substitute. This coloring-matter is more soluble in dilute alcohol and in alkaline solutions than in water. The partly dry, aqueous extract gives with sulphuric acid a blue coloration passing into violet, as does that of saffron (Heim).

An orange-yellow powder consisting of dinitro-naphtol and tropæolin, odorized with a little saffron, has been produced in France under the name of *Algerian saffron*.

GARDENIA GRANDIFLORA Lour., G. FLORIDA L., and G. RADICANS Thunb. (Fam. *Rubiaceæ*).—These shrubs are indigenous to eastern and southern Asia, and produce obconical 4- or 6-sided somewhat winged berries, which attain a length of 4 Cm. (1⅝ In), and contain numerous flat and finely pitted seeds imbedded in a red pulp. The coloring-matter of the latter, according to Rochleder and L. Mayer (1858), is identical with that of crocus. The fruits are regarded as possessing demulcent and refrigerant properties, and are largely used in the East for dyeing yellow.

CRUCIFERÆ.—The Mustard Family.

Genera more than 200, species about 1500, chiefly herbs, of the temperate or subtropical regions of both hemispheres. Except as regards the fruit-structure, the family is a most natural one in all respects. The well-known food-plants, cabbage, cauliflower, turnip, colza, kale, etc., are among the most important of cultivation. The specific distinctiveness or identity of some of these plants is subject to great difference of opinion. *Brassica oleracea* L., native of Europe, yields the ordinary *Cabbage* (*Sea-cabbage* or *Sea-kale* in the wild state), and the *Cauliflower*, *Borecole*, *Brussels sprouts*, and *Kohl rabi*, are now generally accepted as being mere cultivated varieties of it. *B. campestris* L., also of Europe, also yields a variety of cabbage, but is better known as *Colza*, *Naves*, *Navette*, or *Nape*. It appears probable that

the turnip comes from a distinct species, *B. Napus* L., although the view is not wanting that this, too, is merely a variety of the last-named species. The *Radish, Raphanus sativus* L., native of Asia, is perhaps to be regarded rather as a condiment or relish than as a food proper.

The seeds of a number of the above-named species yield important fixed oils, similar to that of mustard (see *Oils of Rape* and *Cŏlza*, under OLEA PINGUIA).

The medicinal constituents and properties of the *Cruciferæ* are almost perfectly typified in the mustards (see SINAPIS), as representing the more powerful substances, and in the *Horseradish* and *Scurvy-grass* (see ARMORACIÆ RADIX), as representing the milder drugs. A similar class of compounds permeate the family, imparting pungent and biting properties in greater or less degree, and causing a large number of species to be employed internally as stomachics, carminatives, laxatives, diuretics, antiscorbutics, antispasmodics, and general stimulants, or externally as counterirritants, vulneraries, and mild antiseptics. Some are so active as to be, like mustard, poisonous if improperly employed. Of these, a number have been found to contain active alkaloids or other bitter constituents.

Beyond these general statements, little is called for except an enumeration of those species which have been commonly employed as drugs.

Capsella.—Next to mustard, horseradish, and scurvy-grass, this is the most important drug of the family. It is the fresh or dried herb of *Bursa Bursa-pastoris* (L.) Britton (*Thlaspi B.* L.; *Capsella B.* Medic.), the *Shepherd's-* or *Lady's-purse, Witches' pouches, Mother's-heart, Blind-weed, Casse-weed*, E.; *Hirtentaeschlein, Saeckelkraut, Gaensekresse*, G.; *Bourse á pasteur, Mollette*, Fr.; medicinally known as *Herba Capsellæ* or *Herba Bursæ Capsellæ*, a low annual of Europe, established as one of the commonest garden-weeds of the United States. The stem is slender, smooth except at the lower part, 3 to 6 Dm. (1 to 2 Ft.) long, usually sparingly branched; leaves chiefly radical, 5 to 15 Cm. (2 to 6 In.) long, oblanceolate, almost invariably more or less pinnatifid, the few stem-leaves much smaller, lanceolate, the base clasping and auricled; flowers racemed along the entire length of the slender branches, white, very small, followed by a peculiar, strongly flattened pod of about 5 to 8 Mm. ($\frac{1}{5}$ to $\frac{1}{3}$ In.) long and broad, triangular, notched at the summit, 2-celled, the partition crossing the narrower diameter, the seeds 10 to 12 in each cell. The odor is peculiar, rather disagreeable, not pungent; the taste aromatic and biting. It contains a peculiar volatile oil, closely similar to, if not identical with that of mustard, and a resin to which part of the biting taste is probably due. The drug has important uses among the eclectics as a diuretic, emmenagogue, and antirheumatic, and is an excellent application to unhealthy sores.

The following species are very similar in their nature to *Capsella*, and are more or less used as "cresses" and as antiscorbutics:

Roripa Nasturtium (L.) Rusby (*Sisymbrium N.* L.; *Nasturtium officinale* R. Br.), native of Europe and Asia, widely cultivated and naturalized, is the true *Watercress* or *Brown cress, Brunnenkresse, Cresson de fontaine*, or *Derro*. *R. palustris* (L.) Bessey (*Sisymbrium amphibium palustre* L.; *Nasturtium p* DC.; *N. terrestre* R. Br.), having the same range, is the *Yellow* or *Marsh watercress*.

The *Lepidiums* grow with, and are very similar to *Capsella*, but are distinguished from it by the possession of oval or rounded, though similarly small and flattened pods, a solitary seed in each of the 2 cells. That which has been most used is *L. sativum* L., the *Garden-cress* or *Pepper grass, Sauce-alone* or *Poor man's pepper, Gartenkresse, Cresson Alenois*, or *Cresson des jardins*. *L. Virginicum* L. and *L. apetalum* W. (*L. intermedium* Gray) are very similar common weeds of America, and are known as *Wild pepper grass*, the latter called *Lentijilla* in Mexico. *L. Iberis* L., of Europe, is also commonly known as *Pepper grass, Pfefferkraut, Iberiskresse*, or *Passerage iberide*. It has an ovate and acute pod, while that of *L. sativum* is oval and notched. *L. latifolium* L., the *Broad-leaved pepperwort*, is distinguished by its much broader and less toothed or pinnatifid leaves.

Cardamine pratensis L., the *Herba Nasturtii pratensis, Cuckoo flower, Wiesenkresse, Kukuks-kraut, Cresson des pres*, of Europe and Asia, rare in the United States; *C. amara* L., the *Bitter cress*, and *C. hirsuta* L., the *Small* or *Hairy bitter cress*, are also employed. *C. amara* combines distinct bitter with the ordinary pungent properties of the group.

Barbarea vulgaris R. Br., the *Yellow scurvy-grass, Winter-cress* (*Winterkresse* G.), *Herbe de Sainte-Barbe*, and the *B. præcox* R. Br., are considerably cultivated as land or garden cresses, and, especially the former, are very largely naturalized weeds in the United States. *Senebiera didyma* Pers. is the *Wart-cress* or *Swine-cress; Arabis lyrata* L., the *Rock* or *Wall cress*.

Sisymbrium officinale (L.) Scop. (*Erysimum o.* L.) is the *Bank-cress, Hedge mustard* or *Scrambling rocket, Wilder senf, Hederich, Velar, Tortelle, Herbe aux Chantres*, and is a very common and homely yellow-flowered weed of roadsides and waste places. The seeds are very similar in composition and properties to mustard. *Alliaria Alliaria* (L.) Britton (*Erysimum A.* L.; *Sisymbrium A.* Scop.; *Alliaria officinalis* And.) occurs only sparingly in America, and is the *Garlic-* or *Poor man's mustard, Hedge-garlic, Leek-cress, English treacle*, or *Poor man's*

treacle, Knoblauchkraut or *Alliare commune.* The herb, and especially the seeds, have, in addition to mustard-like properties, a distinctly alliaceous odor and taste.

Thlaspi arvense L. and *T. campestris* L., of Europe and Asia, are known and used under the names *Penny-cress, Mithridate mustard, Bauernsenf, Feldkresse,* and *Thlaspi champetre,* their seeds combining the odors and tastes of mustard and garlic, as in hedge mustard.

Two species of *Iberis—I. umbellata* L. (*I. coronaria* Don.) and *I. amara* L.—contain glucosides which depress the heart and more or less paralyze the nervous system. Their seeds also contain a markedly poisonous glucoside, soluble in water and precipitated by sodium sulphate. They have been used since ancient times as antirheumatics and antispasmodics. The common *English wallflower* also contains two alkaloids, *cheiranthine,* which acts as a heart poison, and *cheiranine,* which paralyzes the nervous system.

Various species of *Dentaria* (*Pepper root* or *Toothwort, Zahnwurz, Dentaire*), some of Europe and Asia, some of America, have peppery-tasting roots.

The herb of *Anastatica hierochuntica* L., the *Rose of Jericho,* and one of the plants to which the name *Resurrection plant* has been applied, is found in the Levant. Although possessing slight stimulant properties, its use is chiefly fanciful.

A kind of indigo is yielded by two species of *Isatis.*

Tropæolum (Fam. *Balsaminaceæ*).—This beautiful and interesting genus of tropical American plants contains many species which are permeated by pungent constituents similar to those of the *Cruciferæ,* on account of which the unripe fruits are pickled and used as a delicious relish, similar to horseradish and capers. These fruits, as well as the leaves, are valued also as antiscorbutics. The most common species so used is *T. majus* L., the *Garden nasturtium* or *Kapucinerkresse. T. pentaphyllum* Lam. is known in Chile, where it is largely so used, as *Chagas da Miuda. T. tuberosum* R. et P., of the Andean region, yields a starchy and edible tuber.

CUBEBA, *U. S.*—Cubeb.

Cubebæ, P. G.; *Cubebæ Fructus,* Br.; *Fructus* (*s. Baccæ*) *cubebæ, Piper caudatum, Tailed pepper, Cubebs,* E.; *Cubèbe, Poivre à queue,* Fr.; *Kubeben,* G.; *Pepe cubebe,* It.; *Cubebas,* Sp.; *Pimente Cubebe,* Port.

The dried unripe, but fully grown fruit of *Piper Cubeba* L. f. (*Cubeba officinalis* Raf.—Fam. *Piperaceæ*).

Origin.—A dicœcious, woody climber, native and cultivated in the East India islands, closely related to the black pepper, and bearing its fruit in loose spikes 1 or 2 inches

Fig. 149.

Cubeb (after Planchon and Collin) (× 3½).

Fig. 150.

Cubebs upon the stalk (Nat.).

long. Attempts have been made to cultivate it in various other tropical regions, but have not proved successful. The so-called "stem" of the cubeb is in reality the base, or *thecaphore,* of the fruit, which develops during its growth. The stem, which is required to be sifted out and rejected, is the rachis of the spike. The fruits are collected while still of a green color, and are dried with great care.

Description.—From 1 to 1.3 Cm. (⅔ to ½ In.) long, blackish-gray, internally whitish; upper portion globoidal, 4 to 5 Mm. (⅛ to ⅕ In.) in diameter, reticulately wrinkled, consisting of a thin crustaceous endocarp enclosed by a thin sarcocarp and containing one basally attached seed; lower stem-like portion about 6 to 8 Mm. (¼ to ⅓ In.) long, cylindraceous, continuous with the globoidal portion; fruit brittle, strongly and peculiarly aromatic, and of a somewhat bitter and pungent taste.

Upon treating the crushed or powdered fruit with sulphuric acid, a crimson coloration results.

The ash should be under 8 per cent., and is usually less than 7 per cent.

Structurally, cubeb possesses the following tissues, from without inward: (1) epidermis, of a single layer of cubical cells; (2) a subepidermal layer, usually of a single row of thick-

walled stone-cells; (3) the mesocarp of many layers of thin-walled cells containing starch and crystals of cubebin, and with some larger cells filled with oil, their walls suberized and with fibrovascular bundles in the basal portion; (4) the endocarp or stone, consisting of 1 or 2 irregular layers of very large stone-cells, their long axis mostly radial; (5) the seed, which more or less completely fills the cavity according to the degree of ripeness. In a good cubeb it should about three-fourths fill it.

The light-brown powder displays all the above elements, besides free starch-grains, oil-globules, and crystals. The starch-grains are very small, rarely exceeding 5 mikrons in diameter, simple or compound, and much resembling those of black pepper. The crystals are in stellate masses and are very fine and feathery.

Constituents.—Cubeb yields 5 to 15 per cent. of volatile oil (see OLEUM CUBEBÆ), 1 to 3.5 per cent. of cubebic acid, 2.5 to 3.5 per cent. of indifferent resin, 1 per cent. of fatty oil, 8 per cent. of gum, and 0.4 to 3 per cent. of cubebin. *Cubebic acid* ($C_{13}H_{14}O_5$ or $C_{25}H_{30}O_7.H_2O$) is an amorphous yellowish mass, soluble in alcohol, ether, chloroform, and alkalies. The resin is amorphous, slightly soluble in ether and chloroform, and freely so in caustic alkalies and alcohol. *Cubebin* ($C_{10}H_{10}O_3$) occurs in odorless bitter needles or scales, freely soluble in boiling alcohol and chloroform. It forms most of the deposit from official oleoresin of cubeb, and is inert medicinally.

Adulteration and Substitution of cubeb have been practised upon a very extensive scale, and by the use of a great variety of articles. Supplying small and immature fruits, sifted out from the larger ones, is properly to be regarded as an act of substitution. This powder is lacking in the structural elements of the seed and exhibits a scarcity of the cubebin crystals. The use of the stalks (rachis) has probably been resorted to upon a more extensive scale than that of all other forms of adulteration combined. This powder is distinguished by its large amount of fibrovascular tissue. It yields 7 to 10 per cent. of ash, its admixture thus increasing the ash percentage of cubebs.

The evidences of specific adulteration with spurious fruits, in the entire condition, may be summarized as follows: The possession of a stem which is a true pedicel, or ripened flower-stem, rather than a thecaphore or narrowed fruit-base (*Rhamnus* fruits); a stem which is very short—less than one-half the length of the body—or wanting (black pepper and *Litsea citrata* (Nees) Blume,—*Tethrantus c.* Nees, this latter false cubeb having been long erroneously referred to *Daphnidium Cubeba* Nees, and being distinguished by its strong odor of lemon, due to its volatile oil containing 30 per cent. of citral, and containing the alkaloid *lauro-tetanin*); a stem which is very long—regularly twice or more the length of the body and much thickened at the free end (*Piper mollissimum* Blume); a similar long and thick and strongly curved stem (*Piper crassipes* Korth.); a body distinctly branched or mucronate at the top (*Piper caninum* Blume and *P. sylvestre* Lam.), or very large—7 Mm. or more in diameter (*P. crassipes* and *P. mollissimum*), or very heavily wrinkled (young cubeb or *P. mollissimum*, the latter when crushed with sulphuric acid giving a brownish coloration). The fruit of *P. ribesioides* Wall. also gives the last-mentioned color-reaction, and has rhombic crystals in its epidermal cells. *P. Clusii* (*Cubeba C.* Miq.; *Piper Afzelii* Lindl.), the *Ashantee* or *African pepper* or *cubeb*, has the taste of black pepper, and its tincture gives a carmine-red color with sulphuric acid; *P. crassipes* is bitter and gives a yellow color with sulphuric acid. *Padang cubeb*, its origin unknown, has the long stone-cells of the endocarp elongated tangentially instead of radially, as they mostly are in the genuine. In the Japanese *Carbamo berries* the stone-cells are few and small.

Pharmaceutical Preparations.—FLUIDEXTRACT OF CUBEB, U. S. P.; OLEORESIN OF CUBEB, U. S. P.; TINCTURE OF CUBEB, U. S. P.

Action and Uses.—Cubebs are stimulant, carminative, and stomachic. Given in moderation they excite a sense of warmth in the gastro-intestinal tract, augment the secretion of urine, to which they impart a peculiar odor, and stimulate the bronchial mucous membrane. Large amounts act as a circulatory stimulant, and may occasion headache, vertigo, nausea, and purging. Cubebs may be successfully employed in the treatment of gonorrhœal urethritis in both the male and female, but it should not be given in the very early stages. It has been given also in prostatic abscess, chronic inflammations of the vesical neck accompanied by tenesmus, chronic cystitis, nocturnal incontinence of urine, and in chronic bronchitis. In susceptible individuals its administration sometimes produces an exanthematous eruption. The powdered drug may be

given in doses of from 1 to 3 drachms (4–12 Gm.), several times daily. The volatile oil may be given in doses of 10 minims (0.6 Cc.), either in capsule or emulsion; or the oleoresin may be substituted, and given in capsules (see OLEORESINA CUBEBÆ) in doses of from 10 to 30 minims (0.6–2 Cc.).

CUCURBITACEÆ.—The Gourd or Cucumber Family.

The properties of this peculiar family of nearly 100 genera and about 500 species of tendril-bearing, prostrate or climbing vines, are well illustrated in our accounts of BRYONIA, COLOCYNTH, and ELATERIUM. The family is permeated by constituents similar to those of the drugs named, and the properties agree accordingly. The fruits and the fleshy roots of many species are richly nutritious, and very commonly grow under conditions calling for special protection against their consumption by hungry animals, such protection being well secured by the presence of the intensely bitter, promptly purgative, and more or less poisonous principles referred to above. Scarcely any other family of plants is so uniform in its physiological actions, so that a discussion of the properties of the several drugs becomes rather one of the degree than of the kind of activity. Laxative or purgative properties usually reside in most of the plant-parts. With the purgation, and similarly produced, there is more or less diuresis; but distinct diuretic properties are usually present in the seeds, and to some extent in the pulp of such fruits as the melons; this quite aside from such effects produced by their large percentage of water. The seeds of many, like Pepo (which see), are active anthelmintics. So important are the edible fruits of this family that the following enumeration of the more important ones may not be out of place:

Cucurbita Pepo L., the common *Pumpkin*, presenting a number of varieties ranked by some botanists as species; *Cucurbita maxima* Duchesne, of tropical Asia, the *Winter* or *Turban squash*, *Vegetable marrow* or *pompion* of England; *C. moschata* Duchesne, the *Crook-neck squash*; *Citrullus Citrullus* (L.) Karst. (*Cucurbita C.* L.; *Cucumis C.* Ser.; *Anguria C.* Blakw.; *Citrullus vulgaris* Schrad.; *C. fistulosa* Stock.), the *Watermelon*, native of Asia; *Cucumis Melo* L., the *Melon* or *Muskmelon*, native of Central Asia. The botanical relationship of the several strongly marked varieties of melon is a subject on which there is great difference of opinion, the following being regarded as species by some authorities, by others merely as varieties of *C. Melo*: *C. Cantalupensis* Haberl., of Armenia, the *Cantaloupe melon*; *C. deliciosus* Roth. (*C. maculatus* W.), the *Melonecto del olor* of tropical America; *C. Dudaim* L., the *Apple melon* of Persia; *C. utilissimus* Roxb., the *Kankum* of Bengal; *C. Chate* L., the *Egyptian melon*; *C. flexuosus* L., the *Serpent melon*. At least half a dozen other members of this genus yield edible fruits. *Cucumis sativus* L., the *Cucumber*, *Gherkin*, *Gurke*, *Concombre*, is a native of Asia; *Lagenaria Lagenaria* (L.) Lyons (*Cucumis L.* (L.); *Cucurbita Siceraria* Moll.; *Lagenaria vulgaris* Ser.), the *East Indian calabash*; *Sechium edule* Sw. (*Chayota e.* Jacq.), the *Choco* or *Chayote* of tropical America; *Apodanthera pedisecta* (L.) Arn. (*Momordica p.* L.; *Anguria p.* Nees et Mart.); *Zanonia Indica* L., the *Chirpota*, *Dirghapatra*, or *Kuntali*, of the East Indies; *Acanthosicyos horrida* Welw., of Africa; *Coccinia Indica* W. et A. (*Momordica monadelpha* Roxb.; *M. Pavel* Dennst.; *Cucumis P.* Kost.; *Bryonia cordifolia* L.; *B. grandis* L.), the *Kunduri*, *Telakucha*, *Gholi*, *Vimba*, etc., of India.

A complete account of the hundred or more species which are used medicinally is impracticable, but the following are so commonly employed in their respective homes that, if not already so, they are at any time liable to find a place in our materia medica.

Purgatives. *Melon-root.*—The root of the common melon is purgative and, in large doses (7 to 10 grains, 0.5–0.7 Gm.), is said to be a certain emetic, the active and bitter principle (glucoside?) having been called *Melon-emetin*.

Tayuya.—The root of *Trianosperma ficifolia* Cogn., said to contain the alkaloids *trianospermine* and *trianospermatine*, as well as the amaroid *tayuyin*, and being one of the several Brazilian drugs used under the name *tayuya*, and that of *T. dermaphylla*, are much used purgatives in South America. *Cayaponia Martiana* DC., besides being called tayuya, is known as *Abohna* or *Abohrinha do mato*, a much used drug for a great variety of disorders. The root of *Cayaponia globosa*, the *Silva Manso* of Brazil, is said to owe its activity to the alkaloid *cayaponine*, $\frac{1}{10}$ grain of which is said to purge without griping.

The large, hard, fleshy roots of several species of *Micrampelis* Raf., of the Rocky Mountain and Pacific Coast region, especially *M. fabacea* (Naud.) Greene (*Echinocystis f.* Naud.; *Megarhiza Californica* Torr.), are somewhat employed. The species named have yielded the bitter glucoside *megarhizin* and the resin *Megarhizitin* (Heamy), and the saponin-like substance *megarhin* (Young). A similar root of the great Central Plains, *Cucurbita fœtidissima* H. B. K., the *Wild colocynth* or *Wild pumpkin*, *Buffalo gourd*, or *Man-in-the-ground*, is also somewhat used. The rhizome of *Microsechium Helleri* Cogn., the Mexican *Chichicamole* or *Quilamole*, has a composition very similar to that of megarhiza. It is an emetico-cathartic poison, producing great depression of the nerve-centers. The root of *Corallocarpus epigœus* B. et H.

(*Bryonia e.* Rottb.), the *Karos-nai*, *Chilihinda*, or *Addas-gadda*, of India, is there used as a substitute for bryonia. The root of *Wilbrandtia scabra* Mart., of Brazil, and those of many species of *Melothria*, are similarly employed.

Cucumis Fruits.—The fruits of *Cucumis trigonis* Roxb. (*Karit*,—*C. pseudo-colocynthis* Royle), *C. Hardwickii* Royle (the *Hill-colocynth* of India), and *C. prophetarum* L., of Arabia, the last named containing the bitter substance *prophetin*, which occurs also in elaterium, are largely employed as purgatives. A less bitter variety of karit is said to be eaten after the removal of its bitter principle by maceration in water. *C. myriocarpus* Naud., of South Africa, is used in the form of the fruit-pulp, 20 grains having been found to produce nausea and purgation after several hours. Larger quantities produce vomiting, with some blood and considerable salivation. Its active principle has been called *myriocarpin*.

Luffa Fruits.—*Luffa operculata* Cogn. is largely used as a cathartic in Brazil. Peckolt states that for dropsy a fruit is boiled for some time, the pulp strained and beaten to a froth, and a tablespoonful given every half hour until vomiting or purging occurs. It is also made into a rude tincture by standing the sliced fruit, in rum, in the sun for some days. The fruit of *L. echinata* Roxb., of India, is similarly employed. It contains a bitter principle almost, if not quite, identical with colocynthitin. The fruit of *Luffa acutangula* (L.) Roxb. (*Cucumis a.* L.) the *Karvi-turai* of India, is active as a cathartic, and its leaves and fresh juice are applied as a vulnerary. After the removal of their pulp by maceration, the fibrous frames of the fruits of various species of Luffa, especially of *L. Luffa* (L.) Lyons (*Momordica L.* (L.); *L. Ægyptiaca* Mill.; *Turia sativa* Forsk.; *Poppya Fabiana* Koch), constitute the well-known *Dish-rag gourd*, *Gourd towel*, or *Vegetable sponge*.

The emetico-cathartic and anthelmintic properties of *Fevillea cordifolia* L. (*F. scandens* L.; *F. punctata* Poir.), the *Nhandiroba*, *Noix de serpent* or *Boite à savonette*, of tropical America, appear to reside in its essential oil.

Anthelmintics.—The root and seeds of *Melothria scrobiculata* DC. (*Bryonia s.* Hochst.), the *Taffafala* of Abyssinia; the seeds of *Sicydium monosperma* DC. (*Fevillea m.* Vell.), the *Castante do Jabota* of Brazil; of *Ampelosicyos scandens* Thou., and *Talfairia pedata* Hook. (*Joliffa Africana* DC.), both of Zanzibar, and of *T. occidentalis* Hook., of West Africa; the leaves and fresh juice of *Momordica Charantia* L., the *Karela*, *Kurla*, or *Papari* of India, and everywhere introduced into tropical America; the fruit of *M. anthelmintica* Schum., of Malabar; the oil of the seed of *M. Balsamina* L. (*Ku-kwa*); the seed of *Cucurbita Melopepo* L., called in China *Nun-kwa* and *King-kwa;* the fruit of *Trichosanthes Anguina* L. (*Cucumis A.* L.), of China, and other species of *Trichosanthus*, the seed of *T. pubera* L. (*T. palmata* Roxb.; *T. laciniosa* Wight.; *T. cordata* Roxb.), being very poisonous.

Other Uses.—The seeds of *Crua* or *Melao do Babelo* (*Sicana odorifera* Naud.), of tropical America, are used as a powerful stimulating emmenagogue; those of *Momordica Charantia* L. are credited with aphrodisiac properties. The root of *Trichosanthes trifoliata* (L.) Bl. (*Momordica t.* L.) is used as a soap-root. The fruit of *Momordica Balsamina* L. (by many regarded as identical with *M. Charantia* L.), the common *Balsam-apple* of cultivation, are often preserved in alcohol, and the pulp then applied as a vulnerary.

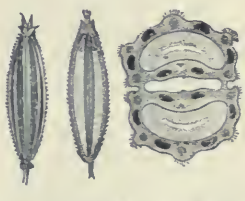
CUMINUM.—Cumin.

Fructus cumini (*cymini*).—*Kreutzkümmel*, *Mutterkümmel*, *Römischer* (*langer*, *scharfer*, *Hafer*, *Kram*, *Pfeffer*) *Kümmel*, G.; *Cumin*, Fr.; *Comino*, Sp.

The dried ripe fruit of *Cuminum Cyminum* L. (Fam. *Umbelliferæ*).

Origin.—A white-flowered annual, about a foot in height, native of northern Africa, and cultivated for its fruit, chiefly in the Mediterranean region. The best cumin comes from Malta and Morocco, and arrives in London during late August and September.

FIG. 151.



Cumin: fruit and longitudinal section, ×3; transverse section, ×8.

Description.—Of 2 carpels, united or separate, each about 6 Mm. (¼ In.) long, nearly a third as broad, and nearly as thick as broad, oblong, nearly straight, narrowed toward both ends and slightly pointed at the summit; gray-brown, or yellowish-brown; bearing 5 strong and coarse ribs alternating with 4 less elevated ones, all rough-hairy, or the 5 primary ones smoothish; oil-tubes 6; odor and taste strongly aromatic, peculiar, though somewhat resembling caraway.

It is very prone to the attacks of insects, which leave only the shell.

Constituents.—With about 8 per cent. each of fat and gum, and 13 per cent. of resin (Bley), cumin contains 3 or 4 per cent. of volatile oil (see OLEUM CUMINI).

Action and Uses.—Cumin fruit is a stimulating aromatic stomachic, and may be employed like the other umbelliferous fruits in the treatment of certain gastric and intestinal conditions when associated with nausea and flatulence.

The dose of the powdered drug is from ½ to 1 drachm (2–4 Gm.). The volatile oil is most commonly administered (see OLEUM CUMINI).

CUPRI SULPHAS, *U. S., Br.*—Copper Sulphate.

Cuprum sulfuricum, P. G.; *Cuprum vitriolatum.*—*Cupric sulphate, Blue vitriol, Bluestone*, E.; *Vitriol bleu, Sulfate de cuivre*, Fr.; *Kupfervitriol, Blauer Vitriol, Schwefelsaures Kupfer (Kupferoxyd)*, G.; *Solfato di rame*, It.; *Solfato de cobre*, Sp.

Formula, $CuSO_4.5H_2O$. Molecular weight, 247.85.

It should contain not less than 99.5 per cent. of pure copper sulphate.—U. S.

Preparation.—Blue vitriol is obtained on a large scale from the native (*copper pyrites*) or artificially prepared sulphide by converting it through oxidation into the sulphate; for this purpose the sulphide is obtained by heating sheet copper to redness and throwing sulphur upon it. The water accumulating in copper-mines contains the sulphate in solution, formed by oxidation of the native sulphide. The iron contained in this is removed either by digesting with copper oxide or carbonate, or by evaporating to dryness and heating until the iron salt is decomposed. The same salt is formed also in the preparation of sulphurous acid from copper and hot oil of vitriol, and in the extraction or purification of silver by precipitating this metal from its sulphuric acid solution by means of copper; also by dissolving in weak sulphuric acid (chamber acid) the black scales obtained in coppersmithing.

Purification.—Copper sulphate cannot by recrystallization be separated from the sulphates of the allied and of the alkali metals, owing to the formation of double salts. The so-called *double vitriol* (*vitriol de Salzbourg*, Fr.; *Doppelvitriol*, G.) contains 70 to 80 per cent. of ferrous sulphate, and the *vitriol mixte de Chypre* contains zinc sulphate; these were formerly, but now are rarely, employed in the arts. If iron alone is present, it may be conveniently removed by oxidizing with nitric acid and digesting the solution with barium carbonate; ferric hydroxide and barium sulphate will be precipitated with the excess of the carbonate, and the filtrate will yield pure crystals. If contaminated with other metals, its purification will be difficult, and it is more convenient to prepare the salt directly by heating 3 parts of copper with 10 parts of sulphuric acid, or with 5 parts of sulphuric acid, 50 of water, and 4 or 5 of nitric acid.

Properties.—Copper sulphate crystallizes in transparent azure-blue, oblique, triclinic, short prisms, which are without odor, and have a disagreeable styptic metallic taste, the specific gravity 2.274, and an acid reaction. On trituration they yield a whitish-blue powder, and on exposure to a dry atmosphere they effloresce superficially. When carefully and continuously heated to 30° C. (86° F.), the salt loses 2 of its 5 molecules of water (14.43 per cent.), and is converted into a pale-blue amorphous powder. Two molecules more of water are lost at 100° C. (212° F.), while the fifth is retained until 200° C. (392° F.) is reached, when a white anhydrous powder remains (63.9 per cent.). At a still higher temperature sulphur dioxide and oxygen are given off, and a residue of black cupric oxide is left.—U. S. 1 part of the crystallized salt dissolves in about 2.2 parts of water, 400 parts of alcohol, and 3.5 parts of glycerin at 25° C. (77° F.), U. S., in 3.5 parts of cold water (Br., P. G.), and in 0.5 part of boiling water, U. S. (1 part, P. G.); very soluble in glycerin, Br. The solution has a pale-blue color, which is changed to green on the addition of a soluble chloride. Commercial blue vitriol (*Cuprum sulfuricum crudum*, P. G.) is sometimes quite impure, but there is no difficulty in finding in our market very good and pure copper sulphate.

Tests.—The aqueous solution (1 in 20) has an acid reaction on litmus-paper, leaves a red stain of metallic copper upon bright iron, gives a deep reddish-brown precipitate with potassium ferrocyanide solution, and a white one of barium sulphate, insoluble in acids, with barium chloride solution. If ammonia water be added to the solution drop by drop, a pale-blue precipitate of cupric hydroxide is formed, which redissolves in an excess of ammonia water, forming a deep azure-blue solution, leaving no trace of residue undissolved (absence of iron, aluminum, etc.). If the aqueous solution (1 in 20) be heated to boiling with an excess of sodium hydroxide test-solution until all the copper has been converted into black cupric oxide, it will yield a filtrate which, after acidula-

tion with acetic acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide test-solution after being corked at 35° C. (95° F.) for at least half an hour, either before or after making alkaline with ammonia-water (absence of arsenic, lead, zinc, etc.). If hydrogen sulphide gas be passed through 10 Cc. of the solution slightly acidulated with hydrochloric acid, until all of the copper is precipitated as sulphide, one-half of the colorless filtrate should, on evaporation, leave not more than a trace of fixed residue, nor should the other half become colored or turbid by addition of ammonia-water (limit of iron, aluminum, alkaline earths, etc.).—U. S.

Action and Uses.—In minute doses copper sulphate acts as an astringent and tonic, and in full doses causes nausea and vomiting by its irritant action upon the gastric mucous membrane. When locally applied, its action is that of a mild escharotic, and advantage of this fact has been taken in the treatment of venereal ulcers and exuberant granulations. Solutions containing from 2 to 4 grains (0.12–0.25 Gm.) to the ounce (30 Cc.) are stimulating, and not infrequently are used to promote the cicatrization of ill-conditioned sores and phagedenic chancroids.

Pencils made by fusing together 1 part of potassa-alum and 2 parts of copper sulphate, and moulding, are usually employed as a caustic, because the pure salt is efflorescent. It was formerly employed to some extent as an emetic in doses of 5 grains (0.30 Gm.), but as it is quite poisonous it is now rarely given. Should emesis not result from the first dose, a second one should not be given. Small doses were formerly employed in the treatment of chorea, epilepsy, chronic diarrhœa, and dysentery, but its internal administration has practically been abandoned. The dose is from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.), in solution.

Overdoses of copper sulphate produce violent gastro-enteritis followed by collapse. The symptoms usually appear about one hour after the ingestion of the poison, and consist at first of nausea and vomiting, the vomitus consisting of bluish liquid and tenacious mucus. At first the stools consist of the ordinary contents of the bowel, but later contain blood and mucus. Clonic convulsions and profuse ptyalism are occasionally noted, and if the patient survive longer than 24 hours marked jaundice appears. Post-mortem examination usually reveals fatty degeneration of the liver and kidneys. The treatment of the poisoning consists in the administration of yellow prussiate of potassium, eggs, and demulcent drinks; and if the patient is not vomiting, emetics may be given or the stomach-tube employed. Opium may be given to allay pain, strychnine and other stimulants to combat shock, and external heat may be employed to maintain the normal bodily temperature.

Cuprum Aluminatum, P. G.—*Lapis divinus. Aluminated copper,* E.; *Kupferalaun,* G.—It is prepared by powdering 16 parts each of pure cupric sulphate, potassium nitrate, and alum, fusing the mixture in a porcelain capsule at a moderate heat, adding a previously prepared mixture of finely powdered camphor and alum, each 1 part, stirring well, and immediately pouring upon a porcelain slab or plate to cool and harden, when it is broken into pieces and preserved in well-stoppered bottles. The *pierre divine* or *pierre ophthalmique* of the French Codex contains a trifle less of camphor. In dispensing the *aluminated copper,* it should be well triturated in a mortar with a few drops of water before the remaining ingredients are added, to facilitate solution of the camphor. A collyrium, *Collyre de pierre divine* (Fr. Cod.), is made by dissolving 4 parts of aluminated copper in 1000 parts of water, and filtering.

Cuprum Ammoniatum, *Cuprum sulfuricum ammoniatum.—Ammoniated copper, Ammoniosulphate of copper,* E.; *Sulfate de cuivre ammoniacal, Cuivre ammoniacal,* Fr.; *Schwefelsaures Kupferoxyd-Ammoniak* (*Kupfer-Ammonium, Cuprammonium*), G. Formula of crystals, $Cu(NH_3)_4SO_4.H_2O$.—Obtained pure and crystallized by dissolving copper sulphate 1 part in ammonia water 3 parts, filtering, and pouring upon the solution 6 parts of alcohol; in proportion as the latter abstracts the water from the solution prismatic crystals will be deposited. The salt will be at once separated as a crystalline powder on mixing the alcohol with the aqueous solution. Ammoniosulphate of copper has a deep azure-blue color and an ammoniacal odor; exposed to the air, it loses ammonia and gradually changes to light blue. It dissolves in $1\frac{1}{2}$ parts of cold water; the solution has an alkaline reaction and metallic taste, and on the addition of more water becomes turbid and produces a sediment. With a solution of arsenous acid a green precipitate

(Scheele's green) is produced. When this salt is heated to 150° C. (302° F.) ammonia and water are given off, and an apple-green powder remains having the composition $Cu(NH_3)_2SO_4$, being a cupro-diammonium sulphate, while the medicinal salt is a cupro-tetrammonium sulphate; this contains 27.10 per cent. of ammonia and 32.38 of oxide of copper.

Action and Uses.—Ammoniated copper is rarely employed in medicine at the present time. It was formerly given as an antispasmodic in the treatment of epilepsy, hysteria, chorea, and other nervous affections. The beginning dose is ¼ grain (0.015 Gm.), which may be gradually increased to 3 grains (0.20 Gm.), 2 or 3 times daily, immediately after eating. The symptoms of poisoning by this drug are practically those produced by CUPRI SULPHAS (which see).

A collyrium containing ammoniated copper may be used in the treatment of purulent ophthalmia and other forms of conjunctivitis.

CUPRUM.—Copper.

Cuivre, Fr.; *Kupfer*, G.; *Rame*, It.; *Cobre*, Sp.

Symbol, Cu. Usually bivalent, but also univalent. Atomic weight, 63.18.

Occurrence.—Copper, which has been known from the earliest times, is often found in the metallic state as native copper, notably near Lake Superior; occasionally it is met with in the oxidized state as black and red copper ore or as a carbonate in malachite, and frequently as sulphide in copper pyrites, copper glance, copper ore, etc. It is a natural constituent in minute quantities of some mineral springs and of many vegetable and animal organisms. The smelting process is rather complicated for many ores, and depends mainly upon the oxidation of the sulphurets by roasting and the reduction of the metal by means of charcoal or by fusing a mixture of oxide and sulphide of copper. Arsenic and antimony, which are often present, are expelled by the repeated roastings, together with the sulphur, and the iron is made to enter the slag.

Properties.—Copper is a very sonorous, malleable, and ductile metal, of a reddish color, having the specific gravity 8.92, or when hammered 8.95. It melts at a bright-red heat, first becoming brittle, and expands in volume on congealing. It is inferior to iron in tenacity or strength and in hardness, but superior to it as a conductor of electricity and heat, and in resisting the chemical action of moist air. The most important of the numerous alloys of copper are *brass*, containing about 28 to 36 per cent. of zinc; *bronze*, containing 8 to 12 per cent. of tin, and sometimes a little zinc and lead; *bell-metal*, containing 20 to 25 per cent. of tin; and *German silver*, composed of 8 parts of copper, 3½ of zinc, and 3 or 4 of nickel.

Copper is insoluble in all non-oxidizing acids in the cold and as long as oxygen of the air is excluded. In the presence of oxygen the copper is gradually changed to oxide, which dissolves in the acid. Hence it is not safe to let foods with acid juices, that have been boiled in bright copper vessels, cool and stand in such vessels, as they become contaminated with copper. Copper is acted on by hot strong sulphuric acid and readily by nitric acid, with formation of sulphur dioxide and nitric oxide, respectively. Ammonia also dissolves copper in presence of air. Iron, zinc, lead, tin, cadmium, bismuth, nickel, in the metallic state, and phosphorus precipitate copper from its solutions, but copper precipitates silver and mercury from solutions of their salts.

Copper forms two series of salts—*cuprous* and *cupric*, the former of which are of little importance. The anhydrous cupric salts are usually white, the hydrated green or blue; the soluble ones have an acid reaction, and their solutions are decomposed by iron, zinc, and the earth metals, with the precipitation of copper. Potassium hydroxide precipitates voluminous blue hydroxide, $Cu(OH)_2$, which when boiled turns black with formation of some oxide, $Cu(OH)_2 + CuO$. Potassium carbonate precipitates green oxycarbonate of copper, the precipitate turning black on boiling. Ammonia water and ammonium carbonate occasion bluish-green precipitates which dissolve in an excess, forming deep azure-blue solutions. Potassium ferrocyanide yields a brown-red precipitate, which is insoluble in dilute acids. Hydrogen sulphide separates from acid solutions brown-black copper sulphide. Potassium iodide produces a grayish-white precipitate of cuprous iodide, one-half of the iodine being at the same time liberated.

Commercial copper is now rendered chemically pure by electrolysis. Plates of copper

are suspended from the positive pole of an electric circuit in a bath of copper sulphate; the copper is slowly dissolved and deposited on the negative pole, which consists of a thin sheet of pure copper. The impurities of silver, gold, tellurium, etc., remain in the bath as "slimes," and the silver and gold obtained from these are sufficient to cover the expenses of the operation.

Action and Uses.—Metallic copper is never employed in medicine. It is stated that workers in this metal sometimes suffer from chronic copper-poisoning. The symptoms of this condition are by no means uniform, as constipation or serous diarrhœa may be present. The individual becomes anæmic and emaciated, the teeth are usually lost early in life, and a blue line may be found on the gums. Vertigo and indigestion are also early symptoms. Minute quantities of copper have been found in the blood and feces, but it is by no means certain that it is normally present in the blood.

Copper Pigments.—Bremen Blue or Bremen Green is cupric hydroxide, prepared by precipitating a copper salt with an alkali and drying the precipitate below 40° C. (104° F.). Used as a water-color, it remains blue; but if used as an oil-color it becomes green from the formation of a copper soap. Basic cupric carbonate is sometimes sold under the same name.

Brunswick Green is either copper oxycarbonate or oxychloride.

Mountain Green, or Mineral Green, is powdered green malachite or artificially prepared copper oxycarbonate.

Scheele's Green.—Copper sulphate is precipitated by a solution of arsenous acid in sodium carbonate; its composition is $CuHAsO_3$. Scheele's green is largely used as a poison for insects (see Paris green).

Schweinfurt Green, or Paris Green, is copper acetoarsenite prepared by boiling the mixed hot solutions of cupric acetate and arsenous acid. Its composition is $Cu(C_2H_3O_2)_2.3Cu(AsO_2)_2$. It is a beautiful but very poisonous pigment, and its use has been restricted by law. It is manufactured in large quantity in this country for use on potato and other fields against Colorado beetle (*Doryphora decemlineata*). It may be distinguished from Scheele's green by giving a repulsive odor of cacodyl when heated in a glass tube.

The symptoms and treatment of poisoning by these preparations are identical with arsenical poisoning (which see).

Most of these pigments are also sold under other names than those given above. As met with in commerce, they are frequently mixed with alumina or calcium and barium compounds, and thus constitute lower grades. Mixtures of chrome-yellow and Prussian blue are likewise sold under several of the above names.

OTHER COMPOUNDS OF COPPER.

Cupri Acetas. *Cuprum aceticum, Ærugo crystallisata s. destillata. Copper acetate, Copper verditer, Crystallized verdigris*, E.; *Acétate de cuivre, Verdet crystallisé*, Fr.; *Kupferacetat, Gereinigter (krystallisirter, destillirter) Grünspan*, G. $Cu(C_2H_3O_2)_2.H_2O$.—The salt may be prepared by dissolving verdigris (basic copper acetate) in wood vinegar or acetic acid, and evaporating the clear solution to crystallization; or solutions of 2 parts of copper sulphate and 3 parts of lead acetate are mixed, the liquid decanted from the insoluble lead sulphate, acidulated with a little acetic acid, and evaporated to crystallization. The salt forms deep blue-green rhombic prisms which effloresce superficially in air and have a disagreeable metallic taste. It is soluble in 15 parts of cold water, 5 parts of boiling water, and about 16 parts of hot alcohol. The solutions have a blue-green color, and change to a deep-blue color with excess of ammonia water. The crystals become anhydrous at 100° C. (212° F.). Sulphuric and other strong acids liberate acetic acid from the salt. The tests for impurities are the same as given under copper sulphate. Copper acetate is irritant and astringent. In the form of a lotion it has been employed in the treatment of conjunctivitis, aphthous stomatitis, gonorrhœa, and leucorrhœa. Internally it was formerly recommended as a remedy for scrofulosis, intermittent fever, and epilepsy, but its employment is no longer in vogue. The lotion should contain from $\frac{1}{10}$ to 1 per cent. of the drug, and the internal dose is stated to be from $\frac{1}{5}$ to 1 grain (0.013–0.05 Gm.).

Cupri Arsenis. *Copper arsenite*, E.; *Arsenigsaures Kupferoxyd*, G. $CuHAsO_3$.—Prepared as stated above (see Scheele's Green). This is used as a tonic for debilitated mucous membranes and in anæmia. It is also used in the dose of $\frac{1}{100}$ to $\frac{1}{50}$ grain (0.0005–0.001 Gm.) in cases of summer diarrhœa.

Cupri Iodidum. *Cuprous iodide*, E.; *Kupferjodür*, G. Cu_2I_2.—Obtained by adding solution of potassium iodide to a solution of copper and iron sulphates; is a white powder, insoluble in water and dilute acids, soluble in ammonia water and solution of potassium iodide. It contains 66.7 per cent. of iodine.

Cupri Nitras. *Copper nitrate*, E.; *Kupfernitrat*, G. $Cu(NO_3)_2.3H_2O$.—Obtained by dissolving copper or its oxide in 25 per cent. nitric acid, and evaporating to crystallization.

The salt is blue, hygroscopic, and easily soluble in water or alcohol. Under 21° C. (69.8° F.) the crystals formed contain 6 molecules of water. This salt does not differ materially in its physiological action from cupri sulphas, and is employed for the same conditions and in the same dose.

Cupri Oleas. *Copper oleate*, E.; *Oelsaures Kupfer*, G. $(C_{18}H_{33}O_2)_2Cu$.—Formed by precipitating a solution of castile soap with solution of copper sulphate. Greenish-blue, granular powder, soluble in ether. Used as ointment, 1 to 2 : 10 of the vehicle, as antiseptic in indolent boils and extensive granulations.

Cupri Oxidum. *Cuprum oxydatum.—Cupric oxide*, E.; *Oxyde de cuivre, Safran de Vénus*, Fr.; *Kupferoxyd*, G. CuO. Molecular weight, 78.98.—Obtained by precipitating copper carbonate by mixing hot solutions of copper sulphate and sodium carbonate, washing, drying, and heating the precipitate to red heat. It is a soft, black, amorphous, heavy powder, which dissolves in dilute nitric acid without effervescence (absence of carbonate); this blue solution may be tested for iron and other metals by ammonia and hydrogen sulphide in the same manner as copper sulphate. By precipitating a solution of copper sulphate with an excess of potassium or sodium hydroxide and boiling, a brownish-black powder is obtained having the composition $Cu(OH)_2 + CuO$ (molecular weight, 255.38); by red heat it is converted into anhydrous oxide, CuO. Copper oxide is also formed when copper is heated in air or oxygen. The blue solution of cupric hydroxide in concentrated ammonia water is a solvent for cellulose, and is known as Schweizer's Reagent.

Cuprous oxide, a lower oxide of copper, of the composition Cu_2O, is of interest because of its formation in the test for dextrose (glucose) by Fehling's Solution (which see). It is a red powder, unchangeable in air when dry, insoluble in water, soluble in ammonia water, forming a colorless solution which turns blue in contact with air. With hydrochloric acid it forms cuprous chloride.

Cupri Subacetas. *Ærugo, Viride aëris. Verdigris, Copper subacetate*, E.; *Acétate basique de cuivre, Vert-de-gris, Verdet gris*, Fr.; *Grünspan, Spangrün, Basischessigsaures Kupfer (Kupferoxyd)*, G Formula of pure verdigris, $Cu_2O(C_2H_3O_2)_2$.—Verdigris was already known to Theophrastus about 300 B. C., when it was prepared from copper and various refuse-products obtained in making wine. In the wine districts of Southern Europe, and particularly in the neighborhood of Montpellier, verdigris is prepared by the aid of the marc of the wine-press. These grape-husks are allowed to undergo the acetic fermentation, and are then stratified in earthern vessels with sheets of copper, which if new, have been previously superficially corroded by a solution of copper acetate. After having been thus kept at a temperature of 8° or 10° C. (46° or 50° F.) for 3 or 4 weeks, the plates are removed, placed upright to dry, and for the following 6 or 8 weeks are occasionally dipped into water and exposed, until the neutral acetate at first formed has been converted into a thick layer of verdigris, which is scraped off. The sheets are then replaced in the grape-husks, and the process repeated until the copper has been completely corroded. The scrapings are formed with water into cakes of convenient size and dried. The French article is blue, and has the composition, $Cu(C_2H_3O_2)_2.Cu(OH)_2 5H_2O$. Verdigris of inferior quality is said to be made in the cider districts of England in a similar manner from pommage or apple-marc, and in some places it is obtained by exposing the copper to the vapors of vinegar or pyroligneous acid or by treating impure cupric oxide with the latter. The English, German, or Swedish variety is green, and consists principally of $[Cu(C_2H_2O_2)_2]_2 + Cu(OH)_2 + 5H_2O$. Verdigris is met with in commerce in heavy and hard bluish-green masses containing a considerable number of small crystals and breaking with an earthy somewhat crystalline fracture. It varies in composition, but always consists mainly of hydrated oxyacetate of copper, and contains between 45 and 50 per cent. of cupric oxide. It is decomposed by, and but partially soluble in, water, insoluble in alcohol, but completely soluble (the impurities excepted) in ammonia and dilute sulphuric, acetic, and hydrochloric acids. Acids should produce but little effervescence, showing the absence of carbonate. The presence of chalk as an impurity is determined by the copious effervescence when dissolving a sample in warm acetic acid, and by the precipitate occurring in the solution on the addition of ammonium oxalate. The green coat formed on copper when not kept clean, and often called verdigris, is basic copper carbonate, and not true verdigris. Copper subacetate is occasionally used as a stimulant application to sluggish ulcers and as a caustic to condylomata and warts.

Cupri Sulphocarbolas. *Copper sulphocarbolate*, E.; *Paraphenolsulfosaures Kupfer*, G. $(C_6H_4(OH)SO_3)_2Cu.5H_2O$.—Obtained by interaction between copper sulphate and barium phenolsulphonate. Green prisms or needles, soluble in water and alcohol. Used externally as an antiseptic like the zinc salt, 1 : 100–200 of water. In gonorrhœa and blennorrhœa, 0.5–1 : 200 of water.

CURARE, *Fr. Cod.*

Urari, Wourari, Wourali, Woorara.

A vegetable extract, prepared from various plants, by the Indians of South America, for the poisoning of arrows.

Origin.—The use of arrow poisons is ancient and common among savages, the vegetable or animal substances employed depending upon the resources of the region and the knowledge and intelligence of the tribe. The use of such a poison under a specific name would naturally indicate a specific origin and a certain degree of uniformity in its preparation and composition. At the same time, such uniformity is not absolute. Different branches of the same tribe, or associated tribes, might be expected to employ the same name, while introducing more or less variation, in the way of improvements, into the article. Such is clearly the case with the substance under consideration. The important ingredient is certainly *Strychnos bark.* The generic identity of the strychnos plants having been recognized, the tribes of different regions have evidently employed the one or more species obtainable in their respective localities; the following have been reported: *S. Castelnœi* Wedd.; *S. toxifera* Schombk.; *S. pedunculata* Benth. (*S. Schomburghkiana* Klotsch); *S. cogens* Benth. (*Aurimara*), the last 3 in British Guiana, according to Schomburghk; *S. Gubleri* Planch.; *S. Crevauxiana* Baill., the last 2 about the source of the Rio Negro; *S. Yapurensis* Planch., on the Yapuri River, and *S. Rouhamon* Benth. (*Rouhamon Guianensis* Aubl.). With these poisonous articles are associated others, the activity of some of them being doubtful. It seems probable that substances inert, or relatively so, are introduced to impart consistency, to mislead or to maintain secrecy, or from superstitious considerations. The following additional ingredients have been named: *Cocculus toxiferus* Wedd. (?), *Eko* or *Pani du Maharao; Didelphys crancrivora* (?) (*Œne* or *Mucura-ea-ha*); an *aroid* called *Taja;* several species of *Artanthe* (?); the wood of a *Xanthoxylum* (*Manuca*); the wood or bark of *Serjania nodosa* Redlk. (*Paullinia Curura* L.), the last doubtless containing saponin; the fleshy root of a *Cissus* (*Muranna*). Extraction and concoction are performed by ingenious methods, although combined with more or less of superstition and mysticism.

Properties.—Curare is a blackish-brown extract, brittle or hygroscopic, of a very bitter taste, and almost completely soluble in dilute alcohol. Cold water dissolves about 75 per cent.; this portion, containing the poisonous alkaloids, is insoluble in ether and very sparingly soluble in absolute alcohol.

Constituents.—The variable origin of *curare* results inevitably in the variable composition which has been recorded for it. It appears, however, that the closely related species of strychnos employed agree in the possession of the 2 following alkaloids, although their relative and absolute percentages vary: *Curarine* (according to Boehm, $C_{19}H_{21}NO_4$; according to Sachs and others, $C_{18}H_{35}N$) is amorphous and yellow, yielding a greenish fluorescent aqueous solution, freely soluble in alcohol and water, less so in chloroform and amyl alcohol, insoluble in ether, carbon disulphide, and benzol; with nitric acid deep-red, with concentrated sulphuric acid carmine-red, and becoming violet on the addition of potassium dichromate; it is precipitated yellow by potassium ferricyanide and white by the ferrocyanide, sulphocyanate, and iodate, and by sodium phosphate and arsenate. *Curine* ($C_{18}H_{19}NO_3$), non-poisonous, is crystalline, precipitated by metaphosphoric acid, and yields, on treatment with methyl iodide, an alkaloid having the effects of curare. With these alkaloids there is considerable brown resin, fat, gum, clay, and red coloring-matter.

Action and Uses.—When curare is applied to the unbroken skin, no absorption takes place; but if the integument be broken, it is rapidly taken into the circulation and exerts its peculiar effects. If given by the stomach, the drug is eliminated by the kidneys almost as rapidly as it is absorbed, and unless the dose be quite large it produces no very marked effect. When given hypodermically its action is rapid and powerful. Like other members of the strychnos family, if injected into the vessels of the cord it acts as a powerful stimulant and produces exaggerated reflexes followed by tremors and convulsions. If employed hypodermically in other parts of the body, however, no such symptoms follow, as the dominant action of this drug is that of a paralyzant to the motor nerve-plates which end in the striated muscles (the heart excepted), causing more or less complete paralysis. The drug has no effect on the motor nerve-trunks or upon the muscles themselves, but it does depress the termination of nerves around ganglion-cells and causes

paralysis of the sympathetic ganglia. Curare exerts but little effect upon the heart, and the circulation remains intact long after respiration has ceased. Large quantities depress the vagus, increasing the rapidity of the heart's action, and lower blood-pressure by depressing the sympathetic ganglia supplying the peripheral bloodvessels. After the administration of curare the respirations become short, irregular, and jerky in character, and asphyxia finally results from paralysis of the respiratory muscles, because of the depression of the terminals of the motor nerves supplying them. The blood becomes venous in character, the secretions—for example, the perspiration and saliva—are sometimes augmented, and the rhythmic movements of the spleen and peristaltic action of the intestines are increased. Because of the motor paralysis produced, metabolism is interfered with and tissue-waste is greatly decreased. Less oxygen is absorbed and less carbon dioxide is excreted. Curare sometimes augments the flow of the urine, and glycogen and lactic acid are occasionally found in this secretion after its administration.

Curare is of very little importance in practical medicine. It has been employed in the treatment of epilepsy, tetanus, hydrophobia, strychnine-poisoning and other convulsive seizures, and while it will undoubtedly control the spasm it exerts no curative effect whatever.

The beginning dose of curarè is $\frac{1}{10}$ grain (0.005 Gm.), given hypodermically in a watery solution. This may be gradually increased to as much as $\frac{1}{3}$ grain (0.02 Gm.), but the latter amount should be given guardedly. The dose of curarine is stated to be $\frac{1}{100}$ grain (0.0005 Gm.). Curarine resembles digitalis in its action, and has no effect upon the motor nerves.

Other Arrow Poisons (for historical account, see Stockman, *Pharm. Jour. and Trans.*, 7, 1898, 548, 562, and 585).—Owing to the secrecy maintained by the makers of these substances, information concerning their composition is meager and often contradictory, yet their investigation has contributed much to our knowledge of poisonous plants, which knowledge constitutes the chief feature of interest in the following synopsis: It is somewhat remarkable that the genus *Strychnos* should have constituted almost the only resource of the American savages, while in the old world the *Apocynaceæ*, equally abundant and active in American tropics, should have taken first place. Strychnos has, however, especially in Asia, also held an important place in the art. The *Blay-hitam* arrow poison of the Malays has been shown to be from a Strychnos bark, though the species is unknown.

Poisons chiefly or wholly from Acocanthera.—As is so frequently, almost generally, true of useful plants, and especially of important medicinal plants, there is little that is definite or useful concerning *Acocanthera* G. Don. to be found in botanical works, and we must turn to pharmacological sources for our information. Schumann, in monographing the genera of *Apocynaceæ* for *Pflanzenfamilien*, has ignored all the important and valuable literature of pharmacy relating to these plants, and merely said "3 species, ... the *A. deflersii* Schwienf. and *A. Ouabaia* Cathal. not well enough known to me." The genus will probably be found to number a half dozen or more species, and it has been remarked that the poisonous ones are to be recognized by their bitter taste. It appears certain that at least 3 species, none of them among those recognized by Schumann, are used in African arrow poisons, the important one being *A. Schimperi* (A. DC.) B. et H. (*Carissa S.* A. DC.).

Wa Nyika (Wanika), Wakamba, and Wa Gyriama Poisons.—Fraser appears to have positively identified the last mentioned species as the source of the active constituent of this group of arrow poisons, as well as that from Arnaud's unidentified species of *Acocanthera*, and has shown it to be the same as that derived from the seed of a strophanthus which has been called *S. glaber*. This constituent has been called *ouabain*, and the present source of this commercial substance is said to be the above-mentioned seed, which yields it in much larger amount than does the *Acocanthera*. Fraser points out that since the term *ouabain* has been applied to two other bodies (from other species of *A.*), it is desirable to give to this the name *acocantherin*, and to identify it by its known source and by the following characters. He gives it the formula $C_{30}H_{46}O_{12}H_{26}$, the same as ascertained by Arnaud. A statement was at one time accepted that this substance was identical with strophanthin, but it is now known that this is not the case. Fraser describes it as crystallizing from water in colorless and transparent quadrangular plates, from alcohol in tufts or rosettes of fine needle-shaped crystals; soluble in distilled water at 13° to 15° C. (55.4° to 59° F.) to the extent of 0.93 per cent. and in alcohol (specific gravity 0.92) to the extent of 2.4 per cent., much more soluble in both at higher temperatures; insoluble in ether and chloroform. The saturated aqueous solution is tasteless and neutral. It is red, becoming green with concentrated sulphuric acid. The melting-point is 186° C. (366.8° F.). It reacts as a glucoside with dilute sulphuric acid. He finds that small and carefully regulated doses can produce a great slowing of the heart, even when the vagi are divided or when atropine has been administered. Such doses also

produce a great increase in both of the movements of the heart, with practically no effect upon blood-pressure. Large doses produce a great rise of blood-pressure, apparently dependent upon the vasomotor effect or upon the peripheral ganglia. This is different from the method in which digitalis acts. Acocantherin, however, acts powerfully upon striped muscle. Another specimen of Wanika poison, also traced to an *Acocanthera*, yielded a glucoside to which Dobbin assigned the formula $C_{30}H_{52}O_{14}$, this being one of the ouabains.

Ouabaio, Wabei, or Wabajo Poison.—A root, supposed to yield this poison, was described by Holmes as that of *A. Schimperi*, probably yielding Fraser's acocantherin, as follows: Occurring in pieces of irregular length and 18 to 40 Mm. ($\frac{3}{4}$ to $1\frac{1}{2}$ In.) in diameter, of a grayish-brown color, longitudinally and occasionally transversely fissured, the outer surface soft and spongy. On transverse section the outer layer of the bark is marked by a network of darker lines, the outer meshes showing white laticiferous ducts and dark bundles of sclerenchymatous cells, the inner layer rather similar but denser and closely adherent to the wood, which is yellowish-white, tough, minutely porous, and well marked with narrow medullary rays. The bark is more bitter than the wood. Ouabaio poison is thus very closely related to, if not identical with, the preceding group.

Ipoh or Hippo Poison.—Of this, used by the natives of Perak, there are several varieties, and it does not appear that the botanical origin of any one of them is known precisely. The varieties called *Aker* and *Aker-lampong* have been located in the genus *Strychnos*, but the species, even if described, have not been identified with sufficient certainty. The much weaker action of the second variety renders it probable that its source is not the same as that of the first. Stockman found that death resulted from an action on the heart, similar to that of digitalis, the motor nerves remaining excitable to electric stimulation for some time after death. The origin of the variety known as *Prural* is apparently entirely unknown. The idea has been promulgated that it is from a Rubiaceous plant, *Coptosapella flavescens* North, related to cinchona, but it seems highly probable that there was some error in connecting the specimen with the poison. This poison produces stiffness or death of the muscular tissue with which it comes into contact, together with local extravasation. In this it acts like the saponin group of glucosides.

Wakamba (Vakamba), Massai, and Wa Nyamiwesi Poisons.—Von Brieger isolated from Wakamba poison a body which was called *wakambin*, to which he assigned the formula $C_{29}H_{46}O_{19}$. It crystallizes in needles insoluble in ether, acetic acid, chloroform or benzene, and soluble with difficulty in cold, more soluble in hot alcohol or water, the solution lævogyre, not reducing Fehling's Solution. By long heating with mineral acids, a yellow amorphous body separates, readily soluble in alcohol and not poisonous. The portion remaining in the solution reduces Fehling's Solution. It dissolves in concentrated sulphuric acid with a reddish-brown color and green fluorescence, and gives no alkaloidal reaction. It is of extraordinary toxicity, 0.05 Mgm. being fatal to guinea-pigs of 300 Gm. weight in 50 minutes; 0.3 Mgm. per kilo being fatal to dogs. It affects the muscles sooner, but is less tetanic than Ipoh poison. It appears identical with the constituent of Wagogo poison. Schellman regarded the latter as the product of two Euphorbiaceous trees, but this appears improbable.

The Echuja poison of southwestern Africa has been referred to *Adenium Boehmianum* (Fam. *Apocynaceæ*). It contains the glucoside *echujin*. Boehm gives the following as the relative toxic doses per kilo of body-weight in the dog: echujin, $\frac{1}{140}$ grain; strophanthin, $\frac{1}{280}$ grain; ouabain, $\frac{1}{480}$ grain.

Taita, Teita, or Swahili arrow poison is of the same class and quite certainly derived from species of *Acocanthera*, as is also the Merju variety. MacPherson has found in the practical treatment of soldiers poisoned by Acocanthera arrow poisons that strychnine is a useful antidote.

Other Vegetable Arrow Poisons.—The glucoside *antiarin*, from *Antiaris toxicaria*, has been considered elsewhere. It is used as an arrow poison in different parts of the East Indies. Some of the South African natives employed the leaves of *Buphane disticha* Herb. (*Hæmanthus toxicarius* L.—Fam. *Amaryllidaceæ*), and several *Euphorbias*, together with an *Acocanthera*. In India, the tuber of *Aconitum ferox* Wall., *Rhaphidophora decursiva* Schott. (*Pothos d.* Roxb.—Fam. *Araceæ*), and *Lunaria amara* Blanco (*Rabeleisia Philippinensis* Pl.—Fam. *Rutaceæ*), are used. (See also Abrus.)

In Asia a poison called *Likir* is obtained from *Amorphophallus Prainii* Hook. (Fam. *Araceæ*). The Japanese natives (*Ainos*) are said to make use of an extract of aconite and tobacco. The natives of New Hebrides are said to secure damp earth containing the bacillus of lockjaw, with which their arrows are smeared. The use of cadaveric poisons is practised in a number of parts of Africa. The Cayapas Indians, of Ecuador, are said to use a *Solanum*.

Arrow Poisons of Animal Origin.—The Kalahari bushmen of southwestern Africa apply the entrails of a caterpillar called *Nga*. It is said that if this is drawn over a small sore, it causes the most excruciating agony, the subject dying slowly in the most violent delirium. Some Africans employ the larvæ of the beetle *Diamphidia simplex*. The bug is squeezed gradually between the forefinger and thumb until a colorless fluid exudes, which is

smeared over the head of the arrow. The action of this poison appears similar to that of snake-venom, and it appears to be a toxalbumin.

The arrow poison of the Choco Indians of the United States of Colombia is said to be obtained from a small frog of the genus *Phylobates*, and to be obtained as a yellow acrid juice which exudes from the skin of the animal when it is held over a fire. The fact that the effect of the Choco poison is identical with that of curare, and the natural improbabilities found in the above statement, militate against its acceptance.

The arrow poison used by some natives of Central Africa is said to be prepared from the bodies of red ants.

CURCUMA.—Turmeric.

Rhizoma curcumæ.—*Curcuma*, Fr., Sp.; *Souchet des Indes*, Fr.; *Kurkuma, Gelbwurz, Gelber Ingwer, Gelbsuchtwurzel*, G.

The rhizome of *Curcuma longa* L. (*C. rotunda* L.; *Amomum Curcuma* Jacq.—Fam. *Marantaceæ*).

Origin.—A perennial, reed-like plant of India, very largely cultivated in tropical countries, chiefly for the use of its rhizome as a condiment, and known only in cultivation. It is one of the most important constituents of curries, and is largely used as an adulterant of mustard and as a substitute for it in many of its uses. In the course of its preparation, it is subjected to a scalding or parboiling process, which partly hydrates its starch and converts the interior from a mealy to a pasty, or when dry a resinous, consistency and appearance. Round curcuma consists of the main rhizome; long curcuma, or fingers, of the branches.

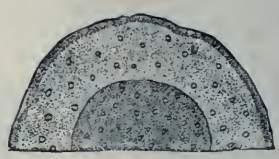
FIG. 152.

Round curcuma.

FIG. 153.

Long curcuma.

FIG. 154.



Curcuma: transverse section (×3).

Description.—From 2.5 to 5 Cm. (1 to 2 In.) in length, the "round" form oval or ovoid, flattened, about half as broad as long, and about half as thick as broad, the "long" nearly terete, somewhat narrowed toward one end, straight or curved, about one-fourth as thick as long; externally bright-yellow to grayish-yellow, with a soft, friable, mealy or dusty outer surface, or gray and smoothish, annulate with leaf-scars and usually marked with small root-scars; fracture short and smooth, with a waxy, resinous luster, gamboge-yellow to brownish-yellow, or varying to dark-red brown or nearly black, the center darker, the vascular bundles scattered throughout, most numerous near the nucleus-sheath; odor aromatic, peculiar; taste warm, aromatic, slightly bitter.

The powder is bright-yellow, and contains starch-grains ranging from 10 to 45 (mostly 15 to 30) mikrons in length, mostly ovoid, the rings conspicuous, but the hilum usually not so. They frequently cohere in masses having more or less the form of the cells from which they came.

Madras curcuma is most highly esteemed. It is bright-yellow, light-orange within, and is frequently cut to facilitate drying. *Bengal curcuma* is mostly of the round form, slender, of a deep reddish or reddish-gray, and dark within. *Java curcuma* is very similar to Bengal, but more gray without and still darker within. *Chinese curcuma* consists of many central rhizomes, with well-developed branches.

C. viridiflora Roxb., and probably other species also, yield rhizomes which are used as curcumas. From one of these is probably derived the *Cochin curcuma*, which consists mostly of sections of a large tuber, often marked with large stem-scars.

Constituents.—Curcuma contains about 1 per cent. of volatile oil, 11 per cent. of viscid oil, 0.3 per cent. of curcumin, a minute quantity of an alkaloid with crystalline salts, starch, gum, resin, and acid potassium oxalate. Curcumin ($C_{14}H_{14}O_4$) is a yellow crystalline powder of slight vanilla odor, tasteless, scarcely soluble in water, and very soluble in alcohol, ether, chloroform, and the oils. It forms a red-brown solution with alkalies. Weak oxidizing agents change it to vanillin. The carmine-colored potassium compound is insoluble in strong alcohol and ether; the zinc compound is soluble in water; the insoluble lead and silver compounds are easily altered. By boiling an alcoholic solution of curcumin with boric acid and decomposing the compound with hot water, Schomberger (1866) obtained yellow *pseudocurcumin*, which is not reddened by boric acid, and is soluble in alkalies with a greenish-gray color. Boiling as before, but in the presence of sulphuric acid, *rosocyanin* is formed, which is crystalline, insoluble in water, benzene, and ether, and soluble with a beautiful red color in alcohol. Alkalies color it blue; the solution, on boiling, turns blood-red, then yellow, and now contains pseudocurcumin.

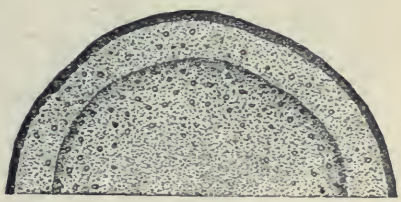
The viscid oil is partly turmerol ($C_{19}H_{28}O$), pale-yellow, aromatic, dextrogyre, of a density of 0.016 at 17° C. (62.6° F.), and boiling at 280° to 290° C. (536° to 554° F.) with partial decomposition.

Action and Uses.—Turmeric possesses slight stimulant properties, but is not used in medicine in this country. At one time it was employed in Europe in the treatment of jaundice, but its efficacy is questionable. The drug is largely used in India as a condiment, and it occasionally answers a similar purpose in America. Solutions of turmeric are occasionally employed to impart color to pharmaceutical preparations and to prepare turmeric paper. Turmeric paper is made by moistening white bibulous paper in a neutral tincture or decoction of the drug. The tincture is prepared by percolating 1 ounce (30 Gm.) of turmeric with sufficient dilute alcohol to obtain 6 ounces (180 Cc.).

Other Curcumas.—The genus *Curcuma* contains about 30 species, all of the old-world tropics. From several of them, especially *C. angustifolia* Roxb., a kind of arrow-root starch is obtained. The most important product, next to curcuma, is the following:

Zedoaria (*Zedoary, Rhizoma Zedoariæ*, P. A., P. G.; *Zittwerwurzel, Langer Zittwer, Giftheil, Zarnabac*, G.; *Zedoaire longue*, Fr.) is the rhizome of *C. Zedoaria* Rosc. (*C. Zerumbet* Roxb.; *Amomum Z.* Kurz.), the so-called *Round zedoary*, coming from *C. aromatica* Salisb. Both are East Indian plants, of similar habit to the curcuma plant, the former extensively cultivated. The rhizome, or, more properly, tuber, is terete and somewhat thicker than curcuma, and, to facilitate drying, is sliced, mostly transversely. It occurs in nearly circular (occasionally oval) disks, from 1 to 4 Cm. ($\frac{1}{2}$ to $1\frac{1}{2}$ In.) broad, and 4 to 10 Mm. ($\frac{1}{6}$ to $\frac{2}{5}$ In.) thick, the thickness almost uniform at margin and center. The edges are grayish-brown and wrinkled, the cut surfaces white or grayish-white and smoothish, with a darkish endodermal circle near the margin.

Fig. 155.



Zedoary: transverse section of one-half of rhizome.

Vascular bundles and resin-cells may be seen throughout, but the former are especially abundant toward the center. The fracture is short and more or less mealy, the aromatic odor and taste peculiar, resembling ginger, and, slightly, camphor. The starch-grains also resemble those of ginger. Round zedoary is yellow internally and appears in yellow disks.

Zedoary contains starch, gum, bitter extractive, a soft pungent resin, and a volatile oil.

CUSPARIA.—Angustura; Angustura Bark.

Carony bark; Cusparicæ cortex; Cortex Angusturæ.—Angustura Rinde, G.; *Angusture vraie*, Fr.

The bark of *Cusparia Angustura* (Rich.) Lyons (*Bonplandia A.* Rich.; *B. trifoliata* W.; *Galipea Cusparia* St. Hil.; *G. febrifuga* Baill.; *Cusparia f.* Humb.; *Galipea officinalis* Hancock.—Fam. *Rutaceæ*), a small tree of the Orinoco basin. It derives its name from the exporting locality, the "Angustura" (*Narrows*) of the Orinoco River.

Description.—In flat, curved or quilled pieces, several inches in length and 1.5–3 Mm. ($\frac{1}{16}$ to $\frac{1}{8}$ In.) thick; outer surface light yellowish to slightly orange gray, with an uneven or finely warty-scurfy and friable cork, sometimes light-gray and rather hard, or reddish-brown and smoothish when the corky layer is removed; inner surface varying from light yellowish-brown to (when long kept) reddish or dark-brown, frequently marked with transverse wavy lines, or showing blistered or partly detached portions of the thin innermost layer; fracture sharp, smooth, somewhat granular, more or less laminated, reddish-brown and resinous, except in the pale-brown corky layer, showing numerous white, glistening striæ of crystals of calcium oxalate, and minute dark-colored oil-cells; odor agreeably aromatic; taste aromatic and very bitter. The lack of sclerenchymatous tissue is regarded as distinguishing Angustura from all of its adulterants.

Fig. 156.

Angustura (Nat.).

Substitution has been extensively practised, chiefly with the bark of *Esenbeckia febrifuga* Juss. (*Evodia f.* Mart.), the Brazilian angustura, which is mostly wanting in the corky layer, has a fibrous fracture, exhibiting much sclerenchymatic tissue, lacks the white striæ, and is without aroma, although bitter. A poisonous, brucine-yielding strychnos bark was at one time accidentally substituted.

Constituents.—Angustura contains a white bitter principle, *angusturin* or *cusparin;* 1.5 per cent. of volatile oil, consisting of galipol, galipene, cadinene, and pinene; 3.8 per cent. of resin, part of which is hard and bitter and the rest soft; and 4 alkaloids: *cusparine* ($C_{20}H_{19}NO_3$), 1.5 per cent., crystallizes in needles and tetrahedrons, and forms bitter white salts sparingly soluble in water; *cusparidine* ($C_{19}H_{17}NO_3$) occurs in white needles, and yields white bitter salts; *galipine* ($C_{20}H_{21}NO_3$) is in white needles and yields yellow crystalline salts; *galipidine* ($C_{19}H_{19}NO_3$) occurs in white laminæ, and forms bitter pale-yellow salts. Some amorphous alkaloids and a glucoside await investigation. There is no tannin present, although the infusion yields a red-brown precipitate with ferric chloride and some other metallic salts.

Fig. 157.

Angustura bark: transverse section, magnified 10 diameters.

The barks of *Cusparia odoratissima* (Lindl.) Engl. (*Galipea o.* Lindl.) and *G. dichotoma* Fr. All., both of Brazil, are used like Angustura.

Action and Uses.—Angustura may be classed among the simple bitters, and may be employed in the various conditions in which they have been recommended. It may be used in atonic dyspepsia and in anorexia following convalescence from acute febrile conditions. In mild cases of intermittent fever it is supposed to possess value, but is rarely employed at the present time. Angustura has also been used with varying degrees of success in the treatment of tropical dysentery.

Angustura may be given in powder in the dose of from 10 to 30 grains (0.60–2 Gm.). An infusion (made with 50 Gm. of drug to 1000 Cc. of water) may be given in doses of from ½ to 1 fluidounce (16–30 Cc.).

CUSSO, *U. S., Br.*—Kousso; Red Cusso.

Brayera, U. S., 1880; *Flores Koso*, P. G.; *Kusso*, E.; *Kousso*, Fr.; *Koso, Kusso, Cusso*, G.; *Cosso*, It.

The dried panicles of the pistillate flowers of *Hagenia abyssinica* (Bruce) Gmelin (*Bankesia A.* Bruce; *Brayera anthelmintica* Kunth.—Fam. *Rosaceæ*). The large stems should be rejected before using.

Origin.—A handsome good-sized tree of the high and rather arid regions of Abyssinia, cultivated to some extent both for its medicinal product and its ornamental properties. Its flowers are unisexual, though more or less polygamous. Little seems to be known as to the best time for collection, though we are informed that it is collected after fertilization. Following the history of Cannabis and some other flowers having active constituents of the same general nature, we might believe that the drug would be more active before pollination. After partial drying, several of the panicles described below are compressed into a roll and tied tightly with the stem of a *Cyperus*.

Description.—Mass red-brown, hairy and minutely glandular, consisting of panicles varying from 25 to 40 Cm. (10 to 16 In.) long, a sheathing bract at the base of each branch, and 2 rounded bracts near the base of each flower; calyx having a cup-shaped, hairy tube, and bearing on its back a circle, resembling an outer calyx, of 5 thickish and rigid, spreading, obovate, purple-veined bracts, which are larger than the 5 thinnish, usually shrivelled and incurved, oval calyx-lobes; petals 5, delicate, whitish, oblong, much shorter than the sepals, caducous, hence often wanting in the drug; stamens aborted; pistils 2, the 1-ovuled ovoid ovaries concealed in the calyx-tube, shorter than the styles, which are exserted; stigmas broad, hairy; odor slight, agreeable; taste bitter, acrid, and nauseous.

Loose flowers, usually largely staminate, should be rejected.

Under the microscope, the surface is seen to bear short glandular-headed hairs of several distinct types, besides long, slenderly tapering 1-celled hairs with dilated hollow bases, and both of these elements are conspicuous and characteristic in the powder. The ash should not exceed 5 per cent.

FIG. 158.

Hagenia abyssinica Gmelin: *A*, lowest branch of panicle (⅔ Nat.); *B*, staminate flower; *C*, section of pistillate flower (×4).

It is believed that much of the disrepute of this very valuable remedy is due to the impure quality of the drug, resulting chiefly from the presence of the male flowers. In the entire condition these are easily distinguished, the mass having a pale greenish-brown color, the official being thus distinguished as *Red cusso*. An examination of the structure is easy and the result positive. In the powdered condition, detection is by no means easy. The presence of pollen-grains is not sufficient, since more or less of them are affixed to the stigma and other parts of the pistillate flowers. Their great abundance in the powder of the staminate flowers is fairly characteristic. The calyx-tissue of the male flowers is of a greenish-yellow, and this can be detected in the powder. The disre-

pute of the drug is also largely due to the general practice of powdering the inert stems with the flowers. English authorities claim much better results from the finely powdered drug suspended in some thick liquid, as syrup, than from any extracted preparation.

Constituents.—Cusso yields a small quantity of tannin, volatile oil, crystallizable acid, bitter resin, *protokosine*, an inactive crystalline body, and 3 per cent. of *kosin*. This substance ($C_{31}H_{38}O_{10}$), also called brayerin, kwosein, and koussin, is a yellowish-white, indistinctly crystalline body of bitter and acrid taste, sparingly soluble in water, and freely so in alcohol, ether, and alkalies. The amorphous kosin of commerce is more active than the pure principle, probably on account of the resin it contains. Kondakor and Schatz (1900) distinguish an amorphous glucoside (?) *coussin* ($C_{26}H_{41}O_5$), and crystalline *cosine* ($C_{22}H_{32}O_7$), which, with dilute sulphuric acid, yields isobutyric acid and an unidentified body.

Action and Uses.—Cusso is exclusively employed as a tænicide. It has been used in Abyssinia for many years, but it is stated that the drug is very severe in its action, producing nausea and vomiting, and at times failure to purge. The worm is expelled in segments, and, as is the case with all similar drugs, the head is not always discharged. By some the drug has been used with excellent results, the claim being that it produces little nausea, and later feculent followed by liquid stools, the worm, including the head, being expelled dead. The active principle, kousin, in an impure state has been employed in Germany with varying success. The impure product is apparently more effective than when highly purified. This has led to the belief by some that the green resin present is probably the active principle.

In this country the remedy is probably best given in the form of the fluid extract, made from the fresh flowers, in the dose of ½ fluidounce (16 Cc.), to an adult, and one-half this amount to a child under 12 years of age. The dose of kousin is from 20 to 40 grains (1.3–2.6 Gm.), best administered in divided doses. If the drug fail to purge in 4 hours, it should be followed by a cathartic.

CYDONIUM.—Cydonium.

Semen cydoniæ.—*Quince-seed*, E.; *Quittensamen, Quittenkerne*, G.; *Semences (Pépins) de coing*, Fr.: *Membrillo*, Sp.

The seed of *Cydonia Cydonia* (L.) Lyons (*Pyrus C.* L.; *C. vulgaris* Pers.—Fam. *Rosaceæ*).

Origin.—The well-known quince is a native of western Asia. Each of the 5 cells of the fruit contains about 12 closely packed seeds, found enveloped in a mass of semi-transparent mucilage.

Description.—From 6 to 10 Mm. (¼ to ⅖ In.) long, and a third as broad, ovoid and angularly compressed, the raphe along the sharper edge, the hilum at the narrow end, a slight beak at the other; testa brown, gummy in the epithelium, and having a mass of gum upon the surface.

Fig. 159.

Quince-seed and section.

One part of the seeds with forty parts of water, should yield a thick, jelly-like mass.

Constituents.—"Cydonin," the gum of the epithelium ($C_{12}H_{20}O_{10}$), constitutes about 20 per cent. of the weight of the dry seeds. The cotyledons yield fixed oil.

The pulp of the fruit contains 3 to 3.5 per cent. of malic acid.

Pharmaceutical Preparation.—Mucilage of Cydonium, N. F.

Action and Uses.—Cydonium is rarely employed in medicine, but, like other substances containing a bland mucilage, may be used as a demulcent and protective. Its mucilage is almost free from adhesive properties. The U. S. P. (1880) gave the following formula for its preparation: cydonium, 2 parts (36 grains); distilled water, 100 parts (4 fluidounces); macerate the cydonium for half an hour in a covered vessel, with the distilled water, frequently agitating. Then drain the liquid through muslin without pressure. This preparation should be freshly made for immediate use.

CYPRIPEDIUM, *U. S.*—Cypripedium.

Rhizoma cypripedii.—*Yellow ladies' slipper root, Yellow moccasin-flower, Yellow Indian shoe, Venus' shoe, American valerian, Male nervine, Yellow Noah's ark,* E.; *Gelbfrauenschuhwurzel,* G.; *Racine de cypripède jaune, Valeriáne americáine,* Fr.

The dried rhizome and roots of *Cypripedium hirsutum* Mill. (*C. pubescens* Swartz) or of *C. pārriflorum* Salisb. (Fam. *Orchidaceæ*).

Origin.—Perennial, hairy herbs, a foot or two high, of boggy or low woodlands of the northern and middle United States, and northward. The flowers are bright-yellow and showy, the corolla-lip forming a large, inflated, bag-like body. The hairs are irritant and capable of producing a cutaneous eruption upon many persons.

Description.—Orange-brown to dark-brown; rhizome of horizontal growth, curved, 5 to 10 Cm. (2 to 4 In.) long and 3 to 6 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ In.) thick, the upper surface beset with numerous saucer-shaped or cup-shaped scars which may be slightly elevated or depressed, below covered with numerous unbranched, wavy, coarse roots, which are frequently matted so as nearly to conceal the rhizome; brittle, the fracture short, white; odor heavy, peculiar, or somewhat like valerian; taste sweetish, bitter and aromatic, slightly acrid.

Hydrastis (which see) is frequently found admixed.

Constituents.—These are not very definitely known. Blair (1866) found a minute amount of volatile oil, a volatile acid, 2 resins, tannin, and starch, and these results were confirmed in 1887 by Beshore, who states that the tannic principle is distinct from both tannic and gallic acids.

FIG. 160.

Cypripedium pubescens: portion of rhizome and roots (Nat.).

Pharmaceutical Preparation.—FLUIDEXTRACT OF CYPRIPEDIUM, U. S. P.

Action and Uses.—Cypripedium has been employed for about the same purposes as valerian. It is an antispasmodic, and is supposed to possess a slight stimulant effect upon the nervous system. It has been given with asserted success in hysteria, hypochondriasis, and chorea. It is also stated that it may be employed with benefit in the treatment of epilepsy.

The dose is stated to be 15 grains (1 Gm.), 3 times a day. An oleoresin obtained by precipitating the tincture is employed in doses of from $\frac{1}{2}$ to 3 grains (0.03–0.2 Gm.).

Other Species.—*Cypripedium,* L., comprises about 20 species, of the north-temperate zone, nearly half of them possessing properties similar to those of the official. The leaves of *C. guttatum* Swz., of northern Asia, are used for epilepsy.

D.

DAMIANA.—Damiana.

The leaves of *Turnera diffusa aphrodisiaca* (Ward) Urban (*T. aphrodisiaca* Ward; *T. microphylla* Desv.—Fam. *Turneraceæ*), a small yellow-flowered shrub growing from southwestern Texas through Mexico, especially the western and west-central portions, to northern South America, and in some parts of the West Indies.

Fig. 161.

Damiana (Nat.).

Description.—Owing to the exceeding variability of the plant, and even of the leaves upon the same plant, this drug calls for a very elastic description.

From 1.5 to 3 Cm. ($\frac{3}{5}$ to $1\frac{1}{5}$ In.) long and 3 to 6 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ In.) broad, without a true petiole, oblanceolate to obovate, acute or obtuse at the summit and short-cuneate at the base, serrate-dentate, pale-green, with ascending veins, thick or thin, from nearly smooth with whitish hairs on the veins underneath (this mostly in the older and thicker leaves) to tomentose or flocculent underneath or upon both surfaces; pleasantly fragrant, and of an aromatic and bitterish taste. The slender, reddish stems, 5-merous flowers, with 3-nerved sepals and obovate yellow petals, and globoidal, 1-celled and many-seeded capsules, are often present.

Constituents.—Damiana yields 0.5 per cent. of an amber-colored volatile oil with a heavy, aromatic odor and a warm, camphoraceous, bitter taste, light-brown amorphous bitter *damianin*, which is soluble in ether and chloroform, 6.4 per cent. of hard resin, 3.5 per cent. of tannin, soft resin, sugar, and gum.

Pharmaceutical Preparations.—Elixir of Damiana, N. F.; Fluidextract of Damiana, N. F.

Action and Uses.—Damiana possesses the properties of a stimulant tonic, and in large quantities is laxative. As an aphrodisiac it is probably valueless, and it has no power to restore either the size or function of an atrophied testicle. It has been largely employed in sexual impotence, but as it is usually combined with phosphorus and nux vomica it is quite probable that the benefit obtained is due to the latter remedies. The dose of the fluid extract is 30 minims (2 Cc.).

Substitutes and Allied Plants.—Several other plants have been sold for Damiana, notably the leaves of *Isocoma veneta* (H. B. K.) Greene (*Baccheris v.* H. B. K.; *Bigelovia v.* Gray; *Linosyris Mexicana* Schlecht; *Aplopappus discoidea* DC.—Fam. *Compositæ*), which are nearly 5 Cm. (2 In.) long, oblanceolate, the lower half narrowly cuneate, the upper half with about 3 pairs of very sharp teeth, the apex terminating in a similar tooth, thick, light-green, roughish with resin-like granules and occasional black dots, balsamic in odor and taste.

There are more than 50 species of *Turnera*, all, with one exception, plants of tropical or subtropical America, the leaves of many of them being aromatic. *T. apiifera* Mart., of South America, and *T. ulmifolia* L., and *T. angustifolia* Curt., of the West Indies, are used as carminatives, tonics, and, especially the last named, for their mucilaginous properties.

Peckolt states that in Brazil the freshly expressed juice of *Langsdorffii hypogæa* Mart. (Fam. *Balanophoraceæ*), the *Rosa de Caboclo*, or *Indian rose plant*, is used as an aphrodisiac.

DECOCTA, *U. S.*, *P. G.*—Decoctions.

Decoctions, E.; *Décoctions, Tisanes par décoctions*, Fr.; *Abkochungen*, G.; *Decotti*, It.

When the active principles of vegetable drugs are exhausted by boiling with water, decoctions are obtained. Such preparations are obviously not adapted to drugs the activity of which depends upon principles of a resinous nature which are insoluble in water, nor to such as contain volatile oils or other volatile substances which would be dissipated with the vapor of water, and should be restricted to those drugs the active

constituents of which cannot be extracted by water below 100° C. (212° F.). Formerly, decoctions were usually made by using a large quantity of water and boiling it down to one-half, or even to a less amount. No obvious advantage was gained by this method, and in many instances it proved to be decidedly disadvantageous, owing to the alteration and darkening of the extractive matters, and in some cases to changing the nature of the active principles. The pharmacopœias have very properly, in nearly all cases, reduced the time of boiling to 10 or 15 minutes, the general directions given by the present U. S. P. being as follows: An ordinary decoction, the strength of which is not directed by the physician nor specified by the pharmacopœia, shall be prepared by the following formula: Take of the substance coarsely comminuted, 50 Gm.; water, a sufficient quantity to make 1000 Cc. Put the substance into a suitable vessel provided with a cover, pour upon it 1000 Cc. of cold water, cover it well, and boil for 15 minutes; then let it cool to about 40° C. (104° F.), strain the liquid, and pass through the strainer sufficient cold water to make the product measure 1000 Cc. This represents about 23 grains of drug in each fluidounce.

Caution.—The strength of decoctions of energetic or powerful substances should be specially prescribed by the physician.

By following the directions of the P. G., to keep the mixture of drug and cold water for half an hour in a bath of steam arising from boiling water, the time is practically reduced still more; but the physician is required to state the quantity of such drugs for which a maximum dose is given by the pharmacopœia; other drugs may be used in the proportion of 1 part for 10 parts of decoction.

The use of cold water to begin with, insures the complete exhaustion from the drug of all its soluble principles by the gradually heated water, the albuminous principles being subsequently coagulated as the heat is increased to near the boiling-point. If, on the other hand, the drug be at once immersed in boiling water, the albumin contained in cells would be coagulated, and thus seriously interfere with the extraction of the other principles. In preparing compound decoctions, all the drugs may be added to the cold water, with the exception of those which, like senna, are injured by long-continued heat or which contain aromatic or other volatile principles. Such should be added when the decoction is ready to be removed from the fire or steam-bath, and allowed to digest until it is sufficiently cooled for straining. The material should in all cases be cut or bruised, the degree of fineness depending upon the nature of its tissue. Woody drugs may be reduced to a moderately fine powder; leaves, however, and other drugs consisting mainly of loose parenchyma, are better used in the form of a moderately coarse or very coarse powder.

Unless the liquid is to be considerably boiled down, decoctions are best prepared in a vessel provided with a cover, which may be loosely put on until the boiling is completed, when the vessel should be well closed, particularly if additions have been made at the close of boiling. Porcelain is undoubtedly the best material for vessels used for preparing decoctions, since it is not acted upon by the various vegetable principles; for similar reasons, glass flasks will answer a useful purpose in making small quantities of these preparations. As a rule, it is best to avoid metallic vessels, except when made of block-tin and used in connection with a steam-bath. As many drugs contain tannin, vessels made of iron are not adapted for preparing their decoctions, and the usually imperfect covering of galvanized (or zinc) or tinned sheet-iron renders vessels lined with such material but little better suited for this purpose, and still inferior to properly enamelled iron vessels.

As a rule, decoctions should be allowed to cool to below 50° C. (122° F.) before they are strained; principles which are soluble only in hot water are then mostly precipitated, and removed without, in most cases, weakening the medicinal effects of the preparations. But even with this precaution the strained liquid may become unsightly in appearance through the further deposition, on cooling, of apotheme or matter soluble only in hot water. In such cases the pharmacist should be guided by the directions of the pharmacopœia or by the intentions of the physician, and not sacrifice effect to elegance. With some exceptions, decoctions which were formerly made at the house of the patient have gradually fallen into disuse through the introduction of fluid extracts and similar permanent preparations, by which the medicinal properties may be preserved unaltered for months, or even years, while decoctions cannot be depended upon for more than one or, at the utmost, a few days.

DECOCTUM ALOES COMPOSITUM, *Br.*—Compound Decoction of Aloes.

Tisane (Décoction) d'aloès composée, Fr.; *Zusammengestztes Aloedecoct*, G.

Preparation.—Take of extract of Barbadoes aloes, ½ ounce; myrrh, saffron, potassium carbonate, of each, ¼ ounce; extract of licorice, 2 ounces; compound tincture of cardamoms, 15 fluidounces; distilled water, a sufficiency for 50 fluidounces. Reduce the extract of aloes and myrrh to coarse powder, and put them, together with the potassium carbonate and extract of licorice, into a suitable covered vessel with a pint of distilled water; boil gently for 5 minutes, then add the saffron. Let the vessel with its contents cool, then add the tincture of cardamoms, and, covering, the vessel closely, allow the ingredients to macerate for 2 hours; finally, strain through flannel, pouring as much distilled water over the contents of the strainer as will make the strained product measure 50 fluidounces.—Br.

The preparation of the National Formulary is practically identical with the above, and is made in exactly the same manner, the quantities prescribed being as follows: Extract of aloes, 10 Gm.; myrrh and saffron, of each, 7.5 Gm.; potassium carbonate, 5 Gm.; extract of glycyrrhiza, 35 Gm.; compound tincture of cardamom, 250 Cc.; water, a sufficient quantity to make 1000 Cc.

The alkali carbonate is added for the purpose of aiding the solution of the resinous principles of aloes and myrrh; the tincture of cardamom, saffron, and licorice act as correctives, the latter serving more especially for partially masking the nauseous taste of the aloes. The air should be excluded from the preparation as far as possible.

Uses.—This decoction is antacid, tonic, and purgative. It has been employed when purgation is indicated in atonic amenorrhœa, and is useful in the treatment of acid dyspepsia and habitual constipation. The dose is from ½ to 2 fluidounces (16–60 Cc.).

DECOCTUM GRANATI RADICIS, *Br.*—Decoction of Pomegranate Root.

Decoctum corticis radicis granati. Tisane (Décoction) d'écorce de la racine de grenadier, Fr.; *Granat-Wurzel-Rinden Abkochung*, G.

Preparation.—Take of pomegranate root bark, in No. 10 powder, 4 ounces; distilled water, 24 fluidounces. Boil for 10 minutes and strain, making the strained product up to a pint (Imperial) by pouring distilled water over the contents of the strainer.—Br.

Uses.—The action and uses of decoction of pomegranate root will be found under GRANATI RADIX.

DECOCTUM HÆMATOXYLI, *Br.*—Decoction of Logwood.

Tisane (Décoction) de bois de Campêche, Fr.; *Blauholz-Abkochung*, G.

Preparation.—Take of logwood, in chips, 1 ounce; cinnamon bark, in coarse powder, 70 grains; distilled water, 24 fluidounces. Boil the logwood in the water for 10 minutes in a covered vessel, adding the cinnamon toward the end. Strain the decoction, and pour sufficient distilled water over the contents of the strainer to make the strained product measure a pint (Imperial).—Br.

A long-continued boiling of logwood in chips would probably improve the result of this formula. Porcelain or porcelain-lined vessels only should be used.

Uses.—This preparation may be used for those conditions in which hematoxylon is indicated (see HÆMATOXYLUM). Its bulky dose, from 1 to 2 ounces (30–60 Cc.), renders the decoction less desirable than other preparations of the drug.

DECOCTUM SARSAPARILLÆ COMPOSITUM, *P. G.*—Compound Decoction of Sarsaparilla.

Tisane (Apozème) sudorifique, Décoction de salsepareille composée, Fr.; *Zusammengesetztes Sarsaparilla-Decoct, Sarsaparill-Abkochung*, G.

Preparation.—The P. G. directs that 20 parts of sarsaparilla, cut moderately fine, shall be digested with 520 parts of water at a temperature of 35° to 40° C. (95°–104° F.)

for 24 hours; 1 part each of sugar and alum are then added, and the mixture exposed to the heat of a boiling water-bath for 3 hours, after which 1 part each of bruised anise and bruised fennel, 5 parts of senna, cut moderately fine, and 2 parts of licorice-root, crushed, are added, and the heat continued for 15 minutes longer. After settling, the liquid is decanted and the weight brought up to 500 parts by addition of water.

The U. S. P. no longer recognizes the compound decoction of sarsaparilla. The preparation of 1890 was made by boiling 100 Gm. of sarsaparilla, cut and bruised, and 20 Gm. of rasped guaiacum wood, for ½ hour in a suitable vessel with 1000 Cc. of water, and then adding 20 Gm. of sassafras in No. 20 powder, 20 Gm. of bruised licorice-root, and 10 Gm. of bruised mezereum. After covering the vessel, the contents were allowed to macerate for 2 hours, the mixture strained, and sufficient cold water added through the strainer to make the product measure 1000 Cc.

The second formula was constructed upon that of the French Codex, which directs boiling 3 parts of sarsaparilla and 6 parts of guaiacum wood with 200 parts of water, then adding 1 part of sassafras and 2 parts of licorice root, and macerating for 2 hours. It will be observed that this last is much the weaker preparation, and that mezereon bark is not used in it. The first two are simplified formulæ for the *Lisbon diet-drink*, or *Decoctum lusitanicum*, which was formerly much employed. The latter may also be said of *Zittmann's decoction*, of which a *stronger* and a *milder* one are used together. *Decoctum Zittmanni fortius:* Take of sarsaparilla root, cut, 100 parts; digest in water 2600 parts for 24 hours, and add, enclosed in a linen bag, powdered sugar and alum, each 6 parts, calomel, 4 parts, and cinnabar, 1 part; then heat in a covered vessel placed in a steam-bath for 3 hours, stirring frequently, and near the end of the boiling add anise and fennel, bruised, each 4 parts, senna, cut, 24 parts, and licorice root, cut, 12 parts. Express, strain, set aside for some time, and decant to obtain 2500 parts of clear liquid. 2500 Gm. of this are to be divided into 8 parts. *Decoctum Zittmanni mitius:* Take the residue left from the preceding and 50 parts of sarsaparilla, heat with water 2600 parts for 3 hours in a covered vessel placed in a steam-bath, stirring frequently, and when near the end of boiling add lemon-peel, Chinese cinnamon, cardamom, and licorice root, each cut and bruised, 3 parts. Express and operate as before to obtain 2500 parts.—P. G. 1872.

Uses.—The activity of this remedy depends chiefly upon the mezereum and sarsaparilla. It is employed in the treatment of syphilis, scrofulosis, and chronic rheumatism, and is given in doses of from 3 to 6 fluidounces (90–180 Cc.), 3 times daily.

DEXTRINUM.—Dextrin.

Dextrine, Fr. Cod.; *Dextrin, Stärkegummi*, G.

Dextrin is a member of the group of carbohydrates to which cellulose, starch, inulin, and lichenin belong, and has the same empirical formula as these bodies, namely, $(C_6H_{10}O_5)x$. The name dextrin is applied to any or all of the intermediate substances produced during the transformation of starch into glucose, a prefix being added to indicate the degree of conversion; thus, *amylo*dextrin, the first product after change of the starch into amylogen or soluble starch, which causes a purple color-reaction with iodine; *erythro*dextrin, which gives a red color with iodine; *achroo*dextrin, which is not affected by iodine at all, the brownish-red color of iodine remaining. When diastase, or extract of malt, is used as the converting agent, maltodextrin is produced, which is identical with achroodextrin.

While dextrin was observed by Vauquelin as early as 1811, it was more thoroughly studied by Persoz and Payen in 1833. It is assumed to occur in nature associated with glucose and cane-sugar, but its presence in plants and the blood of animals has as yet not been positively demonstrated.

Dextrin may be obtained from starch by the action of dry heat, by dilute acids and heat, by boiling water, and by action of ferments. By prolonged action of these agents starch is easily converted into dextrose or maltose. Being thus partly digested starch, it is used in the manufacture of infants' foods, the ferments ptyalin, amylopsin, and diastase quickly changing dextrin into sugar. The increased digestibility of toast and crust of bread is due to the presence of dextrin.

Crude dextrin is prepared either by the dry heat or acid method. The first consists in heating grain or potato starch, usually the latter, to a temperature of 230°–260° C. (446°–500° F.) in suitable apparatus provided with mechanical stirrers. According to the care observed, the product consists of a white or yellowish powder of faint flour-like odor and insipid taste. It is more or less soluble in cold water, the solubility depending upon the proportion of unconverted starch present. The acid method consists in mixing 1000 parts of potato starch with a mixture of 2 parts of 58 per cent. nitric acid and 300 parts of water, and drying the resulting mass at a temperature of 110°–120° C. (230°–248° F.) until a starch reaction is no longer obtained with iodine. Dextrin thus made resembles the preceding variety, but is usually lighter in color and has a slight acid reaction.

Purified dextrin, suitable for use in pharmaceutical preparations, may be made by mixing dextrin made by the acid method with 3 times its weight of water and adding about 2 per cent. of precipitated calcium carbonate. After thorough agitation, the mixture is allowed to rest for some time, and is then strained through a woollen strainer. The filtrate is concentrated to about two-thirds its volume and poured into twice its volume of 90 per cent. alcohol, whereby the dextrin, freed from acid, glucose, and other impurities, is precipitated. The latter is washed with 70 per cent. alcohol and finally dried on porcelain plates. The German Pharmacopœia of 1872 directed dextrin for pharmaceutical purposes to be made by acting on potato starch with a cold weak solution of oxalic acid for several days, until iodine causes only a wine-red color when added. The acid liquid is then neutralized by means of calcium carbonate, filtered, and the filtrate evaporated to dryness at a low temperature. The residue yields a yellowish odorless non-hygroscopic powder. If carefully prepared, purified dextrin contains only very small quantities of glucose, from which it can be wholly freed by repeated solution in water and precipitation with alcohol.

Commercial dextrin is an uncrystallizable solid occurring both in powder-form and as white or yellowish masses somewhat resembling gum arabic in appearance. It has a slightly sweetish taste, and is also known as *British gum*, and is used on postage stamps and envelopes.

In pharmacy dextrin has been used in powder-form as a diluent and in the form of a mucilage as an emulsifying agent. White dextrin almost invariably requires heat for solution in water on account of the unconverted starch present, but the yellow variety dissolves readily in twice its weight of cold water, forming a mucilaginous liquid after standing a few hours. Boiling water should not be used for making a solution of the yellow dextrin, so as to avoid the formation of glucose.

Dextrin is insoluble in alcohol and ether. Like glucose, it is capable of reducing Fehling's Solution (alkaline cupric tartrate), but may be distinguished from the same by using Barfoed's Solution (cupric acetate, 1 part; distilled water, 93 parts; glacial acetic acid, 1 part), which is reduced by glucose but not by dextrin. Its solution is precipitated by lime water, but not by neutral or basic lead acetate.

Pharmaceutical Preparation.—Mucilage of Dextrin, N. F.

Action and Uses.—Dextrin is rarely employed in internal medicine. The mucilage of dextrin may be given as a demulcent, but is almost entirely used in the arts as an adhesive agent.

DIASTASUM.—Diastase.

An unorganized ferment, or enzyme, occurring in plants, especially in seeds during germination, and possessing the function of converting their starch into sugars.

Diastase is known only by its effects, since the substance itself has never been isolated. Its physical and chemical nature are therefore unknown. Commercial diastase is a concentrated extract containing the diastase, whatever this may be, in an impure condition, and possessing the diastasic property.

Origin.—It is assumed that diastase exists wherever, in the plant-body, starch has to be converted into assimilable forms for the use of the plant, and it is possibly the same agent which converts related compounds. As to whether the diastase is the same

in all cases, or whether there is a class of diastases, cannot at present be stated. For commercial purposes, ordinary diastase is obtained from malt, *Taka-diastase* from certain species of fungi. The diastase is produced during germination from some other body present in the seed, and its amount, or its activity, rises up to a certain point, then declines, and a great deal of care and experience is required to stop the germinating process at the point of greatest activity. At this point, the commercial article can be obtained to the extent of about 0.2 per cent. It is dissolved out of crushed malt by maceration in cold water, filtering the infusion, and pouring the filtrate into twice its volume of 95 per cent. alcohol. The precipitated diastase is collected on a filter and dried at a temperature not exceeding 50° C. (122° F.). Repeated precipitations tend to purify it, but more or less sugar, albumin, and unknown impurities are always present.

Description.—After drying and grinding, diastase is a nearly white, odorless, and tasteless powder, neutral if fresh, acid if old, insoluble in alcohol, soluble in water, and not precipitated by lime, lead acetate, or baryta. The action of diastase, like that of other ferments, is destroyed by high temperatures. It is also destroyed in a freely acid medium. *Taka-diastase* is obtained from the roots of certain species of *Aspergillus* grown upon sterilized bran. It is one of the substances used in Japan in the production of beer.

Solutions of sodium chloride and calcium chloride in moderately concentrated form are without effect on diastase, but concentrated solutions inhibit its action. Fehling's Solution is not affected by pure diastase. If a small quantity of an aqueous solution of diastase be added to a freshly prepared tincture of guaiac previously mixed with a few drops of hydrogen peroxide solution, an intensely blue color will be immediately produced, in which respect diastase differs from pepsin, invertin, and the ferments present in rennet and saliva.

Diastase is recognized in the French Pharmacopœia, which demands that it shall be capable of converting at least 50 times its weight of potato starch into sugar. According to some authorities (Schmidt, Lintner), diastase of prime quality is capable of converting from 2000 to 100,000 times its weight of starch. Aqueous solutions of diastase are unstable and soon lose their power of conversion.

The following test may be applied to ascertain the value of diastase: 0.1 Gm. of diastase is added to 100 Gm. of starch-paste, prepared from 6 Gm. of potato starch, and the mixture heated on a water-bath for 6 hours at a temperature of 50° C. (122° F.), with occasional stirring. At the end of this time a clear colorless solution should result, capable of reducing 5 times its volume of Fehling's Solution, each Cc. of which represents 0.005 Gm. of glucose. For method of testing the diastasic value of malt extracts, see EXTRACTUM MALTI.

Action and Uses.—Diastase is said by Contaret to be identical with ptyalin, the digestive ferment found in the saliva of various animals. It is employed in medicine for the purpose of converting starch into dextrin and sugar in cases of indigestion of the starchy foods. It is also employed in the treatment of atonic dyspepsia.

Taka-diastase is by far the best preparation to employ, and is given in the dose of from 2 to 5 grains (0.12–0.30 Gm.), either in tablet, capsule, or solution, with or immediately after meals.

DIGITALIS, *U. S.*—Digitalis.

Digitalis folia, Br.; *Folia digitalis*, P. G.—*Foxglove* (*from "Folksglove," meaning "Elves'- glove"*) *leaves, Purple foxglove, Fairy-cap, -fingers, -thimbles*, or *-bells, Ladies' glove, Flop-dock, Cottagers, Throatwort*, E.; *Feuilles de digitale pourprée* (*de grande digitale*), Fr.; *Fingerhutkraut*, G.; *Digitale*, It.; *Dedalera*, Sp.; *Dadaleira, Abeloura, Herva Dedal*, Port.

The dried leaves of *Digitalis purpurea* L. (*D. tomentosa* Link et Hoffm.—Fam. *Scrophulariaceæ*), collected from plants of the second year's growth at the commencement of flowering.

Digitalis is official in all pharmacopœias. Most require that it be used within a year after being collected. Many require that it be collected from wild plants; others, that it be taken when the plant is in bloom. The British requires that the plant be just commencing to bloom.

Origin.—The foxglove plant is a biennial or perennial herb, native of western and central Europe, and cultivated very widely as a garden flower and rather extensively for

medicinal purposes. It is said to have become thoroughly naturalized in Australia and in Oregon, producing in the latter State plants attaining 12 feet in height, 6 feet elsewhere being regarded as unusually large. It prefers sandy and partially shaded slopes. During the first year it develops a rather large, fleshy root, and a rosette of radical leaves, but no stem, the latter, with its flowers and fruit, developing during the second season. The stem is mostly simple, the upper half forming a rather dense, often 1-sided raceme of large, pendulous, irregularly bell-shaped flowers, the corolla purple, dark-spotted on the inside. The stem is leafy, the leaves becoming smaller upward, and finally reduced to mere floral bracts.

Since it is impossible to obtain the full physiological effects of digitalis from the use of any of its constituents, a fully satisfactory chemical assay is impossible. Although the percentage of digitoxin is usually taken as the standard, a great deal must be conceded to clinical trial, the results of which do not always agree with the digitoxin test. There is, therefore, more or less of an element of uncertainty in all conclusions, but those set forth below are probably not far from correct.

Geographical Sources.—Reported experiments to determine the relative value of leaves from different localities should be received with great caution, since the conditions of collection and preservation may not have been equivalent. Benyschek has made very extensive comparisons (as to digitoxin yield) of leaves from nearly all sources, collected and preserved under the same conditions, and finds little difference among them. It is almost universally believed that leaves from wild plants are more active than those from cultivated ones, and the digitoxin yield seems to indicate a slight advantage in this respect, but the belief cannot be regarded as fully confirmed.

Collection and Preparation.—It is generally conceded that leaves of the first year's growth are more or less wanting in activity, and digitoxin assay fully confirms this view. It is generally believed that the leaves should be collected when the plant is in flower or just beginning to flower. This idea has largely grown out of the desire to avoid all possibility of mistake as to the plant, a care which is almost entirely unnecessary. Cæsar and Loretz have found the percentage of digitoxin greatest before flowering, and Benyschek has found it to be inversely proportional to the amount of water in the herbage, which would partially agree with the conclusions of the first-named authors. The same authors found the same percentage of digitoxin in the flowers, with their calyx, as in the leaves, but both the flowers and seeds have a different composition from the leaves, and neither should be included. The admixture of the stems is, of course, wholly unwarranted. The leaves should be dried as soon as possible after collection, and great care should be bestowed upon this work. Drying should be rapid, yet without exposure to the sun or to undue heat, and, of course, protected from all extraneous moisture. Doubtless nothing can be better than the old Dutch method of hanging the plants by the roots in a current of warm air. Benyschek found a great increase in the yield of digitoxin from leaves dried upon the stem, over those which were separated before drying.

Preservation.—There is a general opinion that, no matter how carefully kept, digitalis is nearly or quite worthless after a year from the time of its collection, but the idea appears to have no foundation. Deterioration is due to exposure to moisture and light; and if these be excluded, its properties, or at least its yield of digitoxin, can be long preserved intact. Cæsar and Loretz found that properly pressed into bales, and the latter carefully preserved, there was but a very slight change after a year. Moderately pressed into small cakes and carefully preserved, digitalis keeps very well, and the same is true of the powdered leaves if kept in an air-tight and dark container. Benyschek found digitalis unaltered after two and a half years when kept in hermetically sealed, dark-brown or black bottles. He recommended as the best method, keeping them in tins, over lime—the old Dutch method.

Description.—Abruptly contracted into a usually long, stout, winged petiole; blade 10 to 30 Cm. (4 to 12 In.) long and 5 to 15 Cm. (2 to 6 In.) broad, ovate to oval, obtuse or acutish, crenate or erose-dentate, thin, dull, and rather pale-green or grayish underneath; upper surface wrinkled, sparsely hairy, the venation inconspicuous; lower surface densely and finely hairy, the venation conspicuously reticulated, the midrib and principal veins broad and flat, usually purplish, the latter decurrent into the midrib and the lower continued into the wings of the petiole; odor slight, peculiar; taste very bitter, nauseous.

There is no satisfactory method of distinguishing the leaves of the first from those of the second year's growth, in a description, though experience will usually enable one

to recognize them. Wild-grown leaves are apt to be thinner, grayer or paler, more hairy and more inclined to an acute apex. The powder ranges from a pale to a bright-green, and is distinguished from all adulterants by the hairs and the absence of calcium oxalate crystals. The hairs are mostly 3- to 5-celled, and invariably simple, except that they may end in 2 glandular cells. Some are glandular, but most are not. In some the cells are connected by a very slender or filamentous section. Many of the hairs are very much bent or curly. The heads of the glandular hairs are mostly depressed globular, and of a yellowish or light-brown color. The epidermal cells which are accompanied by stomata are very small and have irregular, jagged outlines.

Considerable has been written concerning the adulteration of digitalis, but as a matter of fact it is rarely seen adulterated, and none of the adulterants resemble it sufficiently to lead to a mistake in the light of our description. The leaves of *D. ambigua* Murr. (*D. ochroleuca* Jacq.) are nearly smooth. Those of mullein are yellowish-white and densely long-tomentose and entire; those of Symphytum are entire and scabrous, as are those of *Conyza squarrosa* Gengi (*Inula s.* Bernh.).

FIG. 162.

Digitalis purpurea L.

Constituents.—Because of the difficulty of separating the components without change, and because much of the study has been upon the active principles of the seeds, which by some are claimed to differ from those of the leaves, the chemistry of digitalis is still unsettled. According to Kiliani (1898), the principles of the seeds are *a-digitoxin, digitalin,* and *digitonin;* those of the leaves (less well known) are *b-digitoxin, digitophyllin,* much *digitalein,* and probably *digitalin.* According to Keller, *digitoxin, digitalin,* and *digitonin,* the last named representing purified *digitalein,* are met with both in the seeds and leaves. *Nativelle's digitalin* has been shown to consist almost wholly of *digitoxin,* accompanied by inert crystalline *digitin.* The commercial German *digitalinum purum* is a mixture, containing probably 50 per cent. of *digitonin* and about 5 or 6 per cent. of true *digitalin.* The *digitalinum verum* of Kiliani, or true digitalin, is a glucoside, capable of splitting up into *digitaligenin* ($C_{22}H_{30}O_3$), *digitalose* ($C_7H_{14}O_5$), and *dextrose* ($C_6H_{12}O_6$). *Digitoxin* is a glucoside crystallizing in pearly scales or white needles, which on boiling with dilute acid in alcoholic solution yields *digitoxigenin* ($C_{22}H_{32}O_4$) and *digitoxose* ($C_6H_{12}O_4$), a sugar. According to Kiliani, the *digitoxin* of the seeds ($C_{34}H_{54}O_{11}$) differs from that of the leaves ($C_{28}H_{46}O_{10}$), and he suggests the names *a-digitoxin* and *b-digitoxin* respectively for the two varieties. *Digitophyllin* ($C_{32}H_{52}O_{10}$) is probably *methyl-digitoxin. Digitalein,* supposed by Schmiedeberg, who obtained it as an amorphous yellowish-white powder, to be an individual principle, is not yet chemically well characterized. Investigations concerning it are still in progress. Keller considers it to be *digitonin* with traces of *digitoxin* and *digitalin.* Its yield is said to be about 1 per cent. By some *digitonin* and *digitin* are considered identical.

The following commercial varieties of the active principles of digitalis are of interest:

Digitalin.—Both French and German digitalin occur on the market. The French Pharmacopœia recognizes an amorphous and a crystalline variety, designated respectively as *digitaline amorphe* and *digitaline cristallisée*, which differ materially from each other. The former is also known as *digitaline chloroformique* or *digitaline-Homolle*, and the latter as *digitaline-Nativelle*. Neither variety represents a pure principle, although, as stated above, French crystalline digitalin consists almost wholly of digitoxin. The French Pharmacopœia directs that the amorphous digitalin is always to be dispensed in prescriptions when the physician fails to specify any particular variety. Amorphous French digitalin is a white (slightly yellowish) powder, having a faint characteristic odor and bitter taste. It is soluble in alcohol and chloroform, but difficultly soluble in water and ether. In contact with hydrochloric acid a green color is produced. Crystallized French digitalin occurs as needle-shaped crystals, of very bitter taste, almost insoluble in water, ether, and absolute alcohol, but readily soluble in 90 per cent. alcohol and chloroform. Its solutions in concentrated hydrochloric and phosphoric acids gradually develop a beautiful emerald-green color.

Two pharmaceutical preparations of digitalin are directed in the French Pharmacopœia (Supplement, 1895): *Granules de digitaline*, each granule containing $\frac{1}{10}$ milligramme of crystalline digitalin, 40 milligrammes of milk-sugar, and 10 milligrammes of acacia, the mass being made with honey; *Poudre de digitaline cristallisée au centieme*, a powder composed of 1 part of crystallized digitalin, 2.5 parts of carmine, and 96.5 parts of milk-sugar.

German digitalin is known on the market as *digitalinum purum pulveratum*. As already stated, it consists chiefly of digitonin, containing but a small proportion of true digitalin, and occurs as a yellowish-white amorphous powder, soluble in water and alcohol, but insoluble in ether and chloroform. Being of variable composition, its medicinal value is questionable. It is, however, the source of true digitalin, the *digitalinum verum* of German manufacture, which was first obtained by Schmiedeberg, and has since been more thoroughly studied by Kiliani.

Digitalinum verum. True Digitalin. $C_{35}H_{56}O_{14}$.—This glucoside occurs as a white amorphous powder or colorless characteristic granules. It melts at 217° C. (422.6° F.), is sparingly soluble in water (1000 parts), more soluble in 50 per cent. alcohol, and readily soluble in alcohol and a mixture of chloroform and alcohol. In chloroform and in ether it is almost insoluble. Its solubility in water is very materially increased by the presence of digitonin. Concentrated hydrochloric acid, as well as sulphuric acid, forms yellow-colored solutions with the glucoside, the color of the sulphuric acid solution changing to rose-red and then to violet-red upon addition of potassium bromide. Sulphuric acid containing a trace of ferric sulphate causes a bluish-red color when mixed with true digitalin, which remains permanent for some days. If digitalin be treated with Keller's reagent (see Digitoxin), a bright carmine-red zone is obtained. According to Kiliani, a few grains of true digitalin added to 2 Cc. of 10 per cent. potassium hydroxide solution should not assume a yellow color within 1 minute. The presence of even small quantities of digitonin may be detected by mixing digitalin with sufficient water to form a thin paste and then adding, while shaking, one-fifth as much amyl alcohol as water was used, and setting the mixture aside in a closed flask for 24 hours, when the appearance of wart-like crystals will indicate digitonin.

True digitalin is obtained from the commercial German digitalin by dissolving the latter in 4 parts of 95 per cent. alcohol with the aid of a gentle heat, adding 5 parts of ether (specific gravity 0.720) and setting the mixture aside for 24 hours in a tightly closed vessel to prevent evaporation. The ether-alcohol solution is decanted, evaporated at a low temperature to 1.6 times its content of soluble matter (previously determined in a separate portion), the residue mixed with 1½ times its weight of water, set aside for 24 hours, and the resulting deposit of crude digitalin collected, washed with 10 per cent. alcohol and then with water, and dried on porous tiles or in a vacuum apparatus. It is then purified by solution in 95 per cent. alcohol, treated with animal charcoal, and the solution filtered and slowly evaporated.

Digitoxin. $C_{34}H_{54}O_{11}$.—This valuable glucoside is insoluble in water, almost insoluble in ether, far more soluble in hot than in cold alcohol, but readily soluble in chloroform. It occurs as a white odorless crystalline powder, having a bitter taste, or in form of small

needle-shaped crystals. If crystallized from a solution in methyl alcohol and chloroform, it is anhydrous, but if crystallized from alcohol it contains 5 molecules of water. The former melts at 240° C. (464° F.), the latter at 145° C. (293° F.). Its solution is precipitated only in part by tannin. Concentrated hydrochloric acid forms a deep-green colored solution with digitoxin. Keller gives the following reaction as characteristic for this glucoside: If 0.001 Gm. of digitoxin be dissolved in 5 Cc. of glacial acetic acid, a drop of dilute ferric chloride solution then added, and an equal volume of concentrated sulphuric acid carefully introduced by means of a pipette so that the acid liquids do not mix, a brownish-green zone will appear at the line of contact, rapidly changing to bluish-green and finally to indigo-blue. The upper layer of the sulphuric acid assumes a brownish-red color and the acetic acid is gradually colored green.

Digitoxin has been found in digitalis leaves to the extent of 0.15 to 0.30 per cent., the seeds yielding much less. It is said to be most abundant in the leaves during August, hot dry weather increasing and persistent rain decreasing the yield.

Digitonin. $C_{54}H_{92}O_{28}$ (Kiliani).—This principle, although not possessing any specific medicinal value as far as known at present, is of interest because its association with true digitalin renders the latter more soluble in water, and hence seems to play an important part in aqueous preparations of digitalis. It was found at one time on the market under the name *digitalinum crystallisatum*, and may be extracted from commercial German digitalin by treatment with 4 parts of 85 per cent. alcohol, from which solution it readily crystallizes out. Digitonin is difficultly soluble in water, but more readily in the presence of digitalin, the solutions frothing considerably when shaken. It is readily soluble in 50 per cent. alcohol, amyl alcohol, and a mixture of alcohol and chloroform. It is sparingly soluble in chloroform and insoluble in ether, benzene, and petroleum-ether. When heated with diluted acids, digitonin is split up into digitogenin, galactose, and dextrose. It dissolves without color in hydrochloric acid, but if boiled for some time with the strong acid or with moderately dilute sulphuric acid a fine garnet-red color is observed. It is said by Kiliani to be the cause of gelatinization of fluid preparations of digitalis.

Besides the active principles, digitalis contains volatile oil, 5 per cent. of fixed oil, starch, sugar, gum, inosit, pectin (most in petioles and first-year leaves), red coloring-matter, yellow coloring-matter allied to chrysophan (Schmiedeberg), *digitalosmin*, a stearopten with nauseous, acrid taste and the odor of digitalis, *antirrhinic acid*, volatile and resembling valerianic acid, and *digitalic acid* (malic acid, *Flückiger*), crystallizing in white needles. The fresh and recently dried leaves contain an oxydase ferment.

Pharmaceutical Preparations.—Ethereal Tincture of Digitalis, N. F.; Extract of Digitalis, U. S. P.; Fluidextract of Digitalis, U. S. P.; Infusion of Digitalis, U. S. P.; Tincture of Digitalis, U. S. P.

Valuation of Digitalis.—Owing to the fact that digitalis contains several important constituents, chiefly glucosides, to which its value as a remedial agent is due, and that up to the present time no one of these, when isolated, has been found capable of replacing a corresponding weight of the drug in its own particular action, a chemical method of valuation does not appear very useful, and more reliance should be placed upon carefully conducted physiological tests with the drug itself. Nevertheless, since digitoxin is now known to be the chief heart-stimulating principle of digitalis, a determination of its content in the drug must prove of interest. Keller has suggested the following method: Well-dried digitalis leaves in No. 60 powder are used, and of these 20 Gm. are moistened with 8 Cc. of 70 per cent. alcohol, firmly packed into a cylindrical percolator, and slowly exhausted with the same menstruum. About 300 or 350 Cc. of percolate may be required, which is evaporated with constant stirring, on a water-bath, to 25 Gm., so as to get rid of all alcohol. The residue is mixed with water and washed into a flask of 250 Cc. capacity, sufficient water being added to bring the total weight up to 222 Gm., to which 25 Gm. of solution of lead subacetate are then added and mixed by gentle rotation of the flask. The mixture is poured into a rapidly acting filter of 7 inches diameter, and 132 Gm. of the clear pale-yellow filtrate transferred to an Erlenmeyer flask, a solution of 5 Gm. of crystallized sodium sulphate in 7 Gm. of water being added to remove excess of lead. In order to avoid troublesome filtration, the flask is placed in a slanting position for 4 or 5 hours and 130 Gm. of the clear liquid then carefully decanted and transferred to a separator. After addition of 2 Cc. of 10 per cent. ammonia water the contents are shaken out with 4 or 5 successive portions, of 30 Cc. each, of chloroform. The chloroformic solutions are passed through a double 4 inch filter, previously wetted with chloroform, into a tared Erlenmeyer flask and distilled on a water-bath. Crude digitoxin will remain as a yellow varnish-like residue, which may be purified by redissolving in 3 Gm. of chloroform and then adding 7 Gm. of ether and 50 Gm. of petroleum-ether (benzin). By active shaking

the liquid becomes clear, and the dixitoxin settles on the bottom of the flask in the form of a white flocculent deposit, which is collected on a small filter and the flask and filter washed with a little petroleum-ether. After the filter has drained, the funnel is placed in the flask and the moist precipitate dissolved by means of hot absolute alcohol. The alcoholic solution is evaporated on a water-bath, 5 Cc. of ether added to the residue and also evaporated, when the digitoxin will be obtained partly amorphous and partly in crystalline form, and can be weighed. The weight of digitoxin multiplied by 10 will express the percentage present in the drug. It is not claimed that the digitoxin obtained by the above process is absolutely pure, and it may be contaminated with traces of digitalin.

Fromme has modified Keller's method by macerating 28 Gm. of the drug with 280 Gm. of the menstruum for 3 hours, shaking frequently, and, after filtration, using 207 Gm. of the liquid for evaporation to 25 Gm. From this point the two methods are alike.

Action and Uses.—When digitalis is taken in overdose, it is apt to produce nausea and vomiting. Aside from these manifestations of gastric disorder, the symptoms which follow are connected almost entirely with the circulatory system, and consist in faintness and collapse. Under the influence of excessive doses the pulse becomes at first full, slow, and strong; but as the truly poisonous effects of the drug are manifested, it varies greatly in its character, sometimes being rapid and hobbling, and at others very slow, so that within the space of a minute the pulse may be as low as 40 or 50, and again as high as 120. Any change in the posture of the patient during this time causes very great irregularity in the action of the heart, and sudden death may occur. When the drug is taken in medicinal doses, it increases the force and fulness of the pulse and raises arterial pressure. The increase in pulse force is due to the stimulating effect of the drug on the heart muscle. The increase in the volume of the pulse is due to the wide diastole of the heart, which is produced by the influence of the drug upon the vagi centrically and peripherally; and the rise in arterial pressure is caused first by the increased action of the heart, and second by the stimulant effect exercised by the drug upon the vasomotor centre in the medulla oblongata and upon the muscular coat of the bloodvessels. While the drug slows the pulse, it nevertheless, because of its diastolic and stimulant effect upon the heart, causes a larger quantity of blood to be expelled from this viscus in a given space of time than is expelled under ordinary circumstances, and this is the reason that digitalis is so valuable in patients suffering from deficient and poor circulation.

As has been pointed out in this article, the drug is composed of a number of active ingredients, all of which produce definite effects, but none of which can be used for the purpose of producing an effect identical with that of digitalis itself. The digitalin of Schmiedeberg, digitoxin, and digitalein, all act as powerful stimulants to the heart muscle; digitalin also stimulates the vagus peripherally and centrically; and all of them raise arterial pressure by stimulating the vasomotor system centrically and peripherally. Another active principle, namely, digitonin, does not, however, stimulate the heart muscle, but is rather depressant in its influence on this organ. It also depresses the pneumogastric nerve, and thereby somewhat antagonizes the effect of the other active principles. It is evident, therefore, that when the physician desires to get the full effect of digitalis, he should employ the drug itself rather than one of the active principles that have been named; although if he simply wishes to get increased cardiac power, he may employ the digitalin of Schmiedeberg if he so desires. There does not seem, however, to be any definite view as to the exact strength of this product, some physicians using it in so small doses as $\frac{1}{100}$ of a grain (0.0005 Gm.), while others have given as much as $\frac{1}{4}$ of a grain (0.015 Gm.), or even 1 grain (0.06 Gm.) of it at each dose with asserted advantage.

The slow, full pulse produced by preparations of digitalis are the result of its stimulant effect upon the pneumogastric nerve both centrically and peripherally.

Digitalis increases urinary flow by increasing the supply of blood to the kidney and by increasing the blood-pressure in that organ. It does not, however, cause any true stimulation of the secreting epithelium of the kidney, and therefore does not materially increase the quantity of solids which are eliminated in the urine.

Digitalis is employed in medicine as a cardiac stimulant in conditions in which the heart seems to be failing as the result of exhaustion produced by some prolonged malady, but it is also employed even more commonly for the relief of heart feebleness occurring as the result of valvular disease, whereby the heart muscle becomes feeble and inactive. It is in the treatment of ruptured compensation, as it is called, resulting from valvular disease, that digitalis finds its chief usefulness in medicine, since in those

instances in which the heart is feeble as a result of degeneration of the heart muscle it is not possible for it to produce good results for obvious reasons.

Digitalis may be employed with advantage in all forms of valvular disease of the heart provided the heart muscle is tired and failing. It is least advantageous in cases of aortic regurgitation, since in this malady the prolongation of diastole produced by the drug sometimes increases the quantity of blood which regurgitates from the aorta into the left ventricle. It is in cases of cardiac failure that digitalis acts most efficiently as a diuretic, under these circumstances often removing fully developed dropsy with extraordinary speed and producing its good effect primarily by the improvement in the circulation, and, secondarily, by the improvement in the blood-supply of the kidney, which is, therefore, enabled to pass from the body large quantities of liquid.

Digitalis was at one time largely used as a heart stimulant in the course of infectious diseases, but is less employed at the present time than formerly, because we now recognize that the cardiac failure of these states is often dependent upon degeneration of the heart muscle, and also because digitalis, on further study, has not proved to be always reliable in these conditions. Of all the infectious diseases in which it is employed most commonly and with the best result, croupous pneumonia stands first. The drug is also of value to support the heart in cases of emphysema and asthma. Its use is contra-indicated in those persons who have marked atheromatous or degenerative changes in their bloodvessels.

In cases of aneurism, and in cases of feeble heart dependent upon high arterial pressure, its use is dangerous unless simultaneously with the administration of the digitalis nitroglycerin is given to reduce arterial tension.

The administration of full doses of digitalis causes marked gastric irritability, and even vomiting. This can usually be avoided by the employment of small doses more frequently repeated, and we think that, as a rule, better results can be obtained by small doses given over a considerable period of time than by large doses, which speedily produce effects which necessitate the abrupt stopping of the use of the drug.

As the effects of digitalis are prolonged, it may, when given in full dose for a long time, produce cumulative effects or symptoms of mild poisoning. It is best to stop its use every eighth day for the space of forty-eight hours.

The dose of powdered digitalis leaves is from $\frac{1}{8}$ to 1 grain (0.008–0.06 Gm.); of the fluidextract, 1 to 5 minims (0.05–0.3 Cc.); of the tincture, 5 to 20 minims (0.3–1.3 Cc.); of the infusion, 1 teaspoonful to 1 ounce (4–30 Cc.). There can be little doubt that the most diuretic of the preparations of digitalis is the infusion, probably because it contains less digitalin than the other preparations, for digitalin sometimes causes spasm of the renal bloodvessels, and so temporarily diminishes urinary flow. On the other hand, the infusion is a much more disagreeable preparation to take, and is far more apt to disorder the stomach than are the digitalis leaves themselves, the fluid extract, or the tincture.

The proper beginning dose of digitalin, unless it is known that the patient can take large doses of it with impunity, is $\frac{1}{100}$ of a grain (0.0008 Gm.). In the employment of digitalis, it is important that the physician shall prescribe preparations which have been made from drugs physiologically tested, since digitalis leaves vary very greatly in their physiological effects. (See *Physiological Testing.*)

Allied Species.—The genus *Digitalis* L. is credited with 22 species. A number of these have been investigated by H. Goldenberg, who believes that all the species have similar properties, though differing greatly in activity. *D. eriostachys* Bess., *D. glandulosa*, and especially *D. Fontanesii* Steud., are only slightly active; while *D. nervosa* Steud. is 1½ times and *D. ferruginea* L. 10 times, as active as *D. purpurea*. He finds the stem to contain a different physiological agent ("digital-resin") from the leaves, which at first excites the nerve-centers and finally paralyzes the muscles.

DIOSCOREA.—Wild Yam; True Wild Yam; Colic Root; Rheumatism Root.

The rhizome of *Dioscorea villosa* L. (Fam. *Dioscoreaceæ*), a very slender, dicœcious, twining climber of the eastern and central United States, having broadly ovate, cordate, acute, ribbed leaves, minute greenish flowers in small and slender drooping axillary panicles, and triangular winged capsules about ½ inch long and broad.

Description.—In crooked pieces, mostly from 15 to 50 Cm. (6 In. to nearly 2 Ft.) long, and 6 Mm. to 1 Cm. (¼ to nearly ½ In.) thick, mostly unbranched, slightly flattened

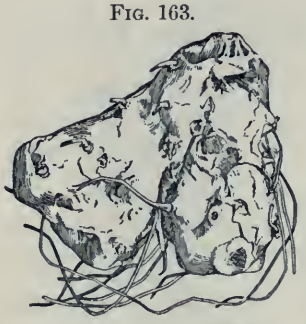
from above downward, bearing upon the upper surface small, nearly circular stem-scars, upon the sides small nodular protuberances, and underneath fine, slender, wiry roots; externally brown, sometimes with the bark exfoliating; internally whitish, very starchy, and with numerous yellowish-white, fine, fibrovascular bundles; inodorous and at first tasteless, afterward somewhat acrid.

Constituents.—These have not been properly investigated. The acridity is due partly to resin, partly to a saponin-like substance, and the medicinal effects are doubtless to be ascribed to the same agents. Starch is present in large quantity.

Action and Uses.—Dioscorea has never been largely employed in medicine, but it is said to possess expectorant, diaphoretic, and in large doses emetic properties. Some practitioners have recommended it as a remedy in the treatment of bilious colic, and the laity occasionally employ it in the treatment of muscular rheumatism. It may be given in doses of from 10 to 40 minims (0.6–2.6 Cc,) of a fluidextract, 3 times daily; or a decoction, made by boiling 1 ounce (30 Gm.) of the rhizome with 1 pint (480 Cc.) of water, may be taken in doses of from 4 to 6 fluidounces (120–180 Cc.). The resinous substance, improperly called "dioscorein," made by precipitating an alcoholic tincture with water, is given in doses of from 1 to 4 grains (0.06–0.25 Gm.).

False wild yam (the rhizome of *D. villosa glabra*) is more abundant southward, where the other gradually disappears. This rhizome sometimes reaches 15 Cm. (6 In.) long, and 2 to 4 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) thick, flattened from above, crooked, with short branches almost as thick as itself alternating upon the two sides, above bearing crowded, large, depressed circular stem-scars and underneath numerous smooth wiry simple roots; externally whitish to pale yellowish-brown; fracture tough, exhibiting a compact whitish starchy tissue with numerous scattered yellowish wood-bundles; inodorous, at first tasteless but becoming strongly acrid. Its constituents are similar to those of the last, but there are more of the acrid principles, and the drug is probably more active.

Fig. 163.



Dioscorea villosa glabra (¾ Nat.).

Other Species.—About 150 species are known, mostly tropical, in both hemispheres. A number of species yield the valuable yams, while others contain poisonous principles. Of the former, the following are the most important: *D. alata*, L., *White negro yam; D. triphylla* L., *Buck yam; D. pentaphylla* L. (*D. trifida* L.), *Indian yam;* and *D. sativa* L., *Common yam.* The smaller cylindrical tuberous rhizomes of *D. Japonica* Thunb. and *D. quinqueloba* Thunb. are eaten in Japan. The former is about 10 Cm. (4 In.) long, farinaceous, and white; the latter is smaller, externally pale-brown, internally dingy-white, and has a bitterish taste. As nutrients, the yams are almost wholly farinaceous. *D. hirsuta* Blume, though actively poisonous, is used as food in Java after the thin slices have been exposed for 24 hours to the action of running water.. It contains the alkaloid *dioscorine* ($C_{13}H_{19}NO_2$), which occurs in yellowish-green crystals, and is very hygroscopic, and slightly volatile. It acts upon animals somewhat like picrotoxin, but is less active. *D. bulbifera* L. yields a glucoside, and is used in Brazil as an antidysenteric and antisyphilitic, sometimes to poison vermin. A large number of species have been reported as either poisonous or edible, but the extreme difficulty of classifying and identifying them casts grave doubt upon the determination of the species, in most cases.

Dioscoriaceæ (*the Yam Family*).—Genera, 9; species, not more than 20 apart from the large genus *Dioscorea*, just considered. The rhizomes and tubers of several are eaten like yams, or yield starch. The rhizome and seeds of *Tamus communis* L. (*Black bryony, Black bindweed, Adders' meat, Murrain-berries,* or *Ox-berries, Schmeerwurz* (G.), chiefly of the Mediterranean region, are diuretic, emetico-cathartic, and poisonous, although the young shoots, thoroughly cooked, are eaten like asparagus. The root-stock of *T. edulis* Lowe, of the Madeira Islands, is eaten.

DIOSPYROS.—Persimmon.

Winter-, Seeded- or Date-plum, Possum wood, North American ebony, E.; *Persimmonfrüchte, Dattelpflaumen,* G.; *Fruits de plaqueminier de Virginie,* Fr.

The unripe fruit of *Diospyros Virginiana* L. (Fam. *Ebenaceæ*).

Origin.—From a good-sized tree growing in the eastern and east-central United States, from Rhode Island southward. The fruit ripens in November, but should be collected for medicinal purposes in October, while yet green and rich in tannin.

Description.—A globular berry about 2.5 Cm. (1 In.) in diameter, borne upon a short

pedicel and with a persistent basal, 4-lobed, leathery calyx, tipped with a short style-remnant, smooth, green, tough, 4- to 6-celled with a single flattened, ovoid-oblong seed in each cell; fleshy and juicy, the juice viscid and highly astringent. After being ripened by the frost, it becomes of a rich reddish-brown, much wrinkled, soft, sweet, and edible.

Constituents.—The unripe fruit contains, besides much tannin, pectin, malic acid, and sugar.

Action and Uses.—Both the bark and the unripe fruit of the persimmon tree are tonic and astringent. An infusion of the bark (1 ounce to the pint; 30 Gm.–480 Cc.) has been employed as an antiperiodic and as a gargle in sore throat. An infusion made from the green fruit has also been recommended in the treatment of diarrhœa, dysentery, leucorrhœa, and uterine hemorrhage. The infusion made from the fruit (1 ounce to 2 fluidounces—30 Gm.–60 Cc.—of boiling water may be given in 30-minim (2 Cc.) doses to an infant, and in doses of from ½ to 1 fluidounce (16–30 Cc.) to an adult.

Other Species and Allied Products.—The bark of the tree is also rich in tannin, and contains a non-nitrogenous crystalline principle.

The genus contains almost 200 species, mostly tropical, in both hemispheres. They possess generally the astringent properties of the above, and are so used. The ripe fruits of many are edible, several of them being important products of cultivation. That of *D. decandra* Lour., of Cochin China, has peppery qualities. *D. maritima* Blume, of the East Indies, yields a blue dyestuff. *D. melanoxylon* Roxb., of India, yields a gum. *D. Ebenaster* Retz., of the East Indies, is used as a fish poison. *D. Ebenum* Kon. is the source of ebony.

Several other of the 250 species of the family *Ebenaceæ* (*Cavanillea* and *Euclea*) yield edible fruits, and others (*Maba*) yield similar astringent barks.

DIPTERYX.—Tonka.

Semen or Faba tonca.—Tonka ("*Tonquin*") *bean, Coumarouna bean, Snuff bean*, E.; *Tonkabohnen*, G.; *Tonka*, Fr.; *Hava Tonka*, Sp.

The prepared ripe seeds of several species of *Coumarouna* Aubl. (*Dipteryx* Schreb. —Fam. *Leguminosæ*).

Origin.—There are about 8 species of this genus of tropical American trees, some of them of great size and very beautiful, bearing a general resemblance to the licorices. But two species are usually named as yielding tonka, namely, *C. odorata* Aubl. (*Dipteryx o.* Willd.), chiefly of the northern part of the Amazon valley, and yielding the *Dutch tonka*, and *C. oppositifolia* (Aubl.) Taubert (*Turalea o.* Aubl.; *Dipteryx o.* W.), growing chiefly in the Orinoco valley, and yielding *English tonka*. It seems very likely that the commercial article is derived in part from other species. It has, in fact, been stated that the seeds of *C. pteropus* (*Dipteryx p.* Mart.), the *Cambaru seeeds*, and of *C. oleifera* (Benth.) Kuntze (*Dipteryx o.* Benth.), the *Eboes nuts*, are sold as tonka. Tonka trees are somewhat cultivated, but the industry can scarcely be said as yet to have passed the experimental stage. Plantations which we saw in Venezuela developed with great slowness, the trees appearing to lack some essential natural condition. The 1-seeded legume is oval, resembling a mango in appearance, and not very unlike a peach. The mesocarp consists of a tough, stringy flesh, which, when ripe, is sweetish and somewhat edible. The fruit is tardily dehiscent, and is broken open for the collection of the seeds. These, like vanilla, have at first none of the fragrance for which they are valued, the fragrant principle being developed by a process of curing. The usual native custom is to steep the seeds in rum or other native-made spirit for several days, the cumarin being thus developed, quantities of it being also recovered in a crude and impure condition from the liquor, which is used for successive lots of seeds.

Description.—Tonka beans are from 2.5 to 5 Cm. (1 to 2 In.) long, a half or less as broad, oblong-ovoid, somewhat flattened, one edge sharp and one end somewhat pointed, elsewhere rounded, either black and fatty-lustrous, or grayish-black and more or less covered by an efflorescence of cumarin, the leathery testa heavily wrinkled; kernel consisting of 2 brownish fleshy cotyledons, their flat faces usually a little separated except at the edges, the cavity frequently containing large crystals of cumarin; odor strongly vanilla-like, taste sweetish, aromatic, bean-like. The Dutch variety is usually the larger, and more often gray. Angustura tonka is long, slender, black, and shining. Para tonka is similar to the Augustura, but shorter and smaller.

Constituents.—The only important constituent is CUMARIN, which is present to the extent of 1.5 to 2 per cent. The uses are purely dependent upon the properties of this substance

Cumarinum. Cumarin, Cumaric anhydride, Ortho-oxycinnamic anhydride, E.; *Cumarin, Tonkabohnenkampfer*, G. $C_9H_6O_2$ or $C_6H_4\begin{cases}CH:CH\\ |\\ O—CO\end{cases}$.—Cumarin may be readily extracted from coarsely powdered tonka beans by means of boiling 80 per cent. alcohol. The resulting solution is concentrated and the residue mixed with 4 times its volume of boiling water. After filtration through a well-wetted filter, for the removal of fat, the liquid is set aside, when the cumarin will crystallize out, and may be purified by redissolving in hot water, decolorizing with animal charcoal, and again crystallizing.

By far the bulk of cumarin offered on the market is produced synthetically, the following method being generally employed: A mixture of 3 parts of salicylic anhydride, 5 parts of acetic anhydride, and 4 parts of anhydrous sodium acetate, is gently boiled for several hours in a flask provided with a reflux condenser. Upon cooling, the mixture congeals to a crystalline mass, which after addition of water separates an oily liquid consisting of a mixture of acetyl-orthocumaric acid and cumarin. By distillation the acid is split up into acetic acid and cumarin, which latter is then dissolved in hot water and crystallized.

Cumarin occurs in colorless prismatic crystals having a characteristic fragrant odor and bitter, aromatic taste. It melts at 67° C. (152.6° F.), sublimes at 100° C. (212° F.), and boils at 291° C. (555.8° F.) without decomposition. Cumarin is soluble in 400 parts of cold or 45 parts of boiling water, and is readily soluble in alcohol and ether. It is also soluble in chloroform and in fixed and volatile oils. Acetanilid has been found as an adulterant in cumarin, and may be detected by boiling 0.1 Gm. of the suspected article for a few minutes with 1 Cc. of 25 per cent. hydrochloric acid and adding to the clear solution 2 Cc. of a 5 per cent. carbolic acid solution and a small quantity of fresh chlorinated lime solution. The presence of acetanilid would cause a red color to appear, which changes to indigo-blue upon supersaturation with ammonia water.

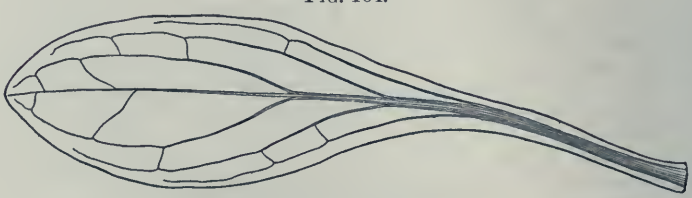
Action and Uses.—Cumarin, the active principle of tonka, is said to be an antispasmodic and narcotic. In full dose it primarily stimulates the circulation, but later acts as a cardiac depressant. A fluid extract of tonka has been given in the treatment of pertussis, in doses of from 5 to 10 minims (0.3–0.6 Cc.). It may also be tried as a remedy for flatulent colic and diarrhœa.

In pharmacy cumarin is sometimes used to disguise the odor of iodoform. It is chiefly employed in perfumery, and has been used in the manufacture of cheap extract of vanilla, which adulteration can be detected by the method given under VANILLA (which see).

Other Sources of Cumarin.—Cumarin is a widely distributed substance in the vegetable kingdom. One of the important sources is Melilotus (see LEGUMINOSÆ). It is also yielded by the seed of *Copaiba Salicounda* Heck., of western Africa, in which the content, chiefly in the embryo, is about 0.75 per cent., and associated with about 4 per cent. of fixed oil. All parts of the tree, except the leaves, are said to possess the cumarin odor. The natives use the seeds as a mild antispasmodic, as well as for perfumery.

In the southeastern United States large quantities of the leaves of *Trilisa odoratissima* (Walt.) Cass. (*Anonymos o.* Walt.; *Liatris o.* Mx.—Fam. *Compositæ*), the *Vanilla plant, Carolina vanilla, Deer's-tongue*, or *Dog's-tongue*, are collected for the cumarin which they contain. The plant is a stout perennial, sometimes nearly a yard in height, the alternate leaves gradually becoming smaller and narrower from the base upward, the handsome purple heads in a corymbose panicle, each about 6 Mm. (¼ In.) high. The radical leaves, which are chiefly collected, are 10 to 25 Cm. (4 to 10 In.) long, and of the form shown in the accompanying illustration, thickish and somewhat fleshy, smooth, and of a strong cumarin odor when dried. Considerable amounts of cumarin are also present in several grasses, and in *Asperula*.

FIG. 164.



Trilisa leaf (½ Nat.).

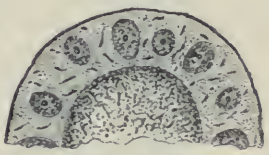
DRACONTIUM.—Dracontium.

Skunk-, Swamp-, or *Meadow-cabbage, Skunk-weed, Pole-cat weed, Collard, Stinking-poke or Hellebore,* E.; *Pothos fetide,* Fr.; *Stinkende Drachenwurz,* G.

The dried rhizome and roots of *Spathyema fœtida* (L.) Raf. (*Dracontium f.* L.; *Ictodes f.* Bigel.; *Symplocarpus f.* Nutt.; *Pothos f.* Mx.—Fam. *Araceæ*).

Origin.—The plant occurs in great abundance in rich swamps of eastern and central North America, and is curious, interesting, and ornamental. The ovoid, pointed, purple or richly purple spotted, smooth and shining spathes, a few inches in length, and half or more as broad, with incurved tips, and of thick and crisp texture, protrude from the soil in earliest spring, and soon contain numerous yellow flowers densely massed upon a globular spadix. Soon after, the leaves appear in a dense, subradical, cabbage-like but loose cluster. They are very large, ovate-cordate, almost or quite as broad as long, thick, smooth, and shining, more or less netted-veined, entire-margined and short-stalked. The entire plant exhales a very strong mephitic odor when bruised.

FIG. 165.



Dracontium fœtidum: section through one-half of upper part of rhizome (Nat.).

Description.—The rhizome is 7 to 15 Cm. (3 to 6 In.) long, 5 Cm. (2 In.) thick, oblong-cylindrical, truncate at both ends and densely beset on all sides with long, coarse, simple, exceedingly strong roots. When dried, both are at first yellowish-white, but may become very dark gray-brown or blackish and strongly wrinkled. The rhizome is hard and heavy. Internally it is white and starchy. Upon being rubbed, it exhales its characteristic odor, but both this and the acrid and biting taste gradually disappear with long keeping. It frequently occurs in market, deprived of its roots and cut into transverse slices.

Constituents.—These are very imperfectly known. J. M. Turner (1836) obtained from it a volatile fatty matter, a little volatile oil, resin, wax, fixed oil, sugar, gum, and starch. The active constituent appears to be the volatile principle, which is dissipated by heating and disappears upon keeping. The seeds apparently contain it in larger amount and are similarly used.

Action and Uses.—Dracontium is asserted to possess the properties of a stimulant, sialagogue, emetic, antispasmodic, and narcotic, but it is rarely employed in medicine. When given internally, it occasions nausea and vomiting, frontal headache, and vertigo. It has been employed as a remedy in the treatment of chorea, hysteria, spasmodic asthma, chronic bronchitis, and rheumatism, but is probably of little value in any of these conditions. The dose of the recently dried drug is from 10 to 20 grains (0.65–1.3 Gm.). As it rapidly deteriorates, the remedy as found in the stores is of variable strength. An infusion made with 1 ounce (30 Gm.) of the drug in 1 pint (480 Cc.) of boiling water is given in doses of from 1 to 8 fluidrachms (4–30 Cc.). An alcoholic tincture of the same strength may be used in 1- to 2-drachm (4–8 Cc.) doses.

DROSERA.—Sundew.

Herba rorellæ, H. roris solis, H. droseræ.—Round-leaved or Common sundew, Youthwort, Moorgrass, Red-rot, Rosa-solis, E.; *Sonnenthau, Sinnthau, Jungfernblüthe,* G.; *Rosolis, Rosée du soleil,* Fr.

The entire plant, *Drosera rotundifolia* L. (Fam. *Droseraceæ*).

Origin.—A diminutive moss-like plant, abounding throughout most of the north-temperate zone, especially in North America, its common name depending upon its strikingly beautiful appearance when covered with dew and glittering in the sunshine.

Description.—Leaves in a radical rosette, the blade 5 to 10 Mm. ($\frac{1}{5}$ to $\frac{2}{5}$ In.) long and equally broad or broader; abruptly narrowed into a broad petiole, rounded at the summit, entire, fleshy, beset with long, stiff, glandular hairs, those of the margin purplish-red; scape 10 to 20 Cm. (4 to 8 In.) long, smooth, slender, bearing a terminal raceme of white flowers about 4 Mm. ($\frac{1}{8}$ In.) broad, the calyx-lobes, petals, and stamens each 5, the ovary 1-celled, the styles 3, the capsule 3-valved and many seeded.

Constituents.—This plant yields a greenish-brown, odorous, very acrid resin, glucose, citric and probably malic acid, and a ferment which converts albumin into peptone. It contains no formic or butyric acid.

Action and Uses.—Sundew has been recommended in the treatment of chronic bronchitis, whooping-cough, and tuberculosis, but probably has no medicinal value in these conditions. The dose is stated to be 5 minims (0.3 Cc.) of a 10 per cent. tincture.

Fig. 166.

Drosera rotundifolia (Nat.).

Allied Species.—The family is of great interest because of the carnivorous habits of its plants, and the proteolytic enzymes which perform this work have been objects of curious interest. It is not unlikely that they may act usefully in the human system. The genus *Drosera* L. contains more than a hundred species, a dozen or more of which are similarly employed. Those which have been examined contain one or more acrid fixed oils or soft oleoresins. *D. filiformis* Raf., of North America, has erect, filiform, densely glandular hairy leaves, often a foot or more long and similar scapes bearing pretty purple flowers, 2 to 4 times as large.

Dionœa muscipula L., the celebrated *Venus' fly-trap* of the southeastern United States, is similarly employed.

Related Families.—Closely related to the *Droseraceæ* are the two small families of pitcher-plants, *Sarraceniaceæ* and *Nepenthaceæ*, both comprising carnivorous plants. These plants are distinguished for the possession of pitcher-shaped cavities, produced by various modifications of the leaf and containing watery liquids holding proteolytic enzymes in solution, by means of which they digest the bodies of such insects as are destroyed in the liquid, the digested albuminoids then being absorbed as food through the leaf-surface. Besides these enzymes, the leaves frequently secrete poisonous or intoxicating baits, which first attract, then stupefy the insects, so that they fall into the digesting solution. Quite a number of these plants have been used as aboriginal medicines, such uses having been suggested probably by their strange forms and habits. Some of them have been found more or less active, and are employed to a moderate extent in regular medicine.

Tunis regards the proteolytic enzyme of nepenthes as the most active known, as well as one of the most stable, resisting powerfully the action of alkalies and of high temperature. True peptone has been found in the product of its digestion.

Sarracenia (*American pitcher-plant*, *Side-saddle plant*, *Huntsman's-*, *Water-*, *Fly-*, *Eve's-*, *Forefather's*, or *Indian-cup*, *Indian-pitcher*, *Sarracenie*) is the plant, *Sarracenia purpurea* L., of eastern North America. It grows in bogs, from an obliquely conical rhizome, which is about 25 Mm. (1 In.) or more long, reddish-brown externally, brownish-white internally, bearing numerous thin, nearly simple, toughish roots, its fracture short and not colored blue by iodine solution, inodorous, bitter, and somewhat astringent. The leaves are radical, 15 to 20 Cm. (6 or 8 In.) long, the upper or stipular part of the petiole, together with the stipules, converted into a pitcher-shaped body which is sharply winged on the inner side, and bearing the leaf-blade as a roundish, heart-shaped hood. The solitary, nodding flower is 1½ to 2 inches broad and borne on the summit of a stout scape which is usually a foot or more long. The leaves are bitter, but less so than the rhizome. The plant contains the alkaloid *sarracenine*, very similar in characters and properties to veratrine, and about 0.16 per cent. of a volatile alkaloid bearing some resemblance to coniine. The yellow coloring-matter has been described as *sarracenic acid*, and *acrylic acid*, which is volatile, has also been reported. Sarracenia is said to possess the properties of a nervous and circulatory stimulant, mild tonic, diuretic, and laxative; but it is of little value in medicine. The drug has been employed to some extent in the treatment of atonic dyspepsia in doses of from 10 to 30 minims (0.6–2 Cc.) of a fluid extract, 3 times daily.

S. flava L. (*Trumpet-plant*, *Trumpet-leaf*, *Yellow trumpet*, *Huntsman's horn*, *Yellow-flowered water-cup*, *Pitcher-plant*, or *Side-saddle flower*), and *S. variolaris* Mx. (*Smallpox plant* or *Spotted trumpet-plant*), both of the southeastern United States, and both possessing much more slender, erect leaves than *S. purpurea*, are largely used as bitter tonics and antispasmodics in domestic practice. The last-named, because of its white-spotted leaves, has been fancifully administered in the treatment of smallpox. Many species of *Nepenthes* L., the *East Indian pitcher-plant*, are variously employed, and the water abstracted from their leaf-pitchers is an article of commerce in the East Indies. The leaves and root of *N. Boschiana* Krthls. is especially employed, chiefly as an astringent.

DULCAMARA.—Dulcamara.

Stipites dulcamaræ. — Bittersweet, True bittersweet, Woody nightshade, Blue bindweed, Poison berry, Wolf-grape, Morrel, Skawcoo, E.; *Tiges de-douce-amere (de morelle grimpante),* Fr.; *Bittersüss Stengel,* G.; *Dulcamaria Gloria,* Sp.; *Talos de Coce-Amargo, Uvc de Cao,* Port.

The dried young branches of *Solanum Dulcamara* L. (*Dulcamara flexuosa* Moench.—Fam. *Solanaceæ*).

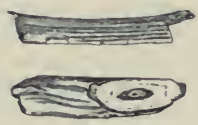
Dulcamaras is official in most pharmacopœias.

Origin.—A soft-shrubby plant, trailing or climbing, sometimes for several yards, over shrubbery, along streams, and in swamps and low grounds, throughout almost the whole of the north-temperate zone, and even extending into the tropics; probably naturalized in North America. Its appearance is well illustrated by the accompanying illustration. The potato-like flowers are of a bright-purple or even of a whitish-blue, and

Fig. 167.

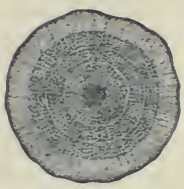
Solanum Dulcamara L.

Fig. 168.



Bittersweet (Nat.).

Fig. 169.



Transverse section.

the fruits are scarlet, shining and somewhat translucent, partly showing the numerous small seeds. The berries are more active than the twigs, their poisonous property probably residing in the seeds. They have been eaten by children, to whom they are highly attractive, with fatal effect, Those branches which are only one or two years old, and which have only partially developed their corky layer, should be collected, in the non-leafy stage.

Description.—Usually occurring in short sections, with a hollow center; about 5 Mm. (⅕ In.) or less thick, cylindraceous, somewhat angular, striate, more or less warty, externally pale-green or greenish-brown, marked by alternate leaf-scars, internally light-green, with 1 or 2 concentric circles of green or yellowish fibrovascular bundles; odor slight, narcotic; taste sweet and bitter, afterward slightly acrid. The bark contains numerous bast-fibers.

The cut rhizome of Saponaria quite closely resembles this drug, and we have known one to be sold for the other. Saponaria can be distinguished by its terete form, with rather regular wrinkles, instead of the unequal angles of Dulcamara, and by its circular nodes and opposite branching, instead of the alternate leaf-nodes of Dulcamara. Hop-stems are said to be sometimes substituted, but are readily distinguished by their rough surface and opposite leaf-scars. The stems of the false *Climbing bittersweet* (*Celastrus scandens*) are not hollow and are more woody in texture.

Constituents.—The constituents are dulcamarin, solanine, gummy, waxy, and resinous matters, and benzoic acid. *Dulcamarin* (*picroglycion* or *dulcarin*, $C_{22}H_{34}O_{10}$) is a bitter glucoside which leaves a persistent after-taste, is soluble in water, alcohol, and acetic ether, but not in ether or chloroform, and with dilute acids splits into glucose and tasteless brown dulcamaretin ($C_{16}H_{26}O_6$). *Solanine* ($C_{42}H_{87}NO_{15}$ or $C_{52}H_{92}NO_{18}$), widely distributed in the genus *Solanum*, and even elsewhere in the family, is a feebly bitter

alkaloidal principle of hot taste, crystallizing in rectangular prisms. It is soluble in 8000 parts of boiling water, in 125 parts of boiling alcohol, freely in amyl alcohol, and in 4000 parts of ether. Its salts react acid and are more soluble. With dilute acids it separates into dextrose and *solanidine* ($C_{26}H_{41}NO_2$), a crystalline alkaloid. The solanine of commerce, and that which has been mostly studied, is obtained from potato sprouts, and may be somewhat different from that of Dulcamara. There is an oxydase ferment in the leaves, stems, and green berries.

Action and Uses.—Bittersweet possesses diuretic and diaphoretic properties, and when given in full dose acts as a sedative and hypnotic. Large amounts produce a sensation of dryness and constriction of the fauces, nausea and vomiting, headache, vertigo, and muscular tremors or convulsions. The circulation becomes enfeebled, the hands and face either pallid or cyanotic, and the temperature subnormal. When lethal doses of solanine are employed, they cause, in addition to the above symptoms, considerable renal irritation, the urine becoming diminished and containing hæmoglobin and numerous casts. The alkaloid *solanidine*, however, is free from irritant properties, and when employed produces, with this exception, the effects of solanine. Dulcamara is of little practical use in medicine. It is now principally employed in the treatment of acne, impetigo, and chronic eczema, for which conditions it is used both locally and internally. Formerly it enjoyed some repute in the treatment of chronic rheumatism, chronic bronchitis, and whooping-cough, and was said to possess anaphrodisiac properties. *Solanine* has been highly recommended in the treatment of the vomiting of pregnancy, spasmodic asthma, chronic cystitis, and various forms of neuralgia. Its administration is said to quiet the lancinating pains of locomotor ataxia, to relieve the pains of gastralgia and sciatica, and to control the tremors and overcome the exaggerated reflexes resulting from insular sclerosis of the cord.

Dulcamara may be given in substance in doses of from $\frac{1}{2}$ to 1 drachm (2–4 Gm.); the fluidextract, in doses of from 30 minims to 1 fluidrachm (2–4 Cc.); and the extract, in doses of from 5 to 10 grains (0.30–0.60 Gm.).

A decoction, made by boiling 1 ounce (30 Gm.) of the drug with 1 pint (480 Cc.) of water, may be given in doses of 1 or 2 fluidounces (30–60 Cc.), several times daily.

Allied Products (see also SOLANACEÆ).—*Solanum* L. is the largest genus of flowering plants. Its species have been reckoned at from 600 to 1200, and the larger number will doubtless be exceeded when all are known. Many of the species are useful in varied and important ways. Dulcamarin and solanine, or allied substances, occur in many, if not in most, species, so that some of them are elsewhere important drugs. Among such drugs, the best known are the two following:

S. Carolinense L. (*Horse-* or *Bull-nettle*, *Apple of Sodom*, *Band-briar*, *Treadleaf*), a perennial stellate-pubescent and yellow-prickly herb of North America, and extending into the tropics. It is disastrously fatal to cattle in our Southern States. Both the berries and the root are used. The former are nearly globose, 1.5 to 2 Cm. ($\frac{3}{5}$ to $\frac{4}{5}$ In.) in diameter, orange-yellow, smooth and somewhat shining, much wrinkled in drying, fleshy, 2-celled and many-seeded, the base enclosed by the persistent deeply 5-lobed, stellate-pubescent calyx, its lance-ovate lobes reaching nearly to the middle of the berry and about half as broad as long. These berries are nearly odorless except when bruised, and have a bitter-sweet taste. The root, sometimes a foot or more in length and nearly a half inch in diameter, is usually very crooked, though vertical in direction, usually with few and small branchlets, of a yellow-brown color, terete and irregularly longitudinally wrinkled, the bark thick and easily separating when dry. It has a narcotic odor and a bitter-sweet taste. Its starch-grains closely resemble those of the potato. The activity of the root appears to reside wholly in the bark. The active constituents appear to be two alkaloids, existing together to the extent of about 1.3 per cent. in the fruit, 0.4 per cent. in the root. About two-thirds of the alkaloid appears to be *solanine*, considered above. The remainder has been thought to be *solanidine*, but J. U. Lloyd believes it distinct, and has proposed that it be provisionally known as *solnine*. "It is practically insoluble in water and diluted ammonia water, soluble in diluted acids and cold chloroform, and crystallizes from boiling alcohol in needles resembling hydrastine. Its melting-point is 131° C. (267.8° F.)" (Lloyd). The same alkaloids are contained, in variable amount, in all parts of the plant. Small quantities of fat, resin, volatile oil, and other common plant-principles also occur. *Solanum Carolinense* closely resembles dulcamara in its action. It has been recommended in epilepsy, but is probably of little value in this condition. The dose of the fluid extract is from 10 to 30 minims (0.65–2 Cc.).

Juribeba, or *Juripepa*, is a highly prized native drug in Brazil. It is the root and berries of *S. insidiosum* Mart., and probably also of *S. Juripeba* Rich. Its properties and uses appear very similar to those of *S. Carolinense*, and the composition is probably the same.

S. nigrum L., the *Black-* or *Garden-nightshade, Hound's berry, Small morrel, Schwartzer Nachtschalten* (G.), *Morelle* (Fr.), is one of the most widely distributed and best known of weeds, and has slight narcotic properties, various animals having been poisoned by eating freely of it. Yet the herbage is said to be sometimes eaten as a potherb, after thorough cooking. The berries are poisonous.

Natre is the fresh herbage of *S. Gayànum* Phil., *S. tomatillo* Phil., and *S. crispum* R. et P., of Chili, containing 0.1 per cent. of solanine, and used for measles, scarlet fever, and other eruptive fevers.

S. Pseudoquina A. St. Hil. is used as a substitute for quinine. *S. stramonifolium* Jacq. is violently poisonous, and is used as an arrow poison in Guiana. *S. mammosum* L. and *S. grandiflorum* R. et P., of tropical America, are also quite poisonous. The fruits of *S. saponaceum* Dun. contain saponin, and are used as a soap-substitute. *S. Quitense* Lam., of Ecuador, is so distinctly sedative that it is chewed by the natives to allay toothache. *S. oleraceum* Vell. is also used to soothe pain and as a mild narcotic, although, when thoroughly cooked, its herbage serves as a potherb. *S. paniculatum* L. is used in South America as a tonic, antiblennorrhagic, antisyphilitic, diuretic, antiperiodic medicine, but particularly in vesical catarrh and as a drastic.

The poisonous properties of the genera are curiously intermingled with edible ones, these pertaining to almost all parts of the plants. The common potato, the tuber of *S. tuberosum* L., some South American varieties perhaps to be traced to a different parentage, has a nutritive composition of starch 80 per cent., albuminous matter 2.25 per cent., and a fractional percentage of fat, and is one of the most largely used of vegetable foods, yet its fruit and young purple shoots are poisonous, and even the potato itself under certain circumstances, as when very immature, or when exposed in the growing condition to the light and air, assuming a greenish-purple color, has proved poisonous, sometimes fatally so. The poisonous principle appears to be chiefly solanine, but there is also *solanidine* ($C_{40}H_{61}NO_2$), soluble in hot alcohol and with difficulty in ether, forming needle-shaped crystals which melt at 191° C. (375.8° F.). A yellow, horny, amorphous glucosidal alkaloid present in it has been called *solanein*. Its action, if any, is not known. Schnell reports that the percentage of solanine in potatoes is normally only 0.006 to 0.0065 per cent. A lot containing 0.038 per cent. (0.024 per cent. after cooking) caused wholesale poisoning at the Strassburg garrison. These potatoes, when sliced, showed black fungous spots, and these spots, assayed separately, showed a one-third larger percentage of solanine, whence it was concluded that the fungus promoted the development of the alkaloid, and potatoes so affected should be rejected. This raises a question as to whether the Irish plague, which resulted from the eating of fungus-infected potatoes, was really due to the poison of the fungus, as commonly supposed, or to the increased amount of solanine. The herbage of the potato is apparently not poisonous. The ripe fruit and the boiled herbage of even *S. nigrum* are eaten.

The fruits of *S. auriculum* Ait. are poisonous if green, edible if ripe. *S. incanum* L. is used, like rennet, to curdle milk. Several species yield edible fruits, notably the common *Egg-plant*, *S. melongena* L., *S. variegatum* R. et P., of the Andes, and *S. violæfolium* Schott., a creeping species of Brazil. Finally, it may be mentioned that the herbage of several species yields dyestuffs.

E.

ELASTICA, *U. S.*—India Rubber; Rubber.

Resina (*s. Gummi*) *elasticum.*—*Caoutchouc*, E., Fr. Cod.; *Kautschuk, Federharz*, G.; *Cahuchu, Goma elastica, Syringay*, Sp.

The prepared milk-juice of several species of *Hevea*, Aubl. (Fam. *Euphorbiaceæ*), known in commerce as *Para rubber.*

Origin.—The *Heveas* are large forest-trees of northern South America, east of the Andes, growing mostly in the vicinity of streams, and possessing very straight trunks, with a smooth or only slightly rough bark. They bear light-green, glaucous, trifoliolate leaves and small greenish flowers, followed by 3-celled capsules, a large oblong seed, of about the form and size of an olive, in each cell. The seeds must be germinated almost at once, at the point of production, for purposes of propagation, and the plants transported. The cultivation of these trees for the production of rubber has been instituted at various points. The rubber is gathered by gently tapping the bark with a small sharp-pointed pick. Care is taken not to penetrate to the wood, which leads to the entrance of a boring insect, which promptly destroys the tree. The milk-juice may therefore be regarded as a protection against such insects. The milk, which, when it exudes, has very much the color and consistency of cows' milk, is caught in small cups fastened to the bark. Twice a day, usually, the cups are emptied into a large vessel at the smoking station. Into the milk is dipped a flat wooden paddle, and the layer of milk caught upon it is held in a column of smoke, and dextrously turned to prevent dripping, until coagulated, when the operation is repeated, a large flask-shaped mass, the *bolacho*, at length accumulating upon the paddle; or, the mass may be suspended in the smoke and fresh milk poured over it as fast as coagulation occurs. This is afterward removed by making a suitable incision in its upper end. The smoke is made by burning, excluded from free access of air, palm fruits or some other oily or fatty fuel. The forming mass is sometimes alternately dipped into sand or other heavy adulterating substances, or heavy bodies are introduced. The freshly coagulated rubber is white, but soon turns yellow, brown, and at length black, the change occurring first at the surface, and gradually extending to the center. At the same time there is a loss of weight, owing to evaporation of water, so that it is deemed profitable to sell the rubber shortly after its production. The bolachos are now mostly cut up into small pieces before exporting, for the detection of adulteration.

Description and Properties.—In flask-shaped masses with a thin, flat central cavity, and a fissure and a large perforation at one end, or in irregularly cut pieces of the same; externally smoothish and blackish, internally varying gradually from brown to whitish toward the center, and showing a layered structure; often slightly porous; very tough and elastic, and requiring a very sharp knife to cut it, the elasticity increasing with the temperature; density, 0.92 to 0.96; heated at 125° C. (257° F.), or a little higher, it melts, but on cooling remains soft and elastic, congealing ultimately to a brittle mass; decomposing at higher temperatures and burning in the atmosphere with a luminous sooty flame; of a faint and peculiar odor; nearly tasteless.

India rubber is insoluble in water and dilute acids and alkalies; it softens and swells when treated with hot alcohol, and dissolves to a soft, jelly-like mass in carbon disulphide, stronger ether, oil of turpentine, and other hydrocarbons, notably in petroleum benzin, benzene, and in the empyreumatic oils obtained in the destructive distillation of India rubber; it dissolves more readily and completely in chloroform, and may be melted together with fats and fixed oils. When pure or nearly so, India rubber floats on water. Rubber tubing is apt to become brittle by use and on exposure, a change which Mareck (1881) found can be prevented by keeping the tubing under water, which is to be occasionally renewed; the outer layer of the rubber assumes a fatty appearance, becomes lighter, then darker, and is improved for practical purposes. A strong solution of India rubber or an ammoniacal solution of shellac may be employed as a *cement* for fastening rubber upon other material.

When finely divided, mixed with sulphur, and afterward heated, *vulcanized* rubber is obtained; this, however, is more generally prepared by softening or dissolving India rubber and combining it with sulphur. Vulcanized rubber is insoluble in the ordinary solvents of India rubber, and its elasticity is not materially affected by a low temperature. Compounds of India rubber and sulphur, with which tar, white lead, chalk, or other substances have been incorporated, form *hard rubber* and *ebonite*, which at an elevated temperature may be molded or rolled into sheets.

Composition.—The recent juice contains about 32 per cent. of caoutchouc, with wax, free acid, nitrogenous bitter substances, etc. The concrete juice usually contains also free carbon or soot, resulting from the smoking process. Pure caoutchouc is a hydrocarbon ($C_{20}H_{32}$), which on destructive distillation yields *caoutchoucin*, consisting of two or more polymeric volatile oils (C_9H_8), also oil of caoutchouc.

Uses.—Rubber is never employed in internal medicine, but has a wide range of uses in the arts and in surgery. It is now largely used in the manufacture of plasters, trusses, orthopedic braces, bougies, catheters, artificial hands, ears, and noses, and the "rubber tissue," sheeting, and bandages prepared from it are almost indispensable in surgical practice.

Other Varieties of Rubber.—The list of plants which have yielded commercial rubber is a long one. In the *Druggists' Circular* for August, 1894, the present writer published a list of 11 in the *Euphorbiaceæ*, 9 in the *Moraceæ*, and 18 in the *Apocynaceæ*, but that list was far from complete. The product of a dozen or twenty species is important in commerce. It is estimated that the total annual production of rubber is about 100 millions of pounds, about three-fifths or more of which is of the sort above considered. Nearly a third comes from central Africa. African rubber is chiefly the product of several species of *Landolphia* (woody vines of the Fam. *Apocynaceæ*), of which about 40 species are known, and of *Kicksia Africana* Benth., in the same family. Next to these, the most important rubber producer is the *Castilloa elastica* Cerv. (Fam. *Moraceæ*), which produces the Central American or Panama rubber. It is a slender tree, only about 50 or 60 feet in height, with a few long horizontal branches near the top. It yields an edible fruit. The percentage of caoutchouc in the milk is about the same as in the Para sort, and the rubber is of very good quality. Not much can be expected before the twelfth to fifteenth year. The trees yield for a very long term of years. They can be tapped twice a year, and yield from 1 to 2 pounds each time. The rubber is prepared in various ways, rarely by heating and smoking. The common method is to run it into holes in the ground, sometimes into a barrel, and to use alum or the juice of a native plant to cause coagulation. Even ashes and earth are sometimes used, yielding a vile-smelling "nigger-head" mass. It is often precipitated by pouring into water, but a spongy mass results, from which the water must be squeezed. It is regarded as practicable to secure this sort by extraction of the twigs and leaves. Eight kinds are reported as being collected in Mexico, but this is the only one of importance. A very good Brazilian rubber, produced in considerable quantity, is that known as Mangabeira, Pernambuco, or Bahia rubber, from *Hancornia speciosa* Gomez (Fam. *Apocynaceæ*). This is a small tree, about 15 to 20 feet high, and yields an edible, plum-like fruit. The *Kew Bulletin* states that it is tapped at from 5 to 6 years of age, and yields from 2 to 10 pounds at a tapping. It is prepared, like that of *Castilloa*, in various ways. Manicoba rubber, often called Ceara rubber, is the product of *Manihot Glaziovii* Müll. Arg. (Fam. *Euphorbiaceæ*), also a native of Brazil, and a relative of *Hevea*. It is a very small tree, and begins to yield in the third or fourth year, when the annual yield is about 50 Gm. per tree, increasing in half a dozen years to from 5 to 7 times this amount. It continues to bear for many years, it is said as many as 50. This rubber is very inferior to the official.

East Indian or Assam rubber is from *Ficus elastica* Roxb. (*Urostigma e.* Miq.—Fam. *Moraceæ*), the common rubber plant of house-cultivation. Very many other species of *Ficus*, in both the old and new worlds, are capable of yielding rubber. Fiji rubber is the product of *Alstonia plumosa* Labill. (Fam. *Apocynaceæ*).

Penang and Borneo rubber is from *Urceola elastica* Roxb. and *U. esculenta* Benth. (*Chavannesis e.* DC.—Fam. *Apocynaceæ*).

Very many artificial substitutes for rubber have been prepared, and some of them, especially those with some genuine rubber as a basis, are largely used. None of them is a good substitute for the genuine, and the use of none is to be thought of for pharmaceutical purposes.

ELATERINUM, *U. S., Br.*—Elaterin.

Elaterin, G.; *Elaterine, Elatine*, Fr.; *Elaterina*, Sp.

A neutral principle ($C_{20}H_{28}O_5 = 345.60$), obtained from elaterium, a substance deposited by the juice of the fruit of *Ecballium Elaterium* (L.) A. Richard (Fam. *Cucurbitaceæ*).

Elaterin, which is considered as the anhydride of elateric acid, does not pre-exist in the juice of the squirting cucumber, but results from the hydrolysis of a glucoside by a ferment, both of which are present in the juice, the hydrolysis occurring during the sedimentation of the latter. It is chiefly obtained from elaterium by treating the same with boiling alcohol and precipitating the elaterin from the resulting solution by addition of water and then purifying it by washing with ether and recrystallizing from absolute alcohol. Elaterin may also be extracted from elaterium with hot chloroform and precipitated by addition of ether, being subsequently recrystallized from alcohol or chloroform.

A more complicated process for obtaining elaterin consists in precipitating the ferment

from the juice, freshly expressed, by means of alcohol, extracting and purifying the glucoside, and then bringing the two together in form of solution, when elaterin will be produced together with dextrose.

Elaterin occurs in small white hexagonal scales or prismatic crystals, without odor, and permanent in air. It has a slightly acrid, bitter taste, and is soluble at 25° C. (77° F.) in 262 parts of alcohol; also soluble in 22 parts of chloroform, 272 parts of benzene, and 200 parts of amyl alcohol, but requiring 318 parts of ether for solution; also soluble in 75 parts of alcohol at 60° C. (140° F.), U. S. Schmidt states that elaterin is soluble in 15 parts of cold or 2 parts of boiling alcohol and in 290 parts of ether. It is insoluble in glycerin. Elaterin is dissolved by solutions of the alkalies, and reprecipitated on supersaturating with an acid. "Elaterin is neutral to litmus-paper and melts at 216° C. (420.8° F.), forming a yellowish-brown liquid, and when ignited burns without residue. If a crystal of elaterin be added to a little hydrochloric acid and this evaporated to dryness, the residue washed with hot water, and afterward treated with sulphuric acid, a brownish-red (amaranth) color will be produced. Concentrated sulphuric acid dissolves elaterin, forming a yellow solution, which gradually changes to scarlet."—U. S. Elaterin imparts a green color to Fröhde's reagent and a blue color to vanadin-sulphuric acid, which afterward changes to green, and then to brown. Dissolved in melted phenol, it develops a crimson color on addition of strong sulphuric acid, which rapidly changes to scarlet. Elaterin is not precipitated from its alcoholic solution by tannic acid, mercuric chloride, or platinic chloride, showing absence of and difference from alkaloids.

Pharmaceutical Preparation.—Trituration of Elaterin, U. S. P.

Action and Uses.—Elaterin is employed under the same conditions and for the same purposes as Elaterium (which see). The dose is from $\frac{1}{30}$ to $\frac{1}{20}$ grain (0.002–0.003 Gm.), best given in pill-form.

ELATERIUM, *Br.*—Elaterium.

Extractum Elaterii. Elaterium, Fr., G.; *Elatterio*, It., Sp.

A sediment from the juice of the fruit of *Ecballium Elaterium* (L.) A. Richard (*Momordica E.* L.; *E. officinale* Nees; *E. agreste* Reich.; *E. cordifolium* Moench.—Fam. *Cucurbitaceæ*).

Origin and Preparation.—This fruit (*Ecballii Fructus, Cucumis asininus, Cucumis agrestis.—Squirting* or *Wild cucumber*, E.; *Springgurke, Esels-Kürbis, Spritzgurke*, G.; *Concombre sauvage purgatif d'âne*, Fr.; *Cohambrillo amargo*, Sp.) is the product of a succulent, bristly, trailing, tendril-bearing, perennial, squash-like vine, abundant in dry waste places in the Mediterranean basin, and slightly cultivated for medicinal purposes in various European countries. The fruit is nodding from the recurved stalk, 5 Cm. (2 In.) or less in length, and half as thick, oblong, and somewhat tapering above, pale-green, beset with fleshy prickles and 3-celled. As the fruit matures, a bitter, watery, or slightly mucilaginous juice is developed in increasing amount and collects in a basal cavity, with the seeds immersed in it, a high outward tension finally existing. In this condition the slightest disturbance causes violent rupture of the base of the fruit, and the discharge of the juice and seeds, a provision, doubtless, for the protection of the latter against being eaten, as well as for dissemination. The highly and promptly purgative properties of the juice are doubtless designed for the same purpose, in case of the ingestion of it with the seeds. This peculiarity necessitates the collection of the fruit just previous to maturity, for the extraction of elaterin. Various processes are employed for this purpose, but all depend upon the requirement that only the thin, watery juice which exudes spontaneously be used, and

Fig. 170.

Ecballium Elaterium.

that the impure elaterin be allowed to subside, then be quickly separated, drained, and dried, this sediment constituting *elaterium.*

For its extemporaneous preparation, the following process is recommended: Take of squirting cucumber fruit, very nearly ripe, 1 pound. Moisten the surface with water, to prevent the juice from adhering. Cut the fruit lengthwise and lightly press out the juice. Rinse off the cut surfaces with water. Strain the liquid through a hair-sieve and set it aside to deposit. Carefully pour off the supernatant liquor, pour the sediment on a linen filter, and dry it on porous tiles with a gentle heat. The decanted fluid may deposit a second portion of sediment, which can be dried in the same way. With an increased pressure, a larger amount of juice and of deposit is obtained, but the latter is then of inferior quality. Exposure of the drying elaterium to the sunshine should be avoided. Clutterbuck obtained only 6 grains of elaterium from 40 specimens of squirting cucumber; with slight pressure, 40 pounds of the fruit will generally yield $\frac{1}{2}$ ounce, and in warm, dry seasons even $\frac{3}{4}$ ounce of elaterium.

Description.—Elaterium is in light, friable, flat or slightly incurved cake-like fragments, frequently marked on their surfaces with the impression of the linen or paper on which they were dried. When fresh, it has a pale-green color, changing by age to gray, and then often containing minute sparkling crystals on the surface. It breaks with a fine granular fracture, and has a slight tea-like odor and an acrid and bitter taste. It does not effervesce with acids; a cooled decoction of it is not colored blue or is but slightly tinged by solution of iodine, showing the presence of but very little starch. It yields half its weight to boiling rectified spirit; and this solution, on being concentrated and added to a warm solution of potassium hydroxide, deposits on cooling not less than 20 per cent. of elaterin in colorless crystals.

Constituents.—Elaterium consists of 44 per cent. of elaterin (see ELATERINUM), 17 per cent. of green resin, 6 per cent. of starch, etc. Besides these, the juice of the fruit and herb contains *prophetin*, a crystallizable bitter yellow glucoside; *ecballin* or *elateric acid* ($C_{20}H_{34}O_4$?), bitter, acrid, amorphous, resin-like, soluble in 20 parts of water, and in alcohol, ether, and alkaline hydroxides; *hydro-elaterin* ($C_{20}H_{30}O_6$?), yellow, amorphous, not bitter, and soluble in water, alcohol, and ether; and very bitter amorphous *elaterid* ($C_{20}H_{32}O_{12}$?), which is soluble in dilute alcohol, but not in water or ether, and is precipitated by tannic acid.

Action and Uses.—Elaterium is an irritant hydragogue purge. That is to say, it produces large watery stools and is distinctly drastic in its influence. As it is very irritating to mucous membranes with which it comes in contact, it ought not to be given if there is present irritation or inflammation of the stomach or bowels. Its field of usefulness is to produce free watery evacuations in cases of dropsy, and also to relieve congestion at the base of the brain and in the lungs, when congestion of these parts is produced by renal or cardiac disease.

Elaterium is not a purge which is to be used for the purpose of moving the bowels under ordinary circumstances. Where obstinate constipation is present, it sometimes produces watery stools, but leaves in the bowel considerable quantities of hardened fecal matter. It is thought by some that elaterium causes a greater elimination of urea through the bowels, when it produces its purgative effect, than any other hydragogue cathartic, and that it is therefore particularly advantageous in cases of Bright's disease with dropsy.

The dose of elaterium is $\frac{1}{6}$ grain (0.01 Gm.), given with a little confection, in a powder with sugar of milk, in capsule or in pill.

ELEMI.—Manila Elemi.

Resina (*s. Gummi*) *Elemi.*—*Elemi*, G.; *Elémi, Resine elemi*, Fr.; *Goma de limon*, Sp. A concrete resinous exudation from *Canarium commune* L. (Fam. *Burseraceæ*).

Origin.—The name of elemi has been given to many resinous products which have from time to time appeared in commerce. Some of them, of semisolid consistence, have been called *soft elemis;* others, about like common rosin, or harder, are known as *hard elemis.* To the latter class belongs that here considered. It is obtained, chiefly in the Philippines, from incisions in the bark of a tall tree, growing also in the Moluccas and other of the old-world tropics. Artificial heat is said to be used to make the juice flow more freely. The fruit of this tree is said to be the cathartic *Java almond* or *Amendra.*

Description.—Manila elemi is in soft granular transparent masses when fresh, but is generally met with in the shops in solid pieces, which are externally pale lemon-yellow and clear, internally opaque, nearly white, and mixed with chips and other impurities. It breaks with a dull granular fracture and readily fuses to a transparent liquid. Moistened with alcohol, it disintegrates and shows a large number of small acicular crystals. It has a strong aromatic, somewhat terebinthinate odor, and a warm, aromatic, and acrid taste.

Constituents.—About one-fourth of its weight is *amyrin*, separable into *α-amyrin* and *β-amyrin*. Most of the remainder is *amorphous resin*, with 10 to 15 per cent. of volatile oil. *Elemic acid* ($C_{35}H_{46}O_4$), *breïdin*, *bryoidin*, and an amaroid, are present in small amount.

Action and Uses.—Elemi is rarely employed in medicine in this country, but in Europe is used to some extent in the preparation of plasters and ointments, which are said to be advantageous as a dressing for fissures, blisters, and ulcers. The drug possesses properties which are analogous to those of turpentine, but it is never employed in internal medicine.

Other Elemis.—Karl Dieterich, who has recently investigated these resins, regards a number of others as being "genuine Elemi," as follows: Yucatan or West Indian Elemi, from *Protium Icicariba* (DC.) March. (*Icica I.* DC.), which is usually soft. Part of this is probably derived, as is Mexican or Vera Cruz Elemi, from *Amyris Plumieri* DC. (*Amyris elemifera* L.); Rio or Brazilian Elemi, from various species of *Protium;* African Elemi, from *Canarium Zephyricum* March. Very similar to these are the Tacamahac resins, East Indian from *Calophyllum inophyllum* L. and Bourbon from *C. Tacamahaca* W. Similar, but with the odor of *Olibanum*, are the following: Cayenne incense or West Indian tacamahaca, from *Protium heptaphylla* March. and Resin of accume, from unknown *Burseraceæ* of the West Indies. Mauritius Elemi, much like the Manila, is from *Colophonia Mauritiana* Commerson. *Calophyllum* is in the *Guttiferæ*, all the others in *Burseraceæ*, except that Engler has, we think with poor judgment, referred *Amyris* to the *Rutaceæ*.

Canarium strictum Roxb. is the source of the *Black dammar* of India.

ELIXIR ADJUVANS, *U. S.*—Adjuvant Elixir.

Elixir adjuvant, Fr.; *Gewürzhaftes Lakritzenelixir*, G.

Preparation.—Fluidextract of glycyrrhiza, 120 Cc.; Aromatic elixir, 880 Cc. Mix them, and filter if necessary.—U. S.

Adjuvant elixir is of a yellowish-brown color and has a very sweet, aromatic taste.

Uses.—It is intended as a vehicle to disguise the unpleasant saline or bitter taste of medicines, but should not be used in connection with acid liquids, as these will cause precipitation.

ELIXIR AMARUM, *P. G.*—Bitter Elixir.

Elixir amère, Fr.; *Bitteres Elixir*, G.

Preparation.—Extract of absinth, 2 parts; oil-sugar of peppermint, 1 part; water, 5 parts; aromatic tincture, bitter tincture, of each, 1 part. Triturate the extract and oil-sugar with the water until dissolved, add the tinctures, and filter.—P. G.

This preparation should be allowed to stand 2 or 3 days before filtration, and then yields a clear dark-brown liquid.

Uses.—It is used as a bitter tonic.

ELIXIR AROMATICUM, *U. S.*—Aromatic Elixir.

Simple Elixir, E.; *Elixir aromatique*, Fr.; *Aromatisches Elixir*, G.

Preparation.—Compound spirit of orange, 12 Cc.; syrup, 375 Cc.; purified talc, 15 Gm.; alcohol, distilled water, of each a sufficient quantity to make 1000 Cc. To the compound spirit of orange add sufficient alcohol to make 250 Cc. To this solution add the syrup in several portions, agitating after each addition, and afterward add, in the same manner, 375 Cc. of distilled water. Mix the purified talc intimately with the liquid and then filter through a wetted filter, returning the first portions of the filtrate until it passes through clear. Lastly, wash the filter with a mixture of 1 volume of alcohol and 3 volumes of distilled water, until the product measures 1000 Cc.—U. S.

To prepare 2 pints of aromatic elixir will require 3 fluidrachms of compound spirit of orange, 12 fluidounces of syrup, 8 fluidounces of alcohol, ½ ounce of purified talc, and sufficient distilled water to make the volume 32 fluidounces.

Uses.—This preparation is very largely used as a vehicle.

ELIXIR AURANTII COMPOSITUM, *P. G.*—Compound Elixir of Bitter Orange.

Elixir d'orange amère composé, Fr.; *Pomeranzenelixir*, G.

Preparation.—Bitter-orange peel, in very coarse powder, 20 parts; cassia, in coarse powder, 4 parts; potassium carbonate, 1 part; extract of gentian, extract of absinth, extract of buckbean, extract of cascarilla, of each, 2 parts; sherry wine, a sufficient quantity to make 100 parts. Macerate the orange peel, cassia, and potassium carbonate with 100 parts of sherry wine for 8 days in a closed vessel at a temperature of 15°–20° C. (59°–68° F.); express, add sufficient sherry wine to bring the weight of the liquid up to 92 parts, and in this dissolve the extracts. After standing a few days, filter.—P. G.

Uses.—This elixir is used as a bitter tonic and as a vehicle.

ELIXIR FERRI, QUININÆ, ET STRYCHNINÆ PHOSPHATUM, *U. S.*—Elixir of Iron, Quinine, and Strychnine Phosphates.

Elixir des phosphates de fer, de quinine et de strychnine, Fr.; *Elixir von phosphorsauren Eisen, Chinin und Strychnin*, G.

Preparation.—Soluble ferric phosphate, 17.5 Gm.; quinine, 8.75 Gm.; strychnine, 0.275 Gm.; phosphoric acid, 2 Cc.; ammonium carbonate, in translucent pieces, 9 Gm.; alcohol, 60 Cc.; acetic acid, 28.65 Gm.; distilled water, aromatic elixir, each a sufficient quantity to make 1000 Cc. Dissolve the quinine and strychnine in the alcohol, then add the phosphoric acid and 350 Cc. of aromatic elixir. Add the acetic acid to the ammonium carbonate, contained in a suitable vessel, and when solution is complete add enough distilled water to make the product measure 50 Cc. Mix the neutral solution of ammonium acetate with the solution of the alkaloids, and add sufficient aromatic elixir to make the liquid measure 850 Cc. Dissolve the ferric phosphate in 30 Cc. of distilled water, by the aid of a gentle heat, and if the solution be acid to litmus-paper neutralize exactly with ammonia-water, and add sufficient aromatic elixir to make the product measure 120 Cc. Finally, mix the two solutions and filter, if necessary.—U. S.

To make a gallon of the official elixir, dissolve 512 grains of quinine alkaloid and 16 grains of strychnine alkaloid in 8 fluidounces of alcohol, add 48 fluidounces of aromatic elixir, and then 2 fluidrachms of official (85 per cent.) phosphoric acid. Add 568 grains of ammonium carbonate, in clear firm pieces, to 1792 grains of 36 per cent. acetic acid, and when solution is complete add sufficient distilled water to bring the volume up to 6 fluidounces. Mix the ammonium acetate solution with the solution of quinine and strychnine phosphates, and add sufficient aromatic elixir to make the liquid measure 112 fluidounces or 7 pints. Dissolve 1024 grains of soluble phosphate of iron in 4 fluidounces of distilled water by the aid of a gentle heat, and, if necessary, neutralize the solution carefully with ammonia-water, and add sufficient aromatic elixir to bring the volume up to 16 fluidounces. Finally, mix the two solutions.

The finished product will represent in each cubic centimeter 0.00875 Gm. of quinine and 0.000275 Gm. of strychnine, in the form of phosphates, and 0.0175 Gm. of soluble phosphate of iron, or in each teaspoonful $\frac{1}{2}$ grain of quinine, $\frac{1}{64}$ grain of strychnine, and 1 grain of iron phosphate.

Elixir of iron, quinine, and strychnine phosphates, prepared by the above formula, is of a pale greenish-yellow color, and has a pleasant aromatic odor and a bitter taste. It should be kept in a dark place and be dispensed in amber-colored bottles, as all elixirs containing soluble phosphate of iron darken materially if exposed to light.

If the official directions are carefully followed, no difficulty will be experienced in obtaining a perfectly clear preparation, which is miscible in all proportions with water and keeps well at all seasons. Elixir of the phosphates of iron, quinine, and strychnine has been very popular with physicians for over a quarter of a century, and its introduction into the Pharmacopœia is particularly desirable to insure uniformity in composition. The various elixirs of the above name placed on the market by the different manufacturing firms do not agree in composition nor in strength of the more active ingredients, and in some cases the salts are not even present as phosphates. If an elixir is desired containing the quinine and strychnine as phosphates, in perfect solution with phos-

phate of iron, and yet not unpleasantly acid (for a large excess of phosphoric acid will accomplish the purpose), some other substance must be added which shall prevent precipitation. Ammonium acetate has been found to produce the best results, and to yield an elixir which remains clear at the freezing temperature. The very small proportion of ammonium acetate required is not in any way hurtful, and need not be considered any more than the alkali citrate in the phosphate of iron.

Uses.—This elixir affords a palatable form in which to administer its three important ingredients. It is a valuable tonic and stimulant, to be given during convalescence from exhausting diseases, or in any condition characterized by anæmia, nervous debility, general asthenia, or impaired appetite. The dose is from 1 to 2 drachms (4–8 Cc.).

ELIXIRIA.—Elixirs.

Elixirs, Fr.; *Elixire*, G.

The word "elixir" is of ancient origin, and, according to the late Charles Rice, was derived by the Arabs from the Greek word *ξήριον*. It was formerly used by chemists to designate the wonderful transformation-powder, a pinch of which was claimed to be sufficient to convert large quantities of base metal into silver and gold. Gradually the term was applied also to liquids claimed to possess the same magical powers, and still later the word "elixir" was used to designate certain compound tinctures possessing rare medicinal properties, as, for instance, Elixir ad longam vitam, which was supposed to induce longevity. In this latter sense the term elixir is still used to some extent in continental Europe, and, as a rule, such preparations are characterized by an unpleasant taste. In modern American pharmacy the word has come to mean an entirely different class of preparations, the distinguishing features of which are a pleasantly aromatic sweet taste and the presence of alcohol, varying from 20 to 25 per cent. by volume. Prior to 1865 only two elixirs of this kind were used to any extent in this country—namely, elixir of calisaya and elixir of ammonium valerianate. Through the efforts of enterprising manufacturers the list of elixirs was rapidly augmented, and reached its height between 1870 and 1875. Gradually, however, a reaction set in, and at the present day many once-popular elixirs have fallen into disuse. There can be no doubt that a sweet, aromatic, and slightly alcoholic liquid forms a pleasant vehicle for many remedies, but the presence of alcohol in some instances is positively injurious, and, moreover, the active ingredients are frequently present only in minute quantities. The U. S. P. recognizes but three elixirs—adjuvant elixir, the aromatic elixir, and the elixir of iron, quinine, and strychnine phosphates—the two former chiefly as bases for the ready preparation of many others.

As it is desirable in many instances to impart a color to the elixir, it should be borne in mind that not all coloring-agents are equally well suited for acid and alkaline liquids; for the former class as well as for neutral liquids, the National Formulary recommends the simple or compound tincture of cudbear, of either of which 2 drachms will suffice to color a pint of elixir. For alkaline liquids it is best to use a solution made as follows: carmine No. 40, 60 grains; glycerin and distilled water, each, 4 fluidounces; ammonia water, a sufficient quantity; triturate the carmine with the water, gradually adding ammonia water until the carmine has all been dissolved and a dark-red liquid is obtained; to this add the glycerin and mix (Lloyd).

EMPLASTRA.—Plasters.

Emplâtres, Fr.; *Pflaster*, G.; *Empiastri*, It.; *Emplastos*, Sp.

Plasters are preparations intended for external application, which, although firmer and more tenacious than cerates, become adhesive by the heat of the body, and may be made to serve the purpose of offering both support and medication to the parts to which they are applied. They are firm solids at ordinary temperature, and cannot be spread without the aid of heat, but retain a certain degree of flexibility when applied to the body. The base or mass of nearly all the official plasters is either simple lead plaster or a mixture of the same with wax, resin, and gum-resins; in large manufactories a rubber-mass is specially prepared from caoutchouc and certain aromatic resins and vegetable powders, which is to be preferred in some cases on account of its flexibility and adhesiveness. In the preparation of the rubber plaster-base the crude India rubber of commerce

is first freed from impurities by steaming and continuous washing with warm water in suitable machinery until all foreign matter has been removed, after which it is repeatedly passed between heavy steel rollers kept at a temperature of about 35° or 37° C. (95° or 98.6° F.); during this kneading process the rubber gradually softens and assumes a plastic condition which fits it admirably for the incorporation of very finely powdered olibanum, orris root, and resin or Burgundy pitch, this being also effected between warm smooth rollers.

Some authorities contend that plasters made with a rubber base are wholly inefficient where systemic or even endermatic effects are desired, since, as they claim, the rubber combination does not permit the release and subsequent absorption of the medicinal agent present. Opinions are divided on this point, and while there is no doubt that a volatile or a fatty vehicle will permit the absorption of any medicinal agent in admixture more readily than an insoluble mass of rubber, resin and wax, or lead oleate, many physicians claim to have observed positive good effects from rubber-base plasters, and the testimony of many hundred laymen is in favor of this decidedly more pleasant and convenient form of plasters.

As in the case of ointments, plasters may be divided into three groups with regard to their therapeutic action:

1. Plasters intended to exercise a supportive, protective, antiseptic, counterirritant, or vesicant effect. These will act only epidermatically, and a mass possessing the property of ready and continued adhesiveness is to be preferred; hence rubber combinations and the official resin plaster are well adapted for this group, the former possessing the advantage of greater adhesiveness, especially in the presence of moisture.

2. Plasters intended to produce an endermatic effect, such as anodyne, astringent, alterative, sedative, or stimulant. This group includes the official plasters of arnica, belladonna, lead, opium, and pitch; and while lead oleate, together with its admixtures of resin or soap, is preferred by many as a vehicle, it is safe to assume that the large quantities of plasters of this group made with rubber-mass are not used without good results.

3. Plasters intended for constitutional and systemic effects. As these require penetration not only into but also through the skin, it is absolutely necessary that the vehicle be one of recognized absorbability. The only official representatives of this group are mercurial plaster and ammoniac plaster with mercury, neither of which it is claimed possesses much value on account of the vehicle employed.

The preparation of plaster-masses by pharmacists is very similar to that of cerates, being preferably conducted with water-bath heat, those constituents having the highest fusing-point being first introduced into the pan or dish, and others of greater fusibility being gradually incorporated. All wholly or partly volatile substances, as oleoresins or essential oils, must be added last, and non-fusible substances must be incorporated in the form of very fine powder whenever possible; as gum-resins are frequently added to plaster mixtures, and as they cannot be reduced to fine powder without injury, they must either be treated in coarse powder with alcohol, and the resulting solution of resinous matter then evaporated to a syrupy consistence, as in the case of asafetida, myrrh, and galbanum, or be emulsionized with diluted acetic acid and then evaporated until the liquid hardens on cooling, as in the case of ammoniac. In either case the concentrated liquid should be added to the fused mixture when it begins to cool, the mass being well stirred to insure uniform distribution.

Fluid and solid extracts must be incorporated as in the case of ointments, the former after evaporation to a syrupy consistence, the latter after softening with a little water or diluted alcohol, as the case may be. As in the case of ointments, the extinguishment of metallic mercury in plasters is mostly effected by trituration with mercuric oleate.

If any foreign matter, such as sand, pieces of wood, and the like, should be found in the melted plaster, this is best removed by decantation or straining, which must always be done before the insoluble and non-fusible substances are added; if straining be resorted to, it will be advisable to perform this operation with the smallest bulk possible, the strained material being always received in a warm pan or dish.

If plasters are to be preserved for stock, they are usually rolled into cylindrical pieces of convenient thickness weighing about 4 or 8 ounces; this operation is performed on a slab or board previously moistened with water or expressed oil of almond; these sticks or rolls should be wrapped in waxed or paraffined paper to protect them from the air.

Although, with two exceptions, the term plaster is officially applied to the mass or combination to be spread upon leather or muslin, it is more extensively used in trade to designate the finished spread plaster, ready for application. The spreading of plasters has almost entirely passed out of the hands of pharmacists, hence it does not now appear necessary to describe and illustrate the various appliances which thirty-five or forty years ago were considered a very essential and important part of every educated pharmacist's outfit. Plaster-masses, official and otherwise, may now be purchased of reliable quality, spread on muslin or other material, in one- and five-yard rolls, or in definite and convenient sizes, from large manufacturers, and there is to-day no more reason why a pharmacist should make and spread belladonna plasters than that he should return to the spreading of adhesive plaster, as was done many years ago. Moreover, plasters are prescribed but rarely now by physicians, and, when some new combination is ordered, the pharmacist will probably have little difficulty in spreading a plaster of fair quality and appearance by following the few general directions here given.

For extemporaneously spread plasters the best material is soft white leather, the kind known in the trade as plaster skin. A piece should be cut 1 inch larger each way than the size of the plaster ordered; thus a 4 × 6 plaster would require a piece of leather 5 × 7 inches; now prepare 4 strips, $\frac{1}{2}$ inch in width, of stiff paper, preferably glazed, and having previously prepared the plaster-mass on a water-bath, as directed above, apply the paper strips to the rough side of the plaster skin in such a manner that the desired space shall remain uncovered, and carefully pour the melted plaster-mass on the leather, smoothing the surface with a warm spatula, or by holding the spread plaster near a stove or furnace-register and allowing the soft material to run smooth. Then, having placed the spread plaster on a level surface, with a quick motion remove the paper strips before the plaster surface hardens, so that a clean half-inch margin around the plaster proper may be obtained. In place of a spatula, the roller shown in Fig. 171 may be used with advantage for smoothing the spread plaster-mass; it should be dipped in hot water, so as to become warm, before it is used, and then be moistened with a mixture of 1 volume of glycerin and 2 volumes of water to prevent adhesion.

Fig. 171.

Plaster-roller.

If the paper strips be attached before the melted mass is ready to be applied, the paste is likely to dry out, when subsequent removal of the paper from the rough leather becomes difficult, and hence some pharmacists prefer to moisten the strips with a damp sponge just previous to spreading the plaster-mass; this plan has been found very advantageous. Instead of using paper strips, some prefer to cut a frame of thin cardboard, with a central opening of the required shape and size of the plaster, which is tacked down on the plaster skin. The amount of material necessary for spreading a plaster of the required thickness need not exceed 12 or 15 grains for each square inch, or about 0.165 Gm. for each square centimeter. Plaster-spreading requires manipulative skill, and practice alone can bring success.

Mammary or breast plasters are always made circular in form, about 8 inches in diameter, with a 1-inch margin; a hole $1\frac{1}{2}$ inches in diameter is cut in the center, and from this point to the outer edge the plaster is slit to admit folding over the breast. Such plasters are preferably spread on chamois skin, which is softer.

Fly-plaster is the name frequently applied to cantharides or blistering cerate when the same has been spread upon adhesive plaster ready for use. The spreading of the cerate is done in the manner already outlined for regular plaster-masses, except that heat is unnecessary, since the cerate is sufficiently soft to permit of being spread by simple pressure of a spatula; in cold weather the spatula may be slightly warmed with advantage. The amount of blistering cerate necessary for a given space should not exceed 10 or 12 grains for each square inch, or about 0.120 Gm. for each square centimeter. As

fly-plasters are not intended for prolonged application, ordinary muslin or adhesive plaster will answer on which to spread the cerate, the latter material being preferable on account of the adhesive edges, which serve to keep the plaster from slipping. A piece of tarletan, a trifle larger than the surface of the cerate, should be firmly pressed over the same, which, while not interfering with the blistering action of the cantharides, protects the skin from being much soiled, and prevents any of the cerate from getting under the skin if the blistered surface should be lacerated by sudden removal of the plaster.

Porous plasters, which have become very popular, differ from ordinary spread plasters in having numerous small holes punched through them, rendering them more comfortable for prolonged application, by allowing exhalations of the skin to pass off freely. They are prepared on an extensive scale by special machinery.

European dermatologists some years ago introduced a class of preparations known as *plaster-mulls*, which are intermediate in consistence between plasters and cerates. These plaster-mulls, sometimes also called salve-mulls, are especially indicated in cases in which prolonged application is necessary, since, owing to the porous character of the mull or gauze employed, they permit ready evaporation, and thus prevent maceration of the epidermis, which is likely to occur in the case of more occlusive dressings. The vehicle for these plaster-mulls is usually a mixture of suet and lard, containing 70 to 90 per cent. of the former, which is easily spread when heated, but does not melt nor run when applied to the body. As medicating agents, ichthyol, salicylic acid, mercury, and similar substances are employed in various proportions. The general mode of preparation is about as follows: a piece of mull or gauze is spread on a piece of parchment paper which has been previously moistened and pressed; the medicated mass, having been melted, is spread over the gauze by means of a broad brush when upon the point of congealing. The surface is afterward made smooth with a spatula dipped in warm water, and after having lain in a cool place for a few hours the parchment paper is removed. Very similar to plaster mulls are the *collemplastra*, introduced from Germany, in which the vehicle intended for medication is composed of caoutchouc, pine resin, rosin-oil, Venice turpentine, copaiba balsam, and yellow wax, made into a semifluid uniform mixture with the aid of ether. After the vehicle has been medicated as desired and spread on the proper material, the ether is allowed to evaporate, and the surface, as in the case of plaster mulls, is then covered with gauze.

EMPLASTRUM ADHÆSIVUM, *U. S., P. G.*—Adhesive Plaster.

Emplastrum Resinæ, Br. (U. S., 1890).—*Resin plaster*, E.; *Emplâtre adhésif, Emplâtre résineux*, Fr.; *Heftpflaster*, G.; *Empiastro adesivo*, It.

Preparation.—Rubber, 20 Gm.; petrolatum, 20 Gm.; lead plaster, 960 Gm. Melt the rubber at a temperature not exceeding 150° C. (302° F.); add the petrolatum, and continue the heat until the rubber is dissolved. Add the lead plaster to the hot mixture; continue the heat until it becomes liquid, then let it cool, and stir until it stiffens.—U. S.

To make 25 ounces of adhesive plaster will require ½ ounce each of rubber and petrolatum, and 24 ounces of lead plaster.

The formula for adhesive plaster has been materially changed, the yellow wax and rosin formerly used having been replaced by rubber and petrolatum, whereby the adhesive properties of the plaster are increased, and also the tendency to become hard and brittle overcome.

Adhesive plaster of the British Pharmacopœia is composed of hard soap 5 parts, rosin 10 parts, and lead plaster 80 parts, each melted separately at as low a temperature as possible, and then mixed.

The German Pharmacopœia directs that 40 parts of lead plaster, freed from water by heating on a water-bath, shall be melted together with 2½ parts each of hard and liquid paraffin, to which mixture are then added 35 parts of rosin and 10 parts of dammar. While still warm the mass is added to a solution of 10 parts of caoutchouc in 75 parts of petroleum benzin. The mixture is finally heated on a water-bath and constantly stirred until the benzin has all evaporated. This process, while yielding a satisfactory product, requires great care on account of the ready inflammability of the benzin vapor, and contact with flame must be avoided.

The present official adhesive plaster, also known as sticking plaster, when spread upon muslin resembles the commercial rubber adhesive plaster. The latter is now frequently manufactured in combination with zinc oxide, and sold as zinc-oxide adhesive plaster, for the purpose of avoiding the irritation usually caused by plain rubber plaster.

Uses.—Adhesive plaster may be employed for the purpose of holding surgical dressings in place. It has practically been replaced by the unofficial rubber plaster, which is much more efficient, although somewhat more irritating. It is also used for the immobilization of parts, such as the chest in acute pleurisy or fracture of the ribs.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO, *Br.*—Ammoniac Plaster with Mercury.

Ammoniacum and mercury plaster, E.; *Emplâtre de gomme ammoniaque mercuriel*, Fr.; *Quecksilberhaltiges Ammoniakpflaster*, G.

Preparation.—Take of ammoniacum, 12 ounces; mercury, 3 ounces; olive oil, 56 grains; sublimed sulphur, 8 grains. Heat the oil, and add the sulphur to it gradually, stirring till they unite. With the mixture triturate the mercury until globules are no longer visible; add the ammoniacum, previously purified by boiling with successive portions of water, passing the resulting emulsion through a hair-sieve, and, after mixing, evaporating the emulsion to a suitable consistence.—Br.

Ammoniac plaster with mercury has been dropped from the U. S. Pharmacopœia.

Action and Uses.—This plaster possesses the combined alterative and irritant properties of mercury and ammoniac, and may be employed in the treatment of enlarged glands, enlarged joints, and for other swellings dependent upon syphilitic infection. If applied too long or over too large an area it may, in susceptible persons, produce ptyalism.

EMPLASTRUM BELLADONNÆ, *U. S., Br.*—Belladonna Plaster.

Emplâtre de belladone, Fr.; *Belladonnapflaster*, G.; *Emplasto de belladonna*, Sp.

Preparation.—Extract of belladonna leaves, 300 Gm.; adhesive plaster, 700 Gm.; to make 1000 Gm. Melt the adhesive plaster on a water-bath; then add the extract of belladonna, and continue the heat, stirring constantly, until a homogeneous mass results. —U. S.

Belladonna plaster may be conveniently prepared of official strength by incorporating $1\frac{1}{2}$ avoirdupois ounces of extract of belladonna leaves with $3\frac{1}{2}$ avoirdupois ounces of adhesive plaster; to insure a perfectly smooth plaster it may be necessary to soften the extract with a small quantity of water if it appears to have become tough.

Take of liquid extract of belladonna, 4 fluidounces; resin plaster, 5 ounces. Evaporate the liquid extract of belladonna on a water-bath until it is reduced in weight to 1 ounce; add the resin plaster, previously melted, and mix. This plaster contains 0.5 per cent. of the alkaloids of belladonna root.—Br.

The two plasters differ in composition as well as in appearance, the former being of a dark-green and the latter of a brown color.

The U. S. P. plaster, if made from standardized extract of belladonna leaves, will contain 0.42 per cent. of mydriatic alkaloids, and the official requirement is for not less than 0.38 and not more than 0.42 per cent. when assayed by the method given below. While the Pharmacopœia does not give a process for the preparation of machine-spread belladonna plasters made with a rubber base, it demands that all such plasters shall conform to the official alkaloidal standard when assayed by the same method.

Assay of Belladonna Plaster (Rubber Base).—Belladonna plaster, spread upon cloth, 10 Gm.; chloroform, ammonia-water, alcohol, distilled water, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin test-solution, each a sufficient quantity. Into a suitable beaker containing 50 Cc. of chloroform and 3 Cc. of ammonia-water introduce the belladonna plaster cut into strips. Stir until the plaster is entirely removed from the cloth; then pour off the chloroform into another beaker, wash the cloth with 25 Cc. of chloroform and 1 Cc. of ammonia-water carefully, and add the washings to the chloroformic solution first obtained. If necessary, repeat the washing

with 25 Cc. of chloroform, and add this also to the chloroformic solutions. Then dry the cloth at a low temperature; cool and weigh it, and subtract its weight from the original weight of the plaster. To the chloroformic solution add four-fifths of its volume of alcohol, stir gently, and allow the liquid to stand until all of the rubber has separated in a compact mass. Then pour off the supernatant liquid into a separator of 250 Cc. capacity, and having prepared a solution of sulphuric acid by diluting 40 Cc. of normal sulphuric acid with 60 Cc. of distilled water, add 20 Cc. of the solution to the separator, and agitate for 2 minutes, rotating gently. Draw off the chloroformic solution into another separator, shake this with 10 Cc. of the sulphuric acid solution, and add the acid solution to that in the first separator. Repeat until the acid washings cease to give a reaction with mercuric-potassium-iodide test-solution; combine the acid liquids, and having rendered this solution alkaline with ammonia-water, wash out the alkaloids with three successive portions of 25, 15, and 10 Cc. of chloroform. Collect these in a flask and distil off all the chloroform with the aid of a water-bath. To the alkaloidal residue add a slight excess of tenth-normal sulphuric acid, noting the quantity used, then add 10 drops of chloroform and, after rotating, evaporate the latter by means of a water-bath. Then add 5 drops of a hematoxylin test-solution and, rotating, titrate the excess of acid with fiftieth-normal potassium-hydroxide solution. Divide the number of cubic centimeters of fiftieth-normal potassium-hydroxide solution used by 5, subtract the quotient from the number of cubic centimeters of tenth-normal sulphuric acid first added, and divide the difference by the number of grammes of belladonna plaster separated from the cloth, multiply the quotient by 0.0287, and this product by 100, which will give the percentage of mydriatic alkaloids in the belladonna plaster.—U. S.

Action and Uses.—The action of this plaster is fully described under BELLADONNA (which see). It is frequently applied for the relief of rheumatism and neuralgic pains, and serves also as a useful application in the early stages of acute inflammatory conditions, especially when occurring in glands, as in the mammæ or testicles. It is also useful when applied over the heart to relieve cardiac palpitation.

EMPLASTRUM CALEFACIENS, *Br.*—Warming Plaster.

Emplastrum picis cantharidatum, U. S. 1890. *Cantharidal pitch plaster*, E.; *Emplâtre de poix cantharide*, Fr.; *Pechpflaster mit Canthariden*, G.

Preparation.—Cantharides, in coarse powder, 4 ounces; yellow wax, 4 ounces; resin, 4 ounces; resin plaster, 3½ pounds; soap plaster, 2 pounds; distilled water, boiling, 1 pint. Infuse the cantharides in the distilled water for 6 hours; squeeze strongly through calico; evaporate the expressed liquid on a water-bath till reduced to one-third; add the other ingredients; melt on a water-bath; stir until the ingredients are thoroughly mixed.—Br.

The above formula appears unnecessarily complicated, and an equally efficient plaster can be made by following the directions of the U. S. P. of 1890, which were as follows: Melt 80 Gm. of cerate of cantharides on a boiling water-bath and continue the heat for 15 minutes; strain through close muslin, so that the cantharides will be retained. To the strained liquid add sufficient Burgundy pitch to make the whole weigh 1000 Gm. and render the mixture homogeneous by stirring; then remove the heat and stir until the mass thickens. The addition of 65 Gm. of hot water, or olive oil, in place of a like weight of the pitch, will improve the product materially.

Uses.—Warming plaster may be applied as a counterirritant in the treatment of chronic joint-affections, in cases of chronic bronchitis, pleurisy, and other pectoral affections, and in lumbago. Its application should not be continued very long, as it may produce vesication.

EMPLASTRUM CAPSICI, *U. S.*—Capsicum Plaster.

Sparadrapum capsici.—Sparadrap de capsique, Fr.; *Capsicumpflaster*, G.

Preparation.—Oleoresin of capsicum, 0.25 Gm.; adhesive plaster, spread on fabric, a sufficient quantity.

Apply the oleoresin of capsicum by means of a brush, so as to form a thin coating over an area 15 Cm. square, leaving a margin around the sides.—U. S.

4 grains of oleoresin of capsicum will suffice to cover 4 inches square of adhesive plaster.

Uses.—Capsicum plaster is stimulant and rubefacient, and has been used in the treatment of neuralgia, muscular rheumatism, and colic.

EMPLASTRUM CERUSSÆ, *P. G.*—White Lead Plaster.

Emplastrum plumbi carbonatis, Emplastrum album coctum. Plaster of lead carbonate, E.; *Emplâtre de céruse, Emplâtre blanc cuit,* Fr.; *Bleiweisspflaster,* G.

Preparation.—Lead carbonate, in very fine powder, 7 parts; olive oil, 2 parts; lead plaster, 12 parts. Rub the lead carbonate into a smooth mixture with the olive oil, and add to the lead plaster previously melted. Boil the mixture over a direct fire, with constant stirring and occasional addition of hot water, until a perfect plaster-mass results. —P. G.

The plaster if carefully made should be free from dark color. A similar preparation, containing some wax and powdered orris root, is known as *Mahy's plaster.*

Uses.—White lead plaster may be employed as a soothing application to superficial burns and other localized inflammatory conditions.

EMPLASTRUM FUSCUM CAMPHORATUM, *P. G.*—Camphorated Brown Plaster.

Emplastrum matris camphoratum. Camphorated mother plaster, E.; *Mutterpflaster,* G.

Preparation.—Take of red oxide of lead, 300 Gm.; olive oil, 600 Gm.; yellow wax, 150 Gm.; camphor, 10 Gm. Triturate the red oxide of lead with a portion of the oil in a capacious copper kettle until a smooth paste results. Then add the remainder of the oil, excepting a small quantity required for trituration with the camphor, and boil the whole over a naked fire, with constant stirring, until gas bubbles rise, or until the red color of the mixture begins to turn brown. Then moderate the heat, but continue the stirring until the mixture has acquired a dark-brown color, and from time to time allow some drops of it to fall into cold water to test its consistence. When this is satisfactory, remove the vessel from the fire, add the wax in small pieces, and finally the camphor, previously rubbed to a smooth paste with a little olive oil. Mix thoroughly, allow the mixture to become somewhat cool, and while it is still warm, pour the plaster into paper-moulds previously coated with mucilage containing about 5 per cent. of glycerin, and dried.

The formula and directions of the German Pharmacopœia and National Formulary are practically identical.

Uses.—Camphorated brown plaster has been employed in the treatment of mastitis. It may also be used for the same purposes as lead plaster, but is probably somewhat more stimulating.

EMPLASTRUM HYDRARGYRI, *U. S., Br., P. G.*—Mercurial Plaster.

Emplastrum mercuriale.—Emplâtre mercuriel, Fr.; *Quecksilberpflaster,* G.; *Empiastro mercurial,* It.

Preparation.—Mercury, 30 Gm.; oleate of mercury, 1 Gm.; hydrous wool-fat, 10 Gm.; lead plaster, 59 Gm.; to make 100 Gm. Triturate the mercury with the oleate of mercury in a tared capsule until the former is thoroughly divided, then add the hydrous wool-fat, and continue the trituration until globules of mercury are no longer visible. Add the mixture to the lead plaster, which has previously been melted in a tared dish with the aid of a water-bath, and incorporate thoroughly, adding, if necessary, sufficient lead plaster to make the product weigh 100 Gm.—U. S.

The extinguishment of mercury by means of mercuric oleate presents no difficulty, and a smooth, uniform plaster can be readily obtained.

To make 4 avoirdupois ounces of mercurial plaster, triturate 525 grains of mercury with 18 grains of mercuric oleate, and after the globules have all been extinguished, incorporate with 175 grains of hydrous wool-fat and 1032 grains of lead plaster previously melted.

The Br. P. directs that 3 ounces of mercury be extinguished by trituration with a previously blended mixture of 8 grains of sulphur and 56 grains of olive oil. When

globules are no longer visible, 6 ounces of lead plaster, previously liquefied, are added, and the whole thoroughly mixed.

The P. G. directs that 6 parts of mercury shall be triturated with 3 parts of anhydrous wool-fat until uniformly mixed, and then added to 18 parts of lead plaster and 3 parts of yellow wax previously melted together.

The French Codex gives a formula for *Emplastrum de Vigo cum mercurio*, which is occasionally used here. It is made by fusing together: lead plaster, 200 parts; yellow wax and resin, each, 10 parts; add thereto the following powders: olibanum, ammoniac, bdellium, and myrrh, of each, 3 parts; and saffron, 2 parts; also 60 parts of mercury extinguished by 10 parts of turpentine; and finally 30 parts of liquid storax and 1 part of oil of lavender.

Uses.—The use of mercury plaster is fully discussed under HYDRARGYRUM (which see).

EMPLASTRUM LITHARGYRI COMPOSITUM, *P. G.*—Compound Lead Plaster.

Emplastrum galbani compositum. Emplastrum diachylum gummatum, Fr. Cod.; *Compound galbanum plaster, Compound diachylon plaster*, E.; *Emplâtre diachylon gommé*, Fr.; *Gummipflaster, Mutterharzpflaster, Zugpflaster*, G.

Preparation.—Melt together on a water-bath 24 parts of lead plaster and 3 parts of yellow wax; to the partly cooled mass add a mixture of 2 parts each of ammoniac, galbanum, and turpentine, previously melted, with addition of a little water, and strained.—P. G.

It must be borne in mind that the turpentine of the P. G. is not identical with the solid oleoresin known as white turpentine in this country, but is a thick, somewhat viscid fluid containing 70–85 per cent. of resin and 30–15 per cent. of oil of turpentine.

The admixture of gum-resins with lead plaster presents some difficulties; by heating them with about one-third of their weight of water at a moderate temperature, they soften and can then readily be mixed with the turpentine; the mixture, after straining to remove foreign matter, permits of uniform incorporation with the melted wax and lead plaster. The finished product is of tenacious consistence and yellowish color, becoming gradually harder and darker. It is best preserved in small rolls wrapped in paraffined paper.

Uses.—Compound galbanum plaster may be employed as a stimulant application to enlarged glands resulting from scrofulosis. It is said to be efficient also in removing the induration frequently seen around long-standing sinuses.

EMPLASTRUM MENTHOL, *Br.*—Menthol Plaster.

Emplâtre de menthol, Fr.; *Mentholpflaster*, G.

Preparation.—Take of menthol, 1½ ounces; yellow wax, 1 ounce; resin, 7½ ounces. Melt the wax and resin together; when the mixture approaches the temperature of 71.1°–76.7° C. (160°–170° F.) stir in the menthol until dissolved.—Br.

Uses.—This plaster is employed as a counterirritant for the relief of migraine, supra-orbital and other superficial neuralgias.

EMPLASTRUM OPII, *U. S., Br.*—Opium Plaster.

Emplastrum opiatum s. cephalicum s. odontalgicum.—Emplâtre d'opium, Emplâtre céphalique (temporal, adontalgique, calmant), Fr.; *Opiumpflaster, Hauptpflaster*, G.

Preparation.—Extract of opium, 6 Gm.; water, 8 Cc.; adhesive plaster, 90 Gm. Rub the extract of opium with the water until it is uniformly soft; add it to the adhesive plaster, which has been previously melted in a tared dish on a water-bath, and continue the heat with constant stirring until the product weighs 100 Gm.—U. S.

The British Pharmacopœia directs that very finely powdered opium, 1 ounce, be gradually stirred into 9 ounces of melted rosin plaster.

Besides the change in composition of opium plaster in the present official formula (replacement of Burgundy pitch and lead plaster by adhesive plaster), the strength is slightly increased on account of the change in the morphine standard of the extract of

opium. The present opium plaster contains 1.20 per cent. of morphine, while the plaster of 1890 contained 1.08 per cent.

Uses.—The local application of opium is fully described under this drug (which see).

EMPLASTRUM PICIS, *Br.*—Pitch Plaster.

Emplastrum picatum, Fr. Cod.; *Emplastrum picis Burgundicæ*, U. S. 1890.—*Burgundy pitch plaster*, E.; *Emplâtre de poix de Bourgogne*, Fr.; *Burgunder Pechpflaster*, G.

Preparation.—Burgundy pitch, 26 ounces; frankincense, 13 ounces; resin, 4½ ounces; yellow wax, 4½ ounces; olive oil, 2 ounces; distilled water, 2 fluidounces. Add the olive oil and the water to the frankincense, Burgundy pitch, resin, and beeswax, previously melted together; evaporate with constant stirring to a proper consistence.—Br.

The French Codex directs that 1 part of yellow wax and 3 parts of Burgundy pitch be melted together.

The Burgundy pitch plaster of the U. S. P. of 1890 was very similar to the plaster of the Br. P., being composed of Burgundy pitch 80 parts, yellow wax 15 parts, and olive oil 5 parts, melted together and stirred until the mass thickens on cooling.

Uses.—This plaster is a mild counter-irritant, but is mainly applied for the support which it gives.

EMPLASTRUM PLUMBI, *U. S., Br.*—Lead Plaster.

Emplastrum lithargyri (*simplex*), P. G.; *Emplastrum simplex*, Fr. Cod.; *Emplastrum diachylon simplex.—Diachylon plaster, Litharge plaster*, E.; *Emplâtre simple, Emplâtre de plomb* (*de litharge*), Fr.; *Bleipflaster, Diachylonpflaster*, G.; *Empiastro diachilon*, It.; *Emplasto de la Vireina*, Sp.

Preparation.—Soap, dried and in coarse powder, 100 Gm.; lead acetate, 60 Gm.; water, a sufficient quantity. Dissolve the soap in 350 Cc. of hot water and strain the solution. Dissolve the lead acetate in 250 Cc. of hot water, and at once filter the solution into the warm soap solution, stirring constantly. When the precipitate has subsided decant the liquid, and wash the precipitate thoroughly with hot water. Transfer the mass to a warm slab, kneading it thoroughly to free it from water; finally, roll the plaster into cylindrical forms and wrap them in paraffin paper.—U. S.

If avoirdupois weight is more convenient, 6 ounces of lead acetate may be dissolved in 25 ounces of hot water, and this solution filtered into a previously prepared solution of 10 ounces of soap in 35 ounces of hot water.

The present official lead plaster is identical in composition with that made by the former process, and is whiter in appearance. By wrapping the plaster in paraffin paper darkening of the color is prevented or at least retarded. The yield by the official formula is theoretically 190 Gm. of lead plaster, but in practice some loss occurs, and scarcely more than 165 Gm. will be obtained.

Lead plaster of the Br. P. is made by boiling together gently lead oxide 400 Gm., olive oil 800 Gm., and distilled water 400 Cc., by the aid of a steam-bath; the mixture is kept simmering for 4 or 5 hours, stirring constantly until the product acquires a proper consistence for plaster; more water is added during the process, if necessary.

The French and German pharmacopœias use equal parts of olive oil and lard in place of olive oil alone, which is directed by the British Pharmacopœia. A much greater discrepancy, however, exists in the proportion of the fat to the other ingredients. Calculated for 100 parts of fat, there are ordered of water 100 (Fr. Cod.), 50 (Br.), and 10 (P. G.) parts; of litharge, 50 (Br., Fr. Cod., and P. G.) parts. A much smaller amount is decidedly insufficient, and yields a plaster which is and remains sticky. The litharge should not be less than half of the weight of the fat used, and in view of its variable quality may very properly be increased somewhat beyond that proportion.

The P. G. provides for the removal of all glycerin by subsequent kneading of the plaster with water; the Br. P. allows the glycerin to remain mixed with the plaster, and this accounts for the softer condition of the English article.

The chemical reactions involved in the manufacture of lead plaster from lead oxide

and olive oil are clearly the same as are noticed whenever a fat is saponified by means of alkali hydroxides or moist metallic oxides; the presence of water is essential for chemical action, although it also aids in keeping down the temperature, and thus prevents decomposition of the fat. In order to demonstrate the formation of lead plaster (lead oleate or lead soap), olive oil may be looked upon as olein or glyceryl trioleate, leaving out of consideration the presence of very small quantities of palmitin; the following equation then will show the reaction: $2C_3H_5(C_{18}H_{33}O_2)_3 + 3PbO + 3H_2O = 3Pb(C_{18}H_{33}O_2)_2 + 2C_3H_5(OH)_3$. The basylous radical C_3H_5 is trivalent, and is known as propenyl or glyceryl; being displaced from its combination with oleic acid by the lead, it readily unites with the oxygen and hydrogen present to form the alcohol glycerin or propenyltrihydroxide, $C_3H_5(OH)_3$.

Chemically, lead plaster is a mixture of lead oleate and palmitate, containing also stearate if lard has been used in its preparation.

Uses.—Lead plaster is a protective and discutient. It is sometimes used as an application to leg ulcers, and has been employed for the prevention of bedsores and other ulcers resulting from the application of surgical apparatus. If continually employed over a larger area for a long period of time, it may produce chronic lead-poisoning.

EMPLASTRUM PLUMBI IODIDI, *Br.*—Lead Iodide Plaster.

Emplâtre d'iodure de plomb, Fr.; *Jodbleipflaster*, G.

Preparation.—The directions of the British Pharmacopœia for making this plaster are to add 2 ounces of finely powdered lead iodide to a mixture of 2 ounces of resin and 16 ounces of lead plaster, previously melted at as low a temperature as possible, and to mix intimately.

The present formula was proposed by A. W. Gerrard (1874), who showed that the plaster, as formerly prepared with soap plaster, contained very little lead iodide, which was nearly all decomposed by the soap.

Uses.—This plaster is employed for promoting the resolution of chronic inflammatory exudates.

EMPLASTRUM SAPONIS, *U. S., Br.*—Soap Plaster.

Emplastrum saponatum, P. G.; *Emplastrum cum sapone*, Fr. Cod.—*Emplâtre de savon*, Fr.; *Seifenpflaster*, G.

Preparation.—Soap, dried and in coarse powder, 10 Gm.; lead plaster, 90 Gm.; water, a sufficient quantity. Rub the soap with water until brought to a semiliquid state; then mix it with the lead plaster, previously melted, and evaporate to the proper consistence.—U. S.

To make 4 avoirdupois ounces of soap plaster would require 175 grains of powdered soap and 1575 grains of lead plaster.

It is important that the soap be used in the form of powder, so as to insure a smooth mixture with water, and that subsequently the water be again expelled by evaporation, otherwise the plaster loses it adhesive properties.

Soap plaster of the British Pharmacopœia contains nearly 50 per cent. more of soap and also a small quantity of resin, the proportions being: soap, 6 ounces; resin, 1 ounce; and lead plaster, 3 ounces, which are melted and mixed.

The proportion of soap directed is 5.6 (Fr. Cod.), 5.8 (P. G.), 10 (U. S.), and 14 (Br.) per cent. The French Codex orders also 4.5 per cent. of white wax, while the German Pharmacopœia uses yellow wax 1.15 and camphor 1.15 per cent. The U. S. P. alone requires the soap to be rubbed up with water; the P. G. orders the soap to be powdered, and mixed with the camphor and one-fifth of its weight of olive oil before it is incorporated with the melted plaster and wax. Soap plaster has a whitish color, and should be nearly free from water, which renders the plaster slippery.

Uses.—Soap plaster is a discutient, and may be employed for the same purposes as Emplastrum Plumbi (which see).

EMULSA.—Emulsions.

Emulsiones, P. G.; *Émulsions*, Fr.; *Emulsionen*, G.; *Emulsiones*, It., Sp.; *Horchatas*, Sp.

The term "emulsion" is used to designate mixtures of liquids insoluble in one another, where one is suspended in the other in the form of minute globules, as fat in milk, and also mixtures in which solid particles of substances are suspended in liquids in which they are insoluble, as in the case of camphor or resin emulsions. Formerly emulsions were included under the general head of mixtures, "Misturæ," but a distinction is now very properly made, so as to restrict the term emulsion to such mixtures mentioned above as have a milk-like appearance, and in which the suspension of the insoluble liquid or solid is more or less permanent. Nature provides types of emulsions in the form of milk, the natural food of all young mammalia, and the milk-like juices of certain plants from which the official and other gum-resins are obtained. Fixed and volatile oils, as well as ethereal liquids and resinous substances, are suitable for exhibition in the form of emulsion, and the suspension in water is accomplished by the use of appropriate excipients, such as acacia, tragacanth, yolk of egg, etc.; many oil-yielding seeds, as well as the natural gum-resins, contain gummy and albuminous matter by means of which the oil and resin can be brought into perfect suspension in water. The theory of emulsification is as follows: The insoluble liquid or solid in a state of minute division is completely surrounded or enveloped by the vehicle consisting of water and excipient, and thus an opaque mixture is produced from which the particles cannot separate by mere force of cohesion; the stability of the emulsion depends to some extent upon the density of the vehicle, and it will be found that the presence of sugar increases the suspending power of gum, while the addition of alcohol or glycerin in the proportion of 1 or 2 fluidounces in a pint, will prevent fermentative changes likely to arise in vegetable solutions if kept on hand for some time.

With the exception of those composed of volatile oils or ethereal liquids, emulsions should always be made in a mortar, either of unglazed Wedgewood or hard porcelain, having a flat bottom, and, in the case of seed or gum-resin emulsions, one of deep shape provided with a hard-wood pestle is to be preferred, in order to avoid injury from the force often necessary in crushing and manipulating the material. For making gum-resin emulsions, the cleanest and best tears should be selected, as the commercial fine powders are unfit for this purpose, partly because they are inferior in quality, and partly because they have been so modified by drying that when triturated with water they form simply an ordinary mixture from which the powder separates rapidly on standing; this change is due to dehydration, whereby the natural association of gum and resin has been broken up and their intimate union destroyed. For seed emulsions, when no other proportions are specified, 1 part of seed is used to 10 parts of water, all dirt and dust being carefully removed, if necessary, by washing with cold water. In both cases the material is crushed into a coarse powder, and, after the addition of a small quantity of water, beaten into a perfectly smooth pasty mass; to this, the remainder of the water is then added in divided portions, triturating the mass thoroughly and keeping it well scraped from the pestle and sides of the mortar, so that a uniform mixture may result, which is finally passed through a previously wetted strainer of flannel or cheesecloth, to remove the inert woody fiber and possible impurities. In making emulsion of lycopodium, it becomes necessary to triturate the seed *dry, with some pressure*, in order to rupture the hard seed-envelope; when the powder changes in color and becomes damp and adhesive from the oil, a little water is added, with which a smooth soft paste can be formed, to be further diluted by the addition of water as directed above. Emulsion of lycopodium *should never be strained*, and, if properly made, will show no particles floating on the surface; the insoluble matter which settles upon standing is readily reincorporated by agitation.

Oil emulsions, which are far more frequently used than those made from seed or gum-resins, require more care in their preparation, as success depends not only on the manipulation, but also on the judicious choice of an excipient. As a general rule, it may be stated that acacia produces the whitest and most stable emulsions, because its perfect and ready solubility in water enables the operator to divide the oil quickly into minute globules, which are at once surrounded by an envelope of the mucilaginous liquid and thus kept from coalescing. The oil-globules of a well-made acacia emulsion, when compared with milk under a magnifying lens, more closely resemble its fat-globules than would be the case if made with other excipients. To insure success, it is essential that definite

proportions of oil, gum, and water be used for making the primary emulsion, which can then be diluted with water as desired. *Not less than one-fourth nor more than one-half* as much acacia as oil should be used, and *not less than one and a half times nor more than twice as much* water as acacia. The mixing of oil, gum, and water should not be effected by the usual method of trituration, which involves pressure of the pestle against the material on the bottom and sides of the mortar, and consequent development of heat, but should be brought about by a rapid light rotary movement of the wrist, communicated to the pestle held loosely in the hand; this motion partakes more of that of an egg-whip, and the oil is thus rapidly broken up into minute globules in the presence of a viscid solution.

As stated before, emulsions of fats and fixed oils are best made in a flat-bottomed mortar, three distinct methods being in use to effect the desired object, namely, a milk-like liquid, miscible with water without separation of oil-globules. By many the method usually recommended in Great Britain is preferred; this consists in making a smooth thick mucilage of granulated acacia and water, and then adding the oil by degrees, stirring assiduously until each portion of oil is emulsified—lastly adding the water for dilution, in divided portions. The two others are sometimes called the "Continental" methods, from the fact that they are used almost exclusively in Continental Europe. They do not direct the previous solution of the gum in water, and adhere strictly to definite proportions. While the so-called "English" method yields satisfactory results in the hands of those accustomed to it, for the inexperienced either of the following methods is much to be preferred:

Place in a mortar one-fourth as much *finely powdered* acacia as the oil to be used (7.5 Gm. of acacia for 30 Cc. of oil, or ʒij for fʒj), then add the oil and triturate well together into a smooth mixture. Now add *all at once*, not gradually, twice as much water as the acacia which has been used (15 Cc. of water for 7.5 Gm. of acacia, or fʒiv for ʒij), and stir rapidly until a perfect emulsion has been formed, which is known by the appearance of a white pasty mass, free from oil particles, and a peculiar crackling noise as the pestle is drawn through the adhesive mixture. This primary emulsion should be well scraped with a spatula from the pestle and sides of the mortar, again stirred, and then the remainder of the water slowly added with constant stirring. Granulated acacia cannot be used in this method, as with so small a quantity of gum it is necessary that it dissolve almost immediately, which will not occur with the granulated variety.

The second of the so-called "Continental" methods directs increased proportions of acacia and water, by which means an equally perfect, and at the same time denser, primary emulsion is obtained. One-half as much granulated acacia as oil is used, and one and a half times as much water as gum, or one-half as much water as oil and gum together; thus, oil 30 Cc. or fʒj, granulated acacia 15 Gm. or ʒiv, and water 22.5 Cc. or fʒvj. Place the acacia in a dry mortar, add the oil and water, and stir briskly until a perfect emulsion results, which dilute with the remaining water, as in the preceding method.

If from any cause the primary emulsion should fail, it will prove a loss of time and labor to endeavor to save it by the addition of gum or water, provided the right proportions were used in the first place; the best plan is to begin over again and observe care in details. Assiduous stirring or shaking is of no avail in trying to save a "cracked" emulsion, which has a pearly appearance in the mortar, and the further addition of gum, while increasing the density of the mixture, does not always remedy the trouble.

The above methods are equally well adapted for liquid oleoresins, such as copaiba, oleoresin of cubeb, etc. If solid fats, camphor, some oleoresins and resinous extracts, as, for instance, extract of Indian cannabis, are to be administered in aqueous liquids, it will be found advantageous to dissolve them in a small quantity of fixed oil (oil of sweet almond or olive oil), and then to emulsify them in the manner directed for these oils. Salol, menthol, thymol, phosphorus, and other substances can likewise conveniently be emulsified after solution in some fixed oil. The emulsification of Peru balsam will materially be facilitated by the addition of a little alcohol or oil of sweet almond, about 10 per cent. of the volume of balsam being sufficient. Whenever double emulsions are ordered, as, for instance, a seed emulsion with that of a fixed oil, better results will be obtained if separate emulsions be made and then mixed; when castor oil is to be mixed with emulsion of almond as a vehicle, the oil should be emulsionized with the requisite quantity of acacia and water, and this primary emulsion then diluted with the almond emulsion, out of which the water necessary for the previous emulsification of the oil has been retained.

Whenever an oil emulsion is made, the rule should be observed never to measure the water in an oily graduate, as otherwise oil particles might subsequently be carried into the mixture, and, failing to be emulsified, eventually rise to the surface. The view held by some authorities, that a good emulsion is capable of emulsifying additional quantities of oil, requires modification, as pointed out by Mr. Gerrard, of England; for, although a perfect fixed-oil emulsion admits of the incorporation of more oil, this latter oil will not undergo emulsification, but simply be mixed intimately, as can be proved by the addition of water, when the newly added oil will separate. A perfect artificial emulsion should have a milk-like appearance and consistence, be miscible with water without separation, should flow readily from the mortar without leaving adhering particles, so that it can be washed with plain water, and, if separation takes place after standing at rest for some time, a cream-like layer should rise to the surface, which can be quickly reincorporated by agitation. Heat is detrimental to the permanence of emulsions and causes separation, so also large quantities of alcohol or saline matter. Substances which have a tendency to absorb water, such as magnesia, should not be mixed with the emulsion, unless previously completely hydrated. All salts should be added in the form of solution, and, together with tinctures and other alcoholic liquids, not until the primary emulsion has been properly diluted.

Emulsions of ether, chloroform, oil of turpentine, and other volatile liquids are best prepared by agitation in a bottle after the manner first suggested by Forbes. The liquid to be emulsionized is poured into a *perfectly dry* bottle and the powdered acacia added, after which the bottle is well shaken so that the acacia may become saturated with the volatile liquid; water is then added and agitation continued until a homogeneous emulsion results, which may further be diluted by the gradual addition of water. Volatile oils and ethereal liquids never form as perfect an emulsion as fixed oils, and separation of the mixture takes place more speedily; if care has been observed, however, in making the mixture, only a dense, creamy layer will rise to the surface, which can be reincorporated by agitation. As a rule, volatile oils and ethers require more gum than fixed oils, and less than 30 grains of powdered acacia should not be used for each fluidrachm; the amount of water first added should always be equal to twice that of the acacia used. Oil of turpentine unites very readily with water and gum, and it is surprising to see how small a quantity of gum will suffice to form a perfect emulsion from which no oil will separate in an uncombined form, only a dense, creamy layer rising, composed of the oil of turpentine, gum, and some water in intimate union; 20 grains of powdered acacia shaken in a bottle with 1 fluidounce of oil of turpentine, and 4 fluidrachms of water then added, will yield a very satisfactory emulsion, which can be kept for days without separating an oily layer. All emulsions of volatile oils are more permanent if made with the aid of some fixed oil previously added to the volatile oil; such emulsions are preferably made in a mortar.

When powdered tragacanth is preferred as an emulsifying agent, it may be used in the proportion of one-tenth or one-eighth of the necessary weight of acacia, and requires from 10 to 20 times its weight of water; it should be thoroughly mixed with the oil in the mortar or bottle, as the case may be, and after the addition of water the mixture should be stirred rapidly or shaken until the primary emulsion has been formed. The division of oil-globules by means of mucilage of tragacanth is much coarser than with acacia, hence tragacanth emulsions are never so white nor seemingly so perfect; but owing to the viscosity and magma-like condition of mucilage of tragacanth the oil-globules, although not finely divided, are kept from reuniting, and thus separation of an oily layer is prevented. Mixtures of tragacanth and acacia are often employed, particularly in the emulsification of cod-liver oil, to obtain greater protection against separation.

Yolk of egg has long been known as a valuable excipient in emulsions, particularly when acids or large proportions of alcoholic liquids are to be added. The yolk from one egg of average size will suffice for 1 fluidounce of a fixed oil or for ½ fluidounce of a volatile oil; in place of the simple yoke, the official glycerite of yolk of egg, also known as glyconin, of which 2½ fluidrachms are necessary for 1 ounce of fixed oil, has been used with decided advantage. In either case the oil should be added in small quantities to the yolk of egg or glyconin, previously rubbed smooth in a mortar, each portion being thoroughly incorporated before another addition is made; if the mixture should become inconveniently thick, a small quantity of water may be introduced, and after all the oil

has been emulsified the prescribed amount of water is added, likewise in divided portions, with constant stirring. The readiness with which yolk of egg unites with fixed oils is due to the fact that it is itself a natural emulsion of an oil and albuminous matter. Some little care is necessary in removing the yolk of egg from the shell, to avoid contamination with the white or albumin, which has a tendency to form clots in the emulsions.

Of other emulsifying agents introduced during the last twenty years, none has been more extensively used, particularly on a large scale by manufacturers, than mucilage of Irish moss. Toward fixed oils the mucilaginous matter of Irish moss behaves somewhat like tragacanth, particularly if the solution of the former be made somewhat thick.

Cod-liver oil emulsions are made more frequently than any other, and in order to disguise the taste use is made of various flavoring agents. The National Formulary suggests the following selection, the quantities named being sufficient for 1000 Cc. (about 33½ fluidounces) of finished emulsion:

Oil of gaultheria, 4 Cc.

Oil of gaultheria, 2 Cc., and oil of sassafras, 2 Cc.

Compound spirit of orange, 1.5 Cc.

Oil of gaultheria, 2 Cc.; oil of bitter almond, 0.25 Cc.; oil of coriander, 0.25 Cc.

Oil of gaultheria, 1.5 Cc.; oil of sassafras, 1.5 Cc.; oil of bitter almond, 0.25 Cc.

Oil of gaultheria, 2.5 Cc.; oil of bitter almond, 2.5 Cc.

Oil of neroli, 1.5 Cc.; oil of bitter almond, 1.5 Cc.; oil of cloves, 0.25 Cc.

EMULSUM AMYGDALÆ, *U. S.*—Emulsion of Almond.

Mistura amygdalæ, Br.; *Emulsio amygdalæ s. amygdalarum, Emulsio simplex.—Milk of almonds, Almond mixture*, E.; *Emulsion simple, Lait d'amandes*, Fr.; *Mandelemulsion, Mandelmilch*, G.

Preparation.—Sweet almond, 60 Gm.; acacia, in fine powder, 10 Gm.; sugar, 30 Gm.; water, a sufficient quantity to make 1000 Cc. Having blanched the almond, add the acacia and sugar, and beat them in a mortar until they are thoroughly mixed. Then rub the mass with 900 Cc. of water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with sufficient water to make the product measure 1000 Cc. Mix the whole thoroughly.—U. S.

To make 1 pint of emulsion of almond will require 460 grains of sweet almonds, 77 grains of acacia, and 230 grains of sugar.

Take of compound powder of almonds, 2½ ounces; distilled water, 20 fluidounces. Rub the powder with a little of the water into a thin paste, then add the remainder of the water, and strain through muslin.—Br.

Uses.—Almond emulsion possesses little medicinal properties other than that of a demulcent. It has been recommended in the treatment of laryngeal, bronchial, intestinal, and urethral irritations, but to be of service should be given in large quantities. The preparation is sometimes employed as a vehicle for more potent or disagreeable remedies. As a nutrient demulcent it should be given in doses of from 4 to 8 fluidounces (120–240 Cc.), several times daily.

Allied Preparation.—Looch Album. *White linctus*, E.; *Potion émulsive gommée, Looch blanc*, Fr.—30 parts of sweet and 2 parts of bitter almonds are blanched, triturated with 20 parts of sugar and 120 parts of water, and the emulsion strained and gradually added, with continued trituration, to a mixture of 10 parts of sugar and ½ part of powdered tragacanth. Finally, add 10 parts of orange-flower water. The finished preparation weighs 150 parts.—Fr. Cod.

EMULSUM ASAFŒTIDÆ, *U. S.*—Emulsion of Asafetida.

Mistura asafœtidæ, Lac asafœtidæ.—Asafetida mixture, Milk of asafetida, E.; *Mixture (Lait) d'asafœtida*, Fr.; *Asafœtidaemulsion, Stinkasantmilch*, G.

Preparation.—Asafetida, in selected tears, 40 Gm.; water, a sufficient quantity to make 1000 Cc. Rub the asafetida, in a mortar, with 900 Cc. of water, at first very

gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with sufficient water to make the product measure 1000 Cc. Mix the whole thoroughly.—U. S.

The formula corresponds to 18.24 grains of asafetida for each fluidounce of water.

A *syrup of asafetida*, of the same strength as the emulsion, may be prepared by triturating 150 grains of selected tears with small quantities of water, decanting the concentrated emulsion until 4 fluidounces are obtained, in which 6 troyounces of sugar are dissolved by agitation. While at first milk-white, it acquires after exposure a pinkish color; the resin, which partially separates on standing, is easily incorporated by agitation. If desired, the asafetida odor may be covered by the addition of a little oil of bitter almond.

Uses.—The uses of this preparation are enumerated under ASAFŒTIDA (which see). The emulsion is quite commonly employed as an enema in the treatment of tympanites. It has also been given by the mouth in the treatment of hysteria. The dose is from 2 to 8 fluidrachms (8–30 Cc.).

EMULSUM CHLOROFORMI, *U. S.*—Emulsion of Chloroform.

Mistura chloroformi, Emulsio chloroformi.—Emulsion de chloroforme, Fr ; *Chloroformemulsion*, G.

Preparation.—Chloroform, 40 Cc.; expressed oil of almond, 60 Cc.; tragacanth, in very fine powder, 10 Gm.; water, a sufficient quantity to make 1000 Cc. Introduce the tragacanth into a perfectly dry bottle of sufficient capacity, add the chloroform, and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about 250 Cc. of water, and incorporate it by a vigorous shaking. Next add the expressed oil of almond in several portions, shaking after each addition, and when the oil has been thoroughly emulsified, add sufficient water, in divided portions, shaking after each addition, until the product measures 1000 Cc.—U. S.

Since the Pharmacopœia directs 4 and 6 per cent. by volume of chloroform and oil of sweet almond, respectively, $\frac{1}{2}$ pint of the emulsion may be conveniently prepared by shaking 154 minims of chloroform with 38 grains of tragacanth, adding 2 ounces of water, then 230 minims of expressed oil of almond, and finally sufficient water to bring the volume of the finished product up to 8 fluidounces.

Uses.—Emulsion of chloroform forms a convenient and permanent preparation for the internal administration of chloroform. It may be given for the treatment of flatulent colic, gastralgia, hysteria, and other nervous conditions. The dose is from 4 to 8 fluidrachms (16–30 Cc.), as needed.

EMULSUM OLEI MORRHUÆ, *U. S.*—Emulsion of Cod-liver Oil.

Emulsion de huile de foie de morue, Fr.; *Leberthranemulsion*, G.

Preparation.—Cod-liver oil, 500 Cc.; acacia, in fine powder, 125 Gm.; syrup, 100 Cc.; oil of gaultheria, 4 Cc.; water, a sufficient quantity to make 1000 Cc. Rub the acacia with the cod-liver oil in a dry mortar until uniformly mixed, then add at once 250 Cc. of water and triturate lightly and rapidly until a thick homogeneous emulsion is produced; to this add the oil of gaultheria and the syrup, with enough water to make the product measure 1000 Cc., and mix thoroughly.

Note.—The oil of gaultheria may be replaced, if desired, by oil of bitter almond or other suitable flavoring.—U. S.

There seems to be no necessity for this formula in the Pharmacopœia, as physicians are apt to vary the proportion of cod-liver oil to be given at one dose, and any one entrusted with the compounding of medicines should be expected to be able to make a perfect emulsion without official directions. The emulsion directed above contains 50 per cent. by volume of cod-liver oil, and if properly made is a thick homogeneous liquid, almost white, and having the peculiar odor and taste of the particular flavoring agent employed. To many persons the flavor of oil of wintergreen is unpleasant, and oil of bitter almond is less objectionable; of the latter oil 2.5 or 3 Cc. will be found sufficient for 1000 Cc. of emulsion. If the emulsion is to be kept on hand for some

time, the addition of 50 or 60 Cc. of alcohol in place of a like quantity of water becomes necessary.

Uses.—For the action and uses of this preparation, see OLEUM MORRHUÆ. The dose of the emulsion is from 1 to 4 drachms (4–16 Cc.).

EMULSUM OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS, *U. S.*—Emulsion of Cod-liver Oil with Hypophosphites.

Emulsion de huile de foie de morue avec les hypophosphites de chaux, de soude et de potasse, Fr.; *Leberthranemulsion mit unterphosphorigsauren Salzen*, G.

Preparation.—Cod-liver oil, 500 Cc.; acacia, in fine powder, 125 Gm.; calcium hypophosphite, 10 Gm.; potassium hypophosphite, 5 Gm.; sodium hypophosphite, 5 Gm.; syrup, 100 Cc.; oil of gaultheria, 4 Cc.; water, a sufficient quantity to make 1000 Cc. Rub the acacia with the cod-liver oil in a dry mortar until uniformly mixed, then add at once 250 Cc. of water and triturate lightly and rapidly until a thick, homogeneous emulsion is produced; add the oil of gaultheria and incorporate thoroughly; dissolve the hypophosphites in 100 Cc. of water, mix the solution with the syrup, and add the liquid gradually to the emulsion with continued trituration. Lastly, add enough water to make the product measure 1000 Cc., and mix thoroughly.

Note.—The oil of gaultheria may be replaced, if desired, by oil of bitter almond or other suitable flavoring.—U. S.

As in the case of the preceding emulsion, there seems to be no occasion for this formula in the Pharmacopœia, except to insure uniformity in the proportion of the hypophosphites to be present, which amounts to about 10 grains of the combined salts in each fluidounce. In physical properties this emulsion is identical with the plain emulsion of cod-liver oil, and, like the latter, it is apt to spoil if kept on hand for some time, unless preserved by means of alcohol.

Uses.—This emulsion combines the medicinal virtues of cod-liver oil with the tonic properties of the hypophosphites. It may be used with benefit in secondary anæmia, scrofulosis, beginning pulmonary tuberculosis, and other debilitated conditions. The dose is from 1 to 4 drachms (4–16 Cc.). (See OLEUM MORRHUÆ; CALCII HYPOPHOSPHIS.)

EMULSUM OLEI TEREBINTHINÆ, *U. S.*—Emulsion of Oil of Turpentine.

Emulsion d'essence de térébenthine, Fr.; *Terpentinölemulsion*, G.

Preparation.—Rectified oil of turpentine, 15 Cc.; expressed oil of almond, 5 Cc.; syrup, 25 Cc.; acacia, in fine powder, 15 Gm.; water, a sufficient quantity to make 100 Cc. Introduce the acacia into a perfectly dry bottle of sufficient capacity, add the rectified oil of turpentine and the expressed oil of almond and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about 25 Cc. of water and incorporate it by vigorous shaking. When the oil has been thoroughly emulsified, add first the syrup, in several portions, shaking after each addition, and then enough water, in divided portions, shaking after each addition, to make the product measure 100 Cc.—U. S.

Emulsion of oil of turpentine oil made by the above formula is a perfectly white liquid which flows readily from a bottle and keeps quite well. The addition of expressed oil of almond insures greater stability, and separation is less likely to occur than if it were omitted. Only the rectified oil of turpentine should be used, as the mixture is intended for internal use. It is questionable whether physicians will use the official emulsion, which contains about 72 minims (4.45 Cc.) of oil of turpentine in each fluidounce, or prefer to vary the proportion to suit individual cases.

Uses.—This emulsion may be employed whenever oil of turpentine is to be given internally. The dose is from 1 to 4 drachms (4–16 Cc.). (See OLEUM TEREBINTHINÆ.)

ENEMATA.

The term "enema" is applied to fluid injected into the rectum, for the purpose of emptying the bowel of gas or feces, or administering drugs which are designed to exercise a local or systemic influence. It is also a means for the giving of nourishment when food cannot be taken by the stomach. An enema is sometimes called a clyster or lavement. An enema for emptying of the bowel is, in many cases, composed of soap and water, or of soapy water with a small amount of turpentine. When a more active enema is desired, the enema asafœtidæ may be used, particularly if tympanites is present; while in cases in which this fails the enema terebinthinæ may be employed. These enemata are prepared as follows: Take of asafetida, 30 grains (2 Gm.); distilled water, 4 fluidounces (120 Cc.). Rub the asafetida in a mortar, and add the water gradually, so as to form an emulsion. This is identical with a mixture of equal parts of water and milk of asafetida. Often pure milk of asafetida may be employed instead of this formula. The ordinary formula for the turpentine enema is: Oil of turpentine, 1 fluidounce (30 Cc.); mucilage of starch, 15 fluidounces (450 Cc.); but the quantity of the turpentine must vary with the irritability of the patient's rectum and the needs of the case. Great care should be exercised that the turpentine is well mixed with the starch, and it is advantageous often to add a little soap and water.

When an active purgative enema is desired, an ounce of magnesium sulphate may be added to 1 pint of warm water; and if it is desirable to increase the activity of this mixture half an ounce of glycerin may be added to it.

When pain is to be relieved, from 30 minims to 2 fluidrachms (2–8 Cc.) of deodorized tincture of opium may be placed in 4 ounces (120 Gm.) of starch water and injected into the bowel. If very speedy relief of the pain is necessary, ½ grain (0.03 Gm.) of morphine may be used instead of the opium, as it is more rapidly absorbed.

When nutrient enemata are required, the following formulæ may be used, but it is always to be recalled that very little sustenance is absorbed from the rectum even under the most favorable circumstances. Before the injection is given the bowel should be gently washed out with soap and water if any fecal matter is present.

Place in an empty bottle 12 ounces of milk, and add to it an egg which has been beaten till its yolk and white are thoroughly mixed. Shake the bottle to diffuse the egg with the milk, and add the contents of a peptonizing tube, such as is found in the market, or a peptonizing tablet of about 5 grains of pancreatin with 10 grains of sodium bicarbonate. Immerse the bottle in a bowl of water at the temperature of 38.3° C. (101° F.), in order that the peptonizing process may be active. After half an hour the liquid is sufficiently peptonized for use. Not more than 4 ounces should be injected at a time; the remainder should be placed in an ice-box until it is needed. Before this chilled mixture is employed, it should be heated to the temperature of the body, but the degree of heat should not be high enough to destroy the peptonizing ferment. In other instances 3 or 4 ounces of lean meat and 2 or 3 tablespoonfuls of warm water may be rubbed up together, pancreatic extract with sodium bicarbonate added, and this injection may be given at once. Still another nutrient enema consists of from 3 to 5 eggs beaten up with 4 ounces of a 20 per cent. solution of grape-sugar. Here again the peptonizing agent must be added in order that the eggs may be digested, and thereby made ready for absorption by the intestinal wall.

ERGOTA, *U. S., Br.*—Ergot.

Secale cornutum, P. G.; *Secale clavatum, Mater secalis, Clavus secalinus.—Spurred rye, Rye smut, Cockspur rye, Mother of rye*, E.; *Ergot de seigle, Seigle ergoté (noir), Blé cornu*, Fr.; *Mutterkorn, Rogenmutter, Kornmutter, Zapfenkorn, Hungerkorn*, G.; *Spermoedia*, Nor.; *Segata cornuta, Grano speronato*, It.; *Cuernecillo (Tizon) de centeno*, Sp.; *Cravagem (or Esperao) de Centeio*, Port.

The sclerotium of *Claviceps purpurea* (Fries) Tulasne (*Cordiceps p.* Fries; *Sphacelia segetum* Leveille.—Class *Fungi*, Fam. *Hippocreaceæ*), replacing the grain of rye (*Secale cereale* L.—Fam. *Gramineæ*). Ergot should be moderately dried and not

exposed to a damp atmosphere. After being kept for more than one year it is unfit for use. This plant has received various other names from botanists, through mistaken identity, due to its growth upon different grasses, and more especially because of its totally different appearance in different stages of development. Ergot is official in all pharmacopœias.

Origin.—In the first, or *mycelial*, stage of ergot, its filamentous cells (*hyphæ*) ramify through the young grain, their mass constituting the *mycelium*. Innumerable reproductive bodies, called *conidia*, are now formed, and a honey-like liquid (*honey-dew*) is abundantly produced upon the surface of the grain. Though of disagreeable odor, this is sought by certain insects, the conidia being thus distributed and propagation secured. The second, or *sclerotial*, stage is developed by the formation of the *mycelium* into a hard and relatively dry mass, containing a large amount of stored reserve food, and covered by a protecting layer, the whole well calculated to resist decay and the destruction of the vitality of the plant. This is the *sclerotium*, which constitutes the drug. In the third, or *thallus*, stage, this body develops upon its surface small wart-like excrescences containing the apertures of bottle-shaped cavities or conceptacles, the *perithecia:* each one of these conceptacles contains a large number of somewhat fusiform cells or spore-sacs, the *asci*, and each of these contains 8 filiform spores, which are discharged from the aperture of the conceptacle agglutinated in a bundle. The formation of the spores takes place about the time of the flowering of the rye, and when brought in contact with its flowers the spores again develop the mycelium. The spore-producing heads are nourished from the contents of tissues of the sclerotium, which at first becomes loose and spongy from the disappearance of the oil, and finally shrivels and is destroyed.

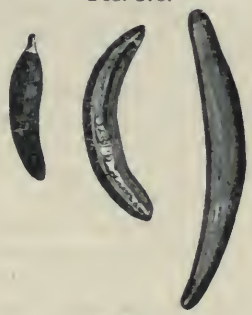
Ergotized rye.

Fig. 173.



Ergot.

Fig. 174.

Ergot: fruiting stage.

Fig. 175.

Longitudinal section of fruiting head, showing conceptacles.

The drying of ergot has to be carefully performed. Its quality is injuriously affected by too great a desiccation, wherefore the official requirement that it be "only moderately dried," whereas incomplete drying subjects it to danger of mouldiness. Its oil is subject to rancidity, and insects are very liable to destroy it. The Pharmacopœia therefore directs that it be preserved in a close vessel and a few drops of chloroform added from time to time, and that it be not used after being kept longer than a year. Various suggestions for its preservation have been made: One is that it be kept over unslaked lime; another, that it be dipped into an ethereal solution of tolu, dried, and preserved in a close vessel; still another, that a small tube filled with potassium sulphate be introduced to the container and a few drops of formaldehyde solution be poured over the potassium

sulphate from time to time. Again, it has been recommended that the oil be removed from it. The Russian Pharmacopœia has recognized an exoleated ergot, but it is very doubtful if this change can be made without detracting from its quality. The German Pharmacopœia has forbidden its being kept in the form of fine powder, as this is liable to quickly deteriorate.

Description.—From 1.5 to 3 Cm. (½ to a little more than 1 In.) long and 3 Mm. (⅛ In.) thick, oblong, tapering toward, but obtuse at both ends, triangular-cylindraceous, the sides unequally grooved; externally purple-black, nearly smooth; internally whitish, with purplish tinge or striæ, the fracture short, not sharp nor snapping; odor peculiar, disagreeable, especially upon trituration with potassium or sodium hydroxide test-solution; taste oily and disagreeable.

The microscopical detection of ergot in flour is often necessary. Genter claims that any amount likely to be injurious can be so detected. It is recognized by the highly refractive properties of the particles, due to their fat, and their greenish-yellow color, and by the deep-violet color and peculiarly notched form of the integument. After being placed upon the slide with water, a boiling heat should be applied, so as to rupture the starch-cells.

The important commercial varieties of ergot are the Spanish, Russian, and German. The first is distinguished by the large size and more blue or violet shade of the purple, the others by a more reddish-purple tint. Although the Spanish looks better and usually commands a higher price, the predominant opinion is that the Russian is more active.

Constituents.*—In the present state of the chemistry of ergot it is impossible to pronounce definitely regarding its active principle. The great diversity of opinion among scientists of recognized ability and the seeming inability of any one to adduce successive evidence of such nature as to force general recognition, are probably due to the low development of the plant itself, and to its consequent inability to produce stable, well-defined, active constituents of definite constitution.

What are at present generally regarded as the more important constituents, most of them physiologically active, are as follows:

Cornutine (Keller, *Schweiz. Wochenschr. f. Chem. u. Pharm.*, 1894).—Alkaloid, readily soluble in ether before crystallization, less so in crystalline form, readily soluble in alcohol and chloroform, insoluble in water and petroleum ether; dilute alcoholic solutions show strong bluish fluorescence; chloroform extracts the alkaloid from slightly acid or neutral aqueous solutions. It is precipitated from acid solutions by alkalies, but is dissolved by an excess of these agents; precipitated by picric acid, iodopotassium iodide, bromine water, tannic acid, potassium ferricyanide, and Mayer's reagent. Concentrated sulphuric acid, when brought in contact with a few milligrammes of the alkaloid on a porcelain surface, gives, on standing a few hours, a violet-blue color. Sulphuric acid plus the alkaloid, with the addition of a minute drop of solution of ferric chloride, gives an orange-red coloration, with a zone of bluish-green around the edge. This last reaction is stated by Keller to be very characteristic. This author rejects the theory of preceding investigators, that ergot contains a number of active principles, and claims that the specific action of this drug is due to a single alkaloid, for which he retains the name of cornutine. At the same time, he denies the purity of the substance experimented with by Kobert, to which the latter investigator assigned the name of cornutine. Keller states that it was undoubtedly due to the presence of this alkaloid (*cornutine*, Keller) in varying proportions that picrosclerotin (Dragendorff), ergotinine (Tanret), and cornutine (Kobert) owed the activity announced by their respective discoverers. Finally, Keller states that cornutine is much more stable than the statements of his predecessors give reason to suppose.

Cornutine (Kobert).—Alkaloid; insoluble in water, soluble in alcohol, ether, and chloroform; readily forms water-soluble salts with acids; physiological action convulsive in nature and distinct from that of the other constituents of the drug. While the author originally considered sphacelinic acid to be the substance exerting the desired specific action upon the uterus, he has lately modified his views to the extent of supposing that this action is contributed to somewhat by cornutine.

Sphacelotoxin (Jacobi, *Arch. Path. u. Pharm.*, vol. 39, p. 85).—A very active substance of acid nature; combines with basic, neutral, or feebly acid substances; decomposed with great ease by chemical agents and probably by age; considered to be quite

* Contributed by Dr. John M. Francis, of Detroit.

stable when combined with ergochrysin or with secaline. The resemblance of the action of sphacelotoxin, as outlined by the author, to that obtained with sphacelinic acid by Kobert, at once suggests the identity or close relationship of these bodies.

Ergochrysin (Jacobi).—Inactive yellow substance.

Secaline ($C_{19}H_{55}N_6O_{14}$, Jacobi).—Crystals; freely soluble in chloroform, sparingly in ether, alcohol, or benzol; practically insoluble in petroleum ether, water, or dilute alkalies; physiologically inactive.

Sphacelinic Acid (Kobert).—Non-nitrogenous acid of resinous nature; insoluble in water and dilute acids, soluble in alcohol, difficultly soluble in ether and chloroform; readily converted by age or chemical manipulation into resinous decomposition-products. Its most marked physiological action consists in the production of gangrene, probably due to blood-stasis through prolonged contraction of the arterioles. The uterine contractions characteristic of ergot, the author ascribes largely to this acid, and his conclusions seem to be confirmed by the experiments of Jacobi with the similar or identical substance which he denominates sphacelotoxin.

Secalintoxin (Sphacelotoxin + Secalin, $C_{18}H_{24}N_2O_2$, Jacobi).—Colorless powder, freely soluble in alcohol, acetic ether, benzol, and chloroform, less soluble in ether, insoluble in petroleum ether. Inasmuch as this body contains sphacelotoxin, it must be possessed of decided activity.

Chrysotoxin ($C_{21}H_{55}N_6O_{10}$, Jacobi).—Possibly a phenolic substance; crystallizes with difficulty; odorless and tasteless; soluble in ether, alcohol, chloroform, and benzol, insoluble in water, petroleum ether, or dilute acids; converted into ergochrysinic acid by alkalies.

Ecboline (Wenzell, 1864; *Jahresb. de Pharm.*, 1872).—Alkaloid. Wenzell demonstrated that it affected the brain and caused contraction of the muscles. Genzer (1870) found this substance to exist in ergot to the extent of 0.16 per cent.

Ergotinic Acid (Kobert, *Arch. f. exp. Path. u. Pharm.*, xviii. p. 316; *Pharm. Centbl.*, 1884).—Not to be confused with ergotinic acid (Wenzell). A nitrogenous glucosidal acid; amorphous, hygroscopic, forming mucilaginous or gummy masses; soluble in water, and in less degree in diluted alcohol; precipitated by concentrated alcohol; decomposed by stronger alkalies, also by acids, with the formation of sugar and a base. The author states that his ergotinic acid is the basis of the sclerotic acid of Dragendorff and Podwissotsky; also that it is the principal medicinal ingredient of the extract generally known as ergotin bonjean, or purified extract of ergot. The experiments of this author also demonstrated that ergotinic acid, when administered internally, exerted no therapeutic action, being in all probability decomposed by the digestive secretions. On the other hand, when injected subcutaneously, its physiological action is quite marked and undesirable, as it exerts a depressant and paralyzant action upon the spinal cord, and to a less degree upon the brain; the blood-pressure is reduced through depression of the motor centers; in sufficient doses, death follows from paralysis of the respiratory center. Kobert also states that this acid has a distinct narcotic action. More important still, the author could not demonstrate that ergotinic acid had the slightest influence upon the gravid uterus, even when injected in quantities sufficient to produce narcosis and paralysis of the spinal cord.

Ergotine (Wenzell).—Constitution assigned by Manassewitz, $C_{50}H_{52}N_2O_3$. Genzer (1870) found this alkaloid in the drug to the extent of 0.04 per cent. Ecboline and ergotine were supposed by Wenzell to exist in ergot in natural combination with ergotinic acid (this ergotinic acid is not to be confounded with the ergotinic acid of Kobert). These are both insoluble in water, soluble in alcohol. Wenzell's experiments with ergotine demonstrated pulse reduction. Some investigators are inclined to identify ecboline (Wenzell) with cornutine (Kobert), and ergotine (Wenzell) with Tanret's ergotinine. Blumberg, on the other hand, insists that ecboline and ergotine (Wenzell) are identical (*Jahresb. de Pharm.*, 1878, p. 51). It is probable that the substances experimented with were too impure to yield results of scientific value.

In addition to the above, the following are more or less active, though their precise nature is doubtful:

Ergotinine (Tanret, according to Villiere, $C_{35}H_{40}N_4O_6$).—Alkaloid; crystalline.

Ergotinine (Tanret, *Jahresb. de Pharm.*, 1875, p. 36).—Alkaloid; amorphous; soluble in alcohol, ether, and chloroform, forming fluorescent solutions; reacts with sul-

phuric acid, forming red to violet to blue color. Kobert's statement that ergotinine (Tanret) is inactive is probably extreme. Like other active principles discovered in ergot, this is probably also an impure product; its characteristic point is its close relationship to ergotine (Wenzell) and picrosclerotine (Dragendorff).

Picrosclerotine.—Alkaloid; stated by Dragendorff to be highly toxic. Its constitution and physiological action have not been thoroughly studied. It seems probable that the substance denominated as above by Dragendorff and Podwissotsky was a very crude product and related in some measure to ergotinine (Tanret) and cornutine (Kobert).

Sclerotic Acid (Dragendorff and Podwissotsky).—3.5 to 4 per cent.; soluble in water, insoluble in strong alcohol, by which it is precipitated from aqueous solutions as a gummy or mucilaginous mass. If Kobert's surmise as to ergotinic acid is correct, the presence of sclerotic acid is sufficient to condemn all aqueous extracts for hypodermic injection.

Scleromucin (Dragendorff and Podwissotsky).—2 to 3 per cent.; similar in physical properties to sclerotic acid. Dragendorff and Podwissotsky ascribed to this and the preceding substance the desirable therapeutic effects of ergot (*Arch. f. exp. Path. u. Pharm.*, 1876, vi. p. 176). Later investigators have asserted this view to be erroneous, and claimed that the two bodies investigated were very impure, and, in fact, that neither of them exerts any of the effects of ergot, but rather that they act as depressants and paralyzants of the spinal cord when injected subcutaneously (see under Cornutine).

The following substances are either inactive or their activity does not contribute materially to the uses of ergot.

Oil.—Estimated variously at from 13 to 35 per cent. Yellowish, fixed, non-drying oil; bland in taste when purified. As separated by some through the use of solvents, this oil is possessed of a slightly bitter or acrid taste. This acridity, as well as the slight physiological activity sometimes reported, is undoubtedly due to small quantities of the active bodies of the drug held in solution. Analysis of the oil gives as its constitution, olein, palmitin, with traces of glycerin-esters of butyric and acetic acids; also traces of lactic and formic acids. As this oil readily undergoes oxidation, which many observers regard as conducive to decomposition of the active bodies, its removal from the drug before storing has been advised.

Mycose (Ergot-sugar), $C_{12}H_{22}O_{11} + 2(H_2O)$.—Crystallizes in rhombic octahedra; melting-point about 100° C. (212° F.); occurs in varying quantity up to 2 per cent.

Choline.—Basic substance giving rise by decomposition to methylamine and trimethylamine; reported by several investigators.

Leucine (Amido-caproic Acid).—Obtained by extracting the drug with warm water, shaking with milk of lime, filtering, and adding alcohol to the filtrate. The filtrate is condensed, and to this is added a solution of basic lead acetate so long as a precipitate forms. After filtration and removal of lead by ammonium carbonate, the filtered solution is evaporated to a syrup. On standing, leucine separates in the form of flakes. Its melting-point is 170° C. (338° F.).

Phytosterin ($C_{26}H_{43}OH$).—Sometimes denominated cholesterin (*Zeit. analyt. Chem.*, 1887, p. 572). Crystallizes in leaflets; melting-point 133° to 145° C. (271.4°–293° F.).

Ergosterin (Tanret, *Jour. de Pharm.*, 1889, xix. p. 225).—Crystals melting at a temperature of 154° C. (309.2° F.).

Sclererythrin.—Red coloring-matter; amorphous powder; insoluble in water and petroleum ether; soluble in alkaline aqueous solutions, in alcohol and sulphuric ether; physiologically inert.

Fusco-sclerotinic Acid, Scleroidin, Sclerocrystalin, Scleroxanthin (Dragendorff and Podwissotsky, *Arch. f. exp. Path. u. Pharm.*, 1876, vi. p. 170).—Identity questionable; coloring-matters, soluble in alkaline solution; presumably inactive.

A *camphor*, claimed to have been isolated by Tanret; identity and constitution doubtful.

Valuation of Ergot.—Recent physiological tests have demonstrated the fact that the alkaloid cornutine (Keller) exhibits about the same vasoconstrictor power as an equivalent amount of the drug itself, and hence the determination of the proportion of such alkaloid present in a sample of ergot or its preparations should be a guide as to their value. Although the alkaloid is supposed to exist in the drug in the free state and is readily soluble in ether, direct treatment with this solvent cannot be employed, since ergot contains a considerable amount of fixed oil. Keller has proposed the following method: 25 Gm. of dry powdered ergot are treated in a percolator with petroleum-ether (benzin) until a few drops of the per-

colate no longer leave a residue upon evaporation. The fixed oil, having thus been removed, the powder is dried and put into a 250 Cc. flask and 125 Cc. of ether added and well shaken. After 10 minutes a mixture of 1 Gm. of calcined magnesia and 20 Cc. of water is added, and the contents of the flask frequently shaken during 30 minutes, which causes the powder to ball together. 100 Cc. of the ethereal liquid are decanted and passed through a pledget of cotton into a separator containing 25 Cc. of 0.5 per cent. hydrochloric acid, the measuring cylinder and cotton being rinsed with a little ether. After thorough agitation and separation, the acid fluid is drawn off into another separator, and the shaking out with acid repeated twice, using 15 and 10 Cc., respectively. The united acid liquids are made alkaline with ammonia water and shaken out with several portions, 50, 25, 20, and 15 Cc., of ether, which is collected in a tared Erlenmeyer flask and distilled to dryness on a water-bath. The residue is treated twice with 5 Cc. of ether, again dried, and weighed. The weight of dry residue multiplied by 5 expresses the percentage of alkaloid present, which in good ergot should not be less than 0.2 per cent.

That the above method of assay is of some value has been shown by the fact that a fluid extract of ergot possessing decided vasoconstrictor virtue lost the same almost entirely when deprived of cornutine by the above method (modified for the fluid preparation); while the removed alkaloid, dissolved in very dilute acid, exhibited the full action on the arterioles.

Pharmaceutical Preparations.—Extract of Ergot, U. S. P.; Fluidextract of Ergot, U. S. P.; Wine of Ergot, U. S. P.

Action and Uses.—Ergot is employed in medicine for two purposes—the arrest of hemorrhage and the contraction of dilated bloodvessels. Of these uses, by far the most important is the arrest of hemorrhage through contraction of muscular tissues. It is important to remember that the drug is of little value in checking hemorrhages from large bloodvessels. Indeed, there is reason to believe that under these circumstances it increases the flow of blood by raising arterial pressure all over the body. When, however, the hemorrhage is from capillary networks, then the ergot, by contracting the minute arterioles, prevents the blood from reaching the capillaries, and so the hemorrhage may be diminished. It finds its most valuable and frequent employment in medicine for the prevention and arrest of post-partum hemorrhage, since under these circumstances it causes powerful contraction of the muscular fibers of the uterus, both by stimulating the cells in the spinal cord which govern this organ, and also by stimulating the muscular fibers of the organ itself.

Ergot ought not to be employed in the first or second stage of labor, since by causing unduly powerful uterine contractions it may cause too rapid delivery of the child, with injury both to the child and to the maternal soft parts. Toward the end of the second stage, or the beginning of the third stage of labor, when the child's head has been born, ergot may be administered, since, by the time it is absorbed, it will produce uterine contraction, aid in the expulsion of the placenta, and diminish the tendency to post-partum hemorrhage. Some obstetricians give it as a routine measure at this stage of labor, but others believe that its administration to every parturient woman at this time is unnecessary, and perhaps unwise in that it may cause retention of tissue or clots which should be expelled from the uterine cavity, by causing undue contraction of the uterine cervix. It is worthy of note that the uterine contractions produced by full doses of ergot are tetanic or tonic in character, and do not permit the periods of relaxation which are so necessary in normal labor for the re-establishment of a circulation in the maternal soft parts and in the placenta.

Ergot has been used in association with the bromides in the treatment of certain forms of vertigo, with asserted success.

Sometimes chronic ergot-poisoning occurs as the result of eating rye bread which is contaminated by ergot. Such varieties of poisoning are exceedingly rare in England and America, but have been met with on the continent of Europe. The chief symptoms consist in the development of dry gangrene in the fingers or toes; or in other cases, in the production of chronic or spastic contraction of the muscles. As ergot is a drug which varies greatly in its physiological activity, it is important to employ a preparation which has been physiologically tested, since much of the ergot upon the market is practically inert (see *Valuation of Ergot*).

When it is necessary to employ ergot hypodermically, it is better to employ a preparation known as "Ergot Aseptic," which contains the physiological activities of active ergot, and is marketed in hermetically sealed aseptic tubes. When this preparation cannot

be obtained, and the case is urgent, fluidextract of ergot may be filtered and administered hypodermically; but under these circumstances the drug is apt to produce an abscess, and it is doubtful whether it is absorbed with sufficient rapidity and in adequate strength to be of material value.

The dose of the extract of ergot is from $\frac{1}{4}$ to 1 grain (0.015–0.06 Gm.); of the fluidextract, $\frac{1}{2}$ to 2 fluidrachms (2–8 Cc.); of the wine of ergot, from a tablespoonful to a wineglassful (16–60 Cc.). The dose of "Ergot Aseptic" is from 15 minims to a fluidrachm (1–4 Cc.).

Allied Drugs.—Innumerable smuts of this and related genera are known, and various of them have been noted as poisonous, but the only other that has found a place in medicine is the following:

Ustilago maydis Leveille (*Uredo m.* DC.—Fam. *Ustilaginaceæ*), *Corn-smut* or *Corn-ergot*, E.; *Ergot de mais*, Fr.; *Maisbrand*, *Beulenbrand*, G.; *Rizon de Maiz*, Sp.—It is a very well-known substance wherever Indian corn is grown, deforming the young ears into huge, misshapen, irregularly lobed or branched bluish-black masses, covered by a delicate, transparent, shining, sometimes whitish integument. Enclosed by this membrane is found a blackish-brown or brownish-black powder, consisting of innumerable spores, which are globular or oval, and when observed under the microscope have a nodular or spiny appearance, from the projections of the exosporium. Corn-smut has a peculiar, rather heavy odor and an unpleasant taste. It should be preserved in a dry place, and should be kept on hand not longer than a year. C. H. Cressler (1881) showed the presence of a volatile base, which is probably identical with *trimethylamine*, and a sugar which crystallizes in needles, is very sweet, and does not reduce Trommer's test-solution—probably *mycose*. Fixed oil, resin, and gummy matter were likewise obtained. Examined by J. H. Hahn (1881) and H. B. Parsons (1882), air-dry corn-smut yielded 9 to 10 per cent. of moisture, 2.5 to 4.2 per cent. of ether extract, and 4 to 5.5 per cent. of ash. Alcohol takes up about 10 per cent. and water about 6.6 per cent. of soluble matter, from the latter of which Parsons obtained 5.5 per cent. of an acid compound which is probably identical with sclerotic acid, and is prepared by the same process.

ERICACEÆ.—The Heath Family.

Genera about 75, species nearly 1500, inclusive of the *Vacciniaceæ*, regarded by many botanists as a distinct family (the Whortleberry Family). This group of plants is calculated to excite the most intense interest. Its relationship to a former flora is indicated by the existence of a large group of monotypical or very small genera. Its anatomical characters are peculiar, exhibiting similarities to other and remotely connected families. The mechanism of the floral structures exhibits the most varied and perfect adaptations to pollination. The flowers, and their relations to the plants producing them, possess a peculiar beauty, and many of them (Kalmia, Azalea, Rhododendron) are showy to the degree of magnificence. Many also are deliciously fragrant. The value of the fruits of the *Vacciniaceæ* (blueberries, huckleberries, cranberries) is great. From a medicinal point of view, the family is interesting because of its poisonous properties and from the large number of domestic remedies which it contributes. A number of species take rather important rank in materia medica (see GAULTHERIA, UVA URSI, CHIMAPHILA). The important poisonous constituent of the family is *andromedotoxin*, which is wholly or practically wanting from the more important drugs. It is an amaroid ($C_{31}H_{51}O_{10}$), occurring in needles melting at 229° C. (444.2° F.), neutral, soluble in 35 parts of water, 9 of alcohol, and quite freely in ether and chloroform. It is not affected by alkaloidal reagents, and gives a fine red color with mineral acids. Bullock obtained it from Kalmia by precipitating the infusion with neutral and basic lead acetates, treating the filtrate with hydrogen sulphide, concentrating, and extracting with chloroform. Pure andromedotoxin has been declared more emetic than emetine or apomorphine, and more toxic than aconitine. Andromedotoxin produces violent vomiting when given in overdose. It at first causes a rise in arterial tension, which may be the result of vomiting. Later it acts as a powerful cardiac depressant, decreasing the force and frequency of the heart's action and lowering blood-pressure.

Ericolin ($C_{34}H_{56}C_{21}$) is a brown amorphous glucoside, partly melting at 100° C. (212° F.), soluble in benzene, yellowish-brown with concentrated sulphuric acid, and giving a characteristic odor with warm dilute acids, due to the freeing of the volatile constituent *ericinol*. It is one of the more important constituents of the medicinal species. *Asebofuscin* ($C_{18}H_{18}O_8$) is a reddish-brown glucoside, insoluble in water, ether, and chloroform, soluble in alcohol, acetic acid, and caustic alkalies, violet with alcoholic hydrochloric acid, and yielding asebogenin. *Asebotin* ($C_{24}H_{28}O_{12}$) is a bitter glucoside, occurring in needles melting at 145.5° C. (294° F.), soluble in alcohol, hot water, and acetic acid, and with difficulty in ether and chloroform, and precipitated by acids from alkaline solution. (*Arbutin* and *Urson* are con-

sidered under UVA URSI.) Tannin is general and abundant, and contributes largely to the value of the more important drugs.

Other Medicinal Species.—*Oxydendrum* (*Sour-wood* or *Sour-tree, Sorrel-tree, Elk-tree*) is the leaves of *O. arboreum* (L.) DC. (*Andromeda a.* L.), a small tree of the southern Allegheny region. They are 12 to 15 Cm. (5 to 6 In.) long and nearly a third as broad, oblong to lanceolate, acute, rather coarsely serrate, smooth, except when young, thickish, almost odorless, and of a very sour taste. They have a high repute among eclectics for their diuretic properties. Sour wood is said to be diuretic and laxative, and is employed by the eclectics for the relief of anasarca, hydrocele, hydrocephalus, and other dropsical effusions. The beginning dose is 2 grains (0.12 Gm.) of an extract, 3 times daily, and gradually increased until 30 grains (2 Gm.) are taken daily. This amount may then be gradually decreased until the beginning dose is arrived at.

Ledum, L.—The two eastern species of this genus have a somewhat interesting physiological and medicinal history. The leaves of *L. Grœnlandicum* Oeder. (*L. latifolium* Ait.), of Greenland and northwestern North America, the *Labrador* or *Continental tea*, or *James' tea*, have been used as a beverage, substituting tea. The shrub is a rather stout, branching evergreen of bog-lands, occasionally reaching a height of 5 or 6 feet. The showy white flowers are borne in dense terminal corymbs and are slenderly pedicelled. The leaves are alternate, almost sessile, 2 to 5 Cm. (1 to 2 In.) long and nearly a third as broad, oblong or oval, obtuse, entire, strongly revolute, smooth above, rusty-tomentose underneath. They contain considerable tannin, with ericolin, and probably some unknown constituent, since they are somewhat narcotic. It is claimed that andromedotoxin is wanting, but the properties of the plant would certainly indicate its presence. The leaves of *L. palustre* L., the *Narrow-leaved Labrador tea, Marsh* or *Swamp tea, Wild rosemary, Marsh cistus, Porsch, Mattenkraut, Ledon, Romarin sauvage*, and known to medicine as *Herba ledi palustris* and *Herba rosmarine silvestris*, are still more active. This plant abounds in swamps of the north-temperate zone. Its leaves are much narrower than those of the last. They have a similar though more aromatic odor, and have been found to contain the same principles as those of the last, together with a peculiar camphor which has been called *Ledum camphor* ($C_{15}H_{26}O$). Ledum produces, when given in full doses, headache, vertigo, restlessness, and a peculiar sort of delirium. It is claimed that it augments the secretion of the saliva, sweat, and urine, and that it causes dilatation of the pupil. It is rarely employed in internal medicine at the present time, but may be tried in 10 grain (0.6 Gm.) doses in the treatment of chronic bronchitis. A decoction is sometimes employed as a vermin exterminator, and the fresh twigs are laid among woollen clothing to protect it from moths.

Poisonous Ericaceæ.—The more important poisonous plants of the family are the following: *Kalmia latifolia* L., the *Mountain, American, Broad-leaved, Wood, Rose*, or *Spurge laurel, Calico bush, Ivy bush, Spoonwood*, or *Clamoun*, very abundant in rocky woods in eastern North America, and the *K. angustifolia* L., the *Narrow-leaved, Dwarf*, or *Sheep laurel, Lambkill* or *Calfkill*, of the same region. The other and rarer species, *K. glauca* Ait. and *K. hirsuta* Walt., doubtless share the properties. The first-named is a hard-wooded, tortuous, stout shrub, ordinarily 6 to 8 feet high, occasionally attaining 2 to 4 times that size in woods. The alternate leaves are shortly and stoutly petioled, 5 to 8 Cm. (2 to 3 In.) long, and rather more than a third as broad, oblong or oval-lanceolate, acute at both ends, entire, very thick and tough, smooth and green, nearly odorless, bitter and astringent. They contain little arbutin, relatively much andromedotoxin, tannin, resin, gum, mannit, etc. Sheep and other animals occasionally eat them with fatal effects. The second-named species grows more in open or exposed situations, especially in hill-pastures, and is usually less than 2 feet in height. Its leaves are opposite or in threes, are smaller, relatively narrower, pale underneath. Its flowers are of a rose-red, those of the former usually pink or whitish. Closely similar, in history and effects, to Kalmia, are several species of *Pieris*, particularly *P. Mariana* (L.) B. et H. (*Andromeda M.* L.), the *Stagger-bush* or *Lambkill*, a native of sandy districts, especially along the coast, of the eastern and southern United States. It is more slender and erect-branched than laurel, nearly as tall, the branches and lower leaf-surfaces black-dotted, the leaves alternate, oblong or oval, smooth above, sparsely hairy underneath, the beautiful, waxy, ovoid-bell-shaped, white or reddish-tinted flowers densely pendulous on the lower sides of the paniculately disposed branches of the preceding season. *Andromeda polifolia* L., the *Wild rosemary, Moorwort*, or *Marsh holy rose*, a low shrub of cranberry bogs of the northern parts of both hemispheres, the leaves linear, strongly revolute, bluish-green above, white underneath, is credited with similar properties.

Rhododendron.—Various species of this genus have records as poisonous plants similar to those of the species just described, and cases of poisoning are recorded from the eating of honey made by bees feeding upon the flowers of a European species. *R. maximum* L., the *Wild rose-bay, Rose laurel, Deer, Horse*, or *Great laurel*, abundant along streams in the eastern United States, has been found to contain andromedotoxin. The recorded symptoms of poisoning by this genus are also characteristic of this constituent. Arbutin, ericolin, ursон, and other constituents of the family also occur in these leaves.

Related Families.—In connection with the *Ericaceæ*, may be mentioned two other small families, long associated with it by systematists as subfamilies. The family *Clethraceæ* is represented by the single genus *Clethra* L., of about 25 or 30 species, of temperate and tropical or subtropical regions. The leaves of *C. arborea* Ait., of tropical America, contain ericolin, and are used somewhat like *Ledum*, under the name *Folha deiro*. Half a dozen other species have been similarly employed, to a slight extent, in their respective homes. Associated with *Chimaphila*, in the family *Pyrolaceæ*, are about a dozen species of *Pyrola* L., several of which have been employed like Chimaphila and Uva ursi. Those which have been examined have also been found to contain the same constituents as those drugs. That most used is *P. rotundifolia* L. (*False, Round*, or *Large-leaved wintergreen, Copper-leaf* or *Dollar-leaf, Waldmangold, Pyrole*), which grows in dry woods throughout the north-temperate zone. It resembles an herb, but its low, short stem is perennial, and its cluster of radical leaves are evergreen. They are 5 to 8 Cm. (2 to 3 In.) long, more or less rotund or broadly oval, rounded at the summit, very abruptly contracted into a long, channelled petiole, very finely crenate, thick and leathery, shining and of a very dark-green, or brownish after drying. The pretty, fragrant, nodding, white flowers are borne upon a scape which is sometimes nearly a foot in length, and are about 1.5 Cm. ($\frac{3}{5}$ In.) broad. *P. elliptica* Nutt. (*Shin-leaf*), of North America, is very similar, but somewhat more slender and smaller in all ways, the leaves about two-thirds as long, and oval or broadly oblong. They are also less thick and leathery, and of a lighter green. The subfamily *Monotropoideæ* contains several interesting genera of saprophytic plants. The curious and beautiful snow-plant, *Pine-drops* or *Albany beech-drops, Pterospora Andromedea* Nutt. (*Monotropa procera* Torr.), the flower-stem of which is commonly seen projecting above the snow in Alpine and high northern regions, is used as a diuretic, anthelmintic, and astringent. *Monotropa uniflora* L., the *Indian pipe* or *Pipe plant, Corpse plant, Ghost flower*, or *American ice-plant*, the drug known as *Fit-* or *Convulsion-root* or *Ova-ova*, abundant in damp woods throughout North America and eastern Asia, is a curious and well-known plant. It is wholly of a ghostly white color, grows in clumps, and is a few inches in height. The stem is thickish, fleshy, bears small erect or appressed scales, the vestiges of leaves, and terminates in a recurved bell-shaped flower about an inch in length and nearly as broad. It contains andromedotoxin, and the root has been used as an antispasmodic and mild hypnotic; *M. Hypopitys* L. resembles it, but bears several smaller and erect flowers. It doubtless contains the same constituent.

ERIGERON.—Fleabane; Colt's-tail.

Canada erigeron or Fleabane, Mare's-tail, Cow's-tail, Horse-weed, Pride-weed, Butter-weed, Blood-stanneh, Seabious, E.; *Besehreikraut, Canadisches Berufkraut*, G.

The dried leaves and flowering tops of *Leptilon Canadense* (L.) Britton (*Erigeron C.* L.—Fam. *Compositæ*).

Origin and Description.—An annual or biennial, more or less rough-hairy herb, native and exceedingly common and abundant as a weed throughout almost the whole of North America, and naturalized in most other countries. It varies in height, when in flower, from a few inches to 6 or 8 feet, the stem being simple up to the flowering branches and densely clothed with alternate, erect leaves, the inflorescence paniculately branched and mostly dense; leaves 1 to 3 or even 4 inches long, the lower oblanceolate and tapering into a short petiole, mostly sparsely serrate-dentate, the upper successively smaller and narrower and more inclined to be acute and entire; heads peduncled, campanulate, about 4 Mm. ($\frac{1}{6}$ In.) long and broad, the involucre with 5 or 6 series of narrow erect scales, the white pistillate rays numerous, shorter than the head and inconspicuous, the disk-flowers tubular, very small, with flattened akenes and a fine bristly pappus, the receptacle very small, naked; odor slightly aromatic, taste astringent, aromatic, somewhat bitter.

The genus was long confused with *Erigeron*, several species of which are also used similarly, though very inferior, and which are occasionally supplied for it. They are readily distinguished by their larger heads with long, showy, spreading rays.

Constituents.—Canada fleabane contains considerable tannin, though its astringent or styptic action is mostly due to its peculiar oil (see Oleum Erigerontis), of which it contains about 0.3 to 0.4 per cent. There are also a little gallic acid and an amaroid.

Action and Uses.—Erigeron is somewhat aromatic, and has been used as a diaphoretic and expectorant. Because of its acrid properties, large doses produce nausea and vomiting. In the form of a decoction ($\frac{1}{2}$ ounce of the root to 1 pint of water) it is given in doses of 1 to 2 tablespoonfuls (16–30 Cc.) in the treatment of dropsy and chronic bronchitis. Its common use in country districts is as an intestinal astringent in diarrhœa.

Allied Drugs.—The *Erigerons* which have been chiefly used are *E. Philadelphicus* L. (*Sweet scabious, Daisy-* or *Philadelphia fleabane*), which is softly hairy, with large, oblanceolate, coarsely serrate-dentate leaves and heads mostly few, 1.5 to 2.5 Cm. ($\frac{3}{5}$ to 1 In.) broad, the very numerous narrow rays light-purple; and *E. annuus* (L.) Persoon (*Aster a.* L.), somewhat like the last, but with few hairs, the leaves more sharply serrate, the heads only about half as large, the rays half as numerous (about 50), white or purplish-white. Both have a composition similar to that of Canada fleabane, but the oil lacks the astringent properties, and the herb is diuretic rather than astringent.

The genus *Leptilon* contains about 20 species, *Erigeron* about 130.

ERIODICTYON, *U. S.*—Eriodictyon; Yerba Santa; Mountain-balm.

Consumptive's weed, Bear's weed, Gum-bush, E.

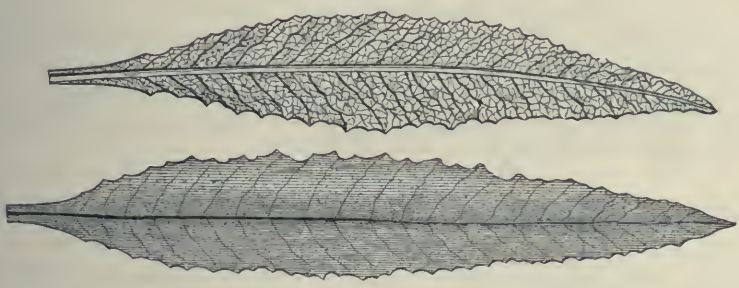
The dried leaves of *Eriodictyon Californicum* (H. et A.) Greene (*Wigandia C.* H. et A.; *E. glutinosum* Benth.—Fam. *Hydrophyllaceæ*).

Eriodictyon is not elsewhere official.

Origin.—A slender, brittle, evergreen, aromatic shrub growing on dry hills of our southwestern States and territories and extending into Mexico, and having pale bluish-purple, bell-shaped or short funnel-shaped, 5-merous flowers. It is notable for the shining coating of gum-resin borne by all its green parts.

Description.—Usually much broken; blade narrowed into a very short and broad petiole, 5 to 12 Cm. (2 to 5 In.) long and rarely exceeding 3 Cm. (1¼ In.) in breadth, oblong-lanceolate, gradually tapering to an acutish point, most irregularly serrate- or crenate-dentate, thick and brittle, or flexible in a damp and warm atmosphere, the margins more or less incurved; upper surface yellowish-green, more or less resinous, smooth, the veins somewhat impressed; lower surface whitish or yellowish-white, with finely and conspicuously reticulate dark veins, densely but very shortly tomentose; many of the hairs glandular; odor somewhat aromatic, strongly balsamic if heated in the closed hand; taste balsamic, sweetish, somewhat tea-like.

Fig. 176.



Eriodictyon leaves: lower and upper surfaces (Nat.).

Constituents.—These leaves contain 9 per cent. of a greenish-yellow, acrid and bitter resin, which forms soluble salts with bases, and, by double decomposition, precipitates quinine from solutions of its salts as salts of a quinine-resin. Eriodictyon also contains an inert resin, a trace of volatile oil, sugar, amorphous brown *ericolin* ($C_{34}H_{56}O_{21}$), and 2.4 per cent. of *eriodictyonic acid* ($C_{14}H_{18}O_5$), which crystallizes in yellow deliquescent plates of sweet-acid taste, soluble in benzol, not precipitated by tannin or most metallic salts, and turning red-black with ferric chloride.

Pharmaceutical Preparations.—Aromatic Elixir of Eriodictyon, N. F.; Fluidextract of Eriodictyon, U. S. P.; Aromatic Syrup of Eriodictyon, N. F.

Action and Uses.—Yerba santa was formerly employed to a limited extent as a bitter tonic and stimulating expectorant. It has been highly recommended in the treatment of asthma and in subacute and chronic inflammations of the respiratory and genito-urinary tracts. Its employment in these conditions, however, is of doubtful efficacy, and at present it is rarely prescribed. In the form of the Syrupus Eriodictyii Aromaticus (N. F.) it is largely employed to disguise the taste of quinine, and is probably the best vehicle we have for this purpose. The drug is usually given in the form of the fluidextract (Extractum Eriodictyi Fluidum, U. S.), in the dose of from ½ to 1 drachm (2–4 Cc.). An extract has also been occasionally employed in doses of from 5 to 15 grains (0.30–1 Gm.).

ERYTHROPHLEUM.—Sassy Bark.

Mancona-bark, Red-water tree bark, E.; *Écorce de Mancone*, Fr.; *Mancona-Rinde*, G.

The dried bark of *Erythrophlœum Guineense* Don (*E. judiciale* Procter; *Fillœa suaveolens* Guill. et Per.—Fam. *Leguminosæ*).

Origin and Description.—From a large, legume-bearing tree of western and central Africa, where it is used as an ordeal (see PHYSOSTIGMA) and as an arrow poison. It occurs in irregular flat or curved pieces, about 6 Mm. ($\frac{1}{4}$ In.) thick; outer surface variously fissured and warty and dark-gray if the corky layer be present, or of a dull red-brown when this is removed; inner surface reddish-brown, striate, hard and heavy, the fracture brittle but somewhat fibrous, exhibiting pale yellow-brown spots; inodorous, but the powder highly sternutatory; taste astringent, somewhat bitter, acrid.

Constituents.—Sassy bark contains erythrophlœine, tannic and gallic acids, gum, and resin. *Erythrophlœine* is a colorless crystalline alkaloid, soluble in water, alcohol, and acetic ether, and almost insoluble in ether and chloroform. When boiled with dilute acids or alkalies it yields erythrophlœic acid and *manconine*, a volatile base resembling pyridine and nicotine.

Action and Uses.—Experiments seem to prove that sassy bark is closely allied to digitalis in its action upon the circulation. It increases the force of the heart action, slows the pulse, and produces a rise in blood-pressure. Respiration is notably decreased and peristaltic action increased. The drug is stated to be astringent, narcotic, and emetic. Erythrophlœine, its active principle, is also said to possess local anæsthetic properties to a greater degree than cocaine, but because of its poisonous character it is not employed for local anæsthesia. Overdoses produce great circulatory depression, respiratory difficulty, nausea and vomiting, and convulsions. Clinically this remedy has been found of little benefit in the treatment of cardiac disease, but it is asserted to be of some value in the treatment of spasmodic asthma. The alkaloid may be given in doses of from $\frac{1}{60}$ to $\frac{1}{30}$ grain (0.001–0.002 Gm.), and an extract prepared from the bark in doses of from $\frac{1}{5}$ to $\frac{1}{3}$ grain (0.012–0.021 Gm.).

Other Species.—The genus *Erythrophlœum*, Don, contains 5 species, all of tropical Africa, and those which have been examined appear to contain constituents acting more or less like erythrophlœine, if they be not even identical.

ESSENTIÆ FRUCTUUM FACTITIÆ.—Artificial Fruit Essences.

Artificial fruit flavors, E.; *Künstliche Fruchtessenzen*, G.

The name artificial fruit essences or flavoring extracts is applied to a class of alcoholic solutions of volatile oils and compound ethers, which are frequently employed for imparting the desired fruit flavor to lozenges, cordials, ices, jellies, etc. They should be used with care, since a very small quantity suffices to give the desired odor and taste. The alcohol used in their preparation should be of not less than 90 per cent. strength and free from foreign odor. The addition of glycerin has been found advantageous in several cases.

The following formulas have been found serviceable, and if the solutions are set aside for some time before using them a better blending of the odors will result.

Whenever alcoholic solution of benzoic, oxalic, succinic, or tartaric acid is directed, it must be understood to refer to a saturated solution of the respective acid, prepared without the aid of heat.

Essence of Apple.—Take of chloroform, 1 fluidrachm; spirit of nitrous ether, 1 fluidrachm; aldehyde, 2 fluidrachms; ethyl acetate (acetic ether), 1 fluidrachm; amyl valerate (apple oil), 10 fluidrachms; alcoholic solution of oxalic acid, 1 fluidrachm; glycerin, 4 fluidrachms; alcohol, 12½ fluidounces.

Essence of Apricot.—Take of chloroform, 1 fluidrachm; ethyl butyrate (butyric ether), 10 fluidrachms; ethyl valerate (valerianic ether), 5 fluidrachms; oil of persicot, 1 fluidrachm; amyl alcohol, 2 fluidrachms; amyl butyrate, 1 fluidrachm; alcoholic solution of tartaric acid, 1 fluidrachm; glycerin, 4 fluidrachms; alcohol, 12½ fluidounces.

Essence of Cherry.—Take of ethyl acetate (acetic ether), 5 fluidrachms; ethyl benzoate (benzoic ether), 5 fluidrachms; oil of persicot, 1 fluidrachm; alcoholic solution of benzoic acid, 1 fluidrachm; glycerin, 3 fluidrachms; alcohol, 12½ fluidounces.

Essence of Currant.—Take of aldehyde, 1 fluidrachm; ethyl acetate (acetic ether), 5 fluidrachms; ethyl benzoate (benzoic ether), 1 fluidrachm; œnanthylic ether, 1 fluidrachm; alcoholic solution of tartaric acid, 5 fluidrachms; alcoholic solution of succinic acid, 1 fluidrachm; alcoholic solution of benzoic acid, 1 fluidrachm; alcohol, 12½ fluidounces.

Essence of Peach.—Take of aldehyde, 2 fluidrachms; ethyl acetate (acetic ether), 5 fluidrachms; ethyl formate (formic ether), 5 fluidrachms; ethyl butyrate (butyric ether), 5 fluidrachms; ethyl valerate (valerianic ether), 5 fluidrachms; oil of persicot, 5 fluidrachms; amyl alcohol, 2 fluidrachms; glycerin, 5 fluidrachms; alcohol, 12½ fluidounces.

Essence of Pear.—Take of ethyl acetate (acetic ether), 5 fluidrachms; amyl acetate (oil of pear), 2 fluidrachms; glycerin, 10 fluidrachms; alcohol, 12½ fluidounces.

Essence of Pineapple.—Take of chloroform, 1 fluidrachm; aldehyde, 1 fluidrachm; amyl butyrate, 10 fluidrachms; ethyl butyrate (butyric ether), 5 fluidrachms; glycerin, 3 fluidrachms; alcohol, 12½ fluidounces.

Essence of Plum.—Take of aldehyde, 5 fluidrachms; ethyl acetate (acetic ether), 5 fluidrachms; ethyl formate (formic ether), 1 fluidrachm; ethyl butyrate (butyric ether), 2 fluidrachms; oil of persicot, 4 fluidrachms; glycerin, 8 fluidrachms; alcohol, 12½ fluidounces.

Essence of Quince.—Take of ethyl pelargonate (œnanthic or pelargonic ether), 1 fluidrachm; alcohol, 19 fluidrachms.

Essence of Raspberry.—Take of spirit of nitrous ether, 1 fluidrachm; aldehyde, 1 fluidrachm; ethyl acetate (acetic ether), 5 fluidrachms; ethyl formate (formic ether), 1 fluidrachm; ethyl butyrate (butyric ether), 1 fluidrachm; oil of wintergreen, 1 fluidrachm; amyl acetate (oil of pear), 1 fluidrachm; amyl butyrate, 1 fluidrachm; alcoholic solution of tartaric acid, 5 fluidrachms; alcoholic solution of succinic acid, 1 fluidrachm; glycerin, 4 fluidrachms; alcohol, 12½ fluidounces.

Essence of Strawberry.—Take of spirit of nitrous ether, 1 fluidrachm; ethyl acetate (acetic ether), 5 fluidrachms; ethyl formate (formic ether), 1 fluidrachm; ethyl butyrate (butyric ether), 5 fluidrachms; oil of wintergreen, 1 fluidrachm; amyl acetate (oil of pear), 3 fluidrachms; amyl butyrate, 2 fluidrachms; glycerin, 2 fluidrachms; alcohol, 12½ fluidounces.

EUCAINA.—Eucaine.

Eucaines are synthetic alkaloidal derivatives of *triacetonamine* and *vinyl-diacetonalkalamine*, and occur commercially respectively as the hydrochlorides of Eucaine A and Eucaine B. Both are used as substitutes for cocaine, and have the advantage over the latter in being less toxic, and the aqueous solutions not suffering decomposition on boiling. For tests of distinction between *α*- and *β*-eucaine and cocaine, see *Proc. Amer. Pharm. Assoc.*, 1904, p. 943.

Eucainæ Hydrochloridum A.—*Eucaine hydrochloride A, Alpha-eucainum, Alpha-eucaine, Eucaine A.—Hydrochloride of benzoyl-n-methyltetramethyl-y-oxypiperidinecarboxylicmethylester.* Formula, $C_{19}H_{27}NO_4.HCl + H_2O$. Molecular weight, 384.80.

Preparation.—Triacetonamine is treated with hydrocyanic acid, the product hydrolyzed by boiling with water, and the benzoyl and methyl groups then introduced by successive treatment with benzoyl chloride and methyl iodide, the resultant product—*benzoyl-n-methyltetramethyl-y-oxypiperidinecarboxylicmethylester*—being the free base *alpha-eucaine*, or *eucaine-A*. This alkaloid crystallized from ether or alcohol presents large glossy colorless prisms which are difficultly soluble in water, soluble in ether, alcohol,

chloroform, and benzene. The alkaloid melts at 104° C. (219.2° F.), and forms crystallizable salts with acids. Eucaine hydrochloride A, the first of these salts introduced commercially in 1896, forms glossy neutral scales or plates, soluble in 10 parts of water at 15° C. (59° F.). The aqueous solutions of the salt are not decomposed on boiling, yield a precipitate of the free base on the addition of the alkali hydroxides and carbonates, and a yellow to orange-red coloration when heated with a few drops of solution of ferric chloride. The salt is distinguished from cocaine hydrochloride, which it resembles in appearance, by its lesser solubility in water, and by yielding a yellow crystalline precipitate when 3 drops of a 5 per cent. aqueous solution of chromic acid are added to 5 Cc. of a 1 per cent. solution of eucaine hydrochloride A. Addition of 3 Cc. of a 10 per cent. aqueous solution of potassium iodide to 5 Cc. of a 1 per cent. solution of eucaine hydrochloride causes an immediate turbidity, which disappears, and after a short time reappears as a crystalline mass. Mercuric chloride causes a white precipitate, and potassium permanganate a violet crystalline precipitate ((Hager).

Tests.—The crystals should be colorless, neutral in reaction, give no discoloration on the addition of sulphuric acid; burn without residue on incineration, and the free base obtained from the aqueous solution by extraction with a volatile solvent after the addition of ammonia should melt at 104° C. (219.2° F.).

Action and Uses.—Full doses of alpha-eucaine produce considerable excitation of the entire central nervous system, and toxic amounts may produce both tonic and clonic convulsions, followed by paralysis and death, the latter resulting from paralysis of the respiratory muscles. If the dose is not a fatal one, the convulsions gradually cease and the paresis slowly disappears. When injected into the circulation, it decreases the rapidity but not the force of the heart action, and has little effect upon the peripheral bloodvessels. Locally applied to mucous membranes or employed by the infiltration-method (see COCA), it causes hyperæmia of the part, while cocaine produces a marked primary contraction of the bloodvessels. Its application is more painful and its action is somewhat slower than that of cocaine, while the anæsthesia produced is equal to that of the latter drug. When dropped in the eye in 2 per cent. solution it may cause irritation of the conjunctiva and roughening of the cornea. It does not paralyze accommodation nor produce mydriasis. Eucaine is considered three and three-fourths less toxic than cocaine, but its great advantage over the latter remedy lies in the fact that it does not cause a primary contraction of the bloodvessels. It may be used as a substitute for cocaine either as a local application or by infiltration in aqueous solutions varying in strength from 0.5 to 10 per cent., but not more than 30 minims (2 Cc.) of a 4 per cent. solution should be used at one time. Eucaine solutions are permanent, and may be boiled without injury for the purpose of sterilization. This drug has not met with favor for intraspinal anæsthesia, as its effects have proved less uniform and lasting than those of cocaine. Poisoning by eucaine should be treated by the use of hot strong coffee, alcohol, strychnine, and digitalis. If the symptoms demand them, ether, ammonia, and nitroglycerin may be employed.

Eucainæ Hydrochloridum B.—*Eucaine hydrochloride B, Beta-eucainum, Beta-eucaine, Eucaine-B, Benzoylvinyldiacetonalkamine hydrochloride.* Formula, $C_{14}H_{21}NO_2$·HCl. Molecular weight, 269.61.

Preparation.—Diacetonamine is treated with paraldehyde, the resulting product reduced with metallic sodium to vinyldiacetonalkamine, and the latter benzoylated by treatment with benzoyl chloride. The free base *benzoylvinyldiacctonalkamine* is dissolved and neutralized with hydrochloric acid and the salt crystallized, forming a white, neutral, crystalline powder, soluble in about 20 parts of water at ordinary temperatures, more soluble in hot water. The 5 per cent. aqueous solution yields no precipitate with mercuric chloride (distinction from eucaine-A); yields amorphous precipitates with the alkali hydroxides and carbonates, the precipitates being soluble in ether. It yields no color-reactions with sulphuric or nitric acid, or with Froehde's reagent. Chromic acid produces a yellow amorphous precipitate soluble in hot water. Bismuth-potassium iodide gives an orange-yellow, picric acid a lemon-yellow, and phosphomolybdic acid a white precipitate.

Action and Uses.—With the exception of the fact that it is less irritating, eucaine-B possesses properties identical with those of eucaine-A. It may be employed in stronger solution, and is the one chiefly used in the eye.

Allied Compounds.—Acoinum.—*Acoine.*—A local anæsthetic and substitute for cocaine, introduced by Trolldenier in 1899. It is a synthetic hydrochloride of *dipara-anisyl-monophenetyl-guanidine.* A large number of oxyphenylguanidines have been prepared by Hesse and Trolldenier, and found to have similar properties to cocaine as local anæsthetics, but have the disadvantage of producing caustic effects in concentrated solutions and in being decomposed on exposure to light. Acoine has been employed in the eye as a local anæsthetic. It produces anæsthesia in about the same length of time as cocaine or eucaine, but does not increase intraocular tension, paralyze accommodation, nor increase the size of the pupil. When instilled into the eye it probably causes more pain than the latter drugs, and it is stated that the newer drug is less satisfactory than the older anæsthetics when congestion or inflammation is present. Acoine is commonly employed in solutions varying in strength from 1 to 300 to 1 to 100 parts of distilled water or normal saline solution. It is stated that subconjunctival injections of it are equally as efficient and less painful than those of any other remedy heretofore employed.

Euphthalmina.—*Euphthalmine. Phenylglycolyl-n-methyl-β-vinyldiacetonalkamine.* Formula, $C_{17}H_{25}NO_3$.—This is a derivative of beta-eucaine, obtained by methylating vinyldiacetonalkamine and treating the resulting product with a very dilute solution of mandelic acid. Two salts of euphthalmine are used, the hydrochloride, $C_{17}H_{25}NO_3.HCl$, and the salicylate, $C_{17}H_{25}NO_3.C_7H_6O_3$. The former is prepared by passing hydrochloric acid gas into an ethereal solution of euphthalmine and recrystallizing the resulting salt from ether. It occurs as a white crystalline powder, readily soluble in water and soluble in 2 parts of alcohol. The salicylate is made by mixing euphthalmine and salicylic acid, in molecular proportions, in ether solution, and recrystallizing the reprecipitated salt. It is readily soluble in water. This alkaloid is employed as an active mydriatic, but it is said to exercise no effect on accommodation. Under its influence the mydriasis begins in from 10 to 20 minutes, is complete in about an hour, and disappears after 5 or 6 hours. A 2 per cent. solution is usually instilled, but a 10 per cent. preparation may be employed. The drug is said to closely resemble atropine in its effects upon the general system.

Holocainæ hydrochloridum. *Holocaine hydrochloride. p-Diethoxyethenyl-diphenyl-amidine hydrochloride.* Formula, $C_6H_4OC_2H_5NH.C(CH_3):N.C_6H_4.OC_2H_5.HCl$. Molecular weight, 332.18. Prepared by the action of molecular proportions of phenacetin and p-phenetidin upon each other in presence of phosphoric chloride, water being eliminated. The resulting free base *holocaine* is recrystallized from alcohol and dissolved and neutralized with hydrochloric acid to form the hydrochloride. Holocaine hydrochloride occurs as a colorless, odorless, neutral, crystalline powder, having a slightly bitter taste, and produces a numbness when applied to the tongue. It is soluble in 40 parts of water, the solution yielding amorphous, changing to crystalline, precipitates with alkali hydroxides and carbonates, a resinous orange-yellow precipitate with chromic acid, and gives the indophenol reaction with chlorinated lime. The salt should be colorless, neutral in reaction, dissolve without color in sulphuric acid, leave no residue on ignition, and the separated free base have the melting-point of 121° C. (249.8° F.). Holocaine has been employed as a substitute for cocaine in ophthalmic practice. Five minims of a 1 per cent. solution when instilled into the eye are usually sufficient to cause anæsthesia in from 1 to 10 minutes. It is claimed by those who have employed it that no scaliness of the cornea results from its use, as is the case with the older remedy.

EUCALYPTOL, *U. S.*—Eucalyptol.

Cajuputol, Cineol, E., G., Fr.; *Terpan; Eucalyptuskampfer,* G.

Formula, $C_{10}H_{18}O$. Molecular weight, 152.98.

A neutral body obtained from the volatile oil of *Eucalyptus globulus* Labillardière.—Fam. *Myrtaceæ,* and from other sources. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light.—U. S.

Origin.—The Pharmacopœia directs eucalyptol to be obtained from the oil of various species of *Eucalyptus,* but does not mention that it may be prepared from other oils, one of which is composed almost wholly of eucalyptol—the oil of santonica, *Artemisia pauciflora* Weber. Eucalyptol is also a constituent of the oils of rosemary and cajuput.

Preparation.—Eucalyptol is prepared from oil of eucalyptus by distillation, and placing the portion going over between 150° and 175° C. (302° and 347° F.) in a freezing mixture, when it crystallizes in long, colorless needles. This is repeated a number of times, always draining the crystals to get rid of the adhering oil. It may also be prepared by the process of Wallach and Brass (1884), by conducting gaseous hydrochloric acid into oil of eucalyptus, pressing out the crystalline hydrochloride formed to free it from the adherent oil, and then decomposing the crystals by treatment with water, which separates the eucalyptol. The latter is then warmed with an alcoholic

solution of potassium hydroxide and distilled with steam. The process of L. R. Scammel also depends upon the formation of a crystalline compound by means of phosphoric acid. Phosphoric acid of specific gravity 1.75–1.785 is added to the oil in slight excess at a temperature not exceeding 15° C. (59° F.), and the eucalyptol phosphate formed pressed out, freed from adherent oil, and then decomposed with water.

Properties.—Eucalyptol is a colorless liquid, having a characteristic aromatic, camphoraceous odor, and a pungent, spicy, and cooling taste. Its specific gravity at 25° C. (77° F.) is 0.925 (U. S.). Cooled to a temperature a few degrees below 0° C. (32° F.) it congeals to a crystalline mass, and liquefies again at —1° C. (30.2° F.); it boils at 176°–177° C. (348.8°–350.6° F.); is optically inactive (distinction from oil of eucalyptus); is miscible in all proportions with alcohol, ether, chloroform, carbon disulphide, turpentine, glacial acetic acid, and fixed and volatile oils. It forms 2 crystalline addition-products with gaseous hydrochloric acid, a crystalline compound with concentrated phosphoric acid of specific gravity 1.75–1.785, and is converted by phosphoric anhydride into *eucalyptene*, $C_{10}H_{16}$, cymene, and *eucalyptolen*. If a solution of eucalyptol be shaken with iodo-potassium iodide, a magma of small green glossy crystals separates. With bromine eucalyptol forms a deep-red crystalline addition-product, $C_{10}H_{18}OBr_2$. It also forms addition-products with α- and β-naphtol.

Tests.—In addition to the above properties eucalyptol should answer the following tests: If a portion of eucalyptol be shaken with an equal volume of sodium hydroxide test-solution, it should not diminish in volume. Its alcoholic solution should be neutral to litmus paper, and should not assume a brownish or violet color on the addition of a drop of ferric chloride test-solution (absence of phenols).—U. S. Mixed with an equal volume of liquid paraffin (paraffinum liquidum) the mixture should remain clear (absence of water).

Action and Uses.—Eucalyptol has been successfully employed as a stimulant expectorant and antiseptic. Internally it may be given in doses of from 5 to 10 minims (0.30–0.60 Cc.), several times daily, in the treatment of chronic pulmonary and bronchial affections. It has also been used as a remedy for the later stages of gonorrhœa. It has been applied as an antiseptic dressing to foul ulcers, and an embrocation containing it may be used in the treatment of sciatica and chronic rheumatism.

EUCALYPTUS, *U. S.*—Eucalyptus Leaves.

Blue gum-tree leaves, Australian fever-tree leaves, E.; *Feuilles d'eucalyptus,* Fr.; *Eukalyptus-Blätter,* G.; *Eucalypto,* Sp.; *Eucalitto,* It.

The dried leaves of *Eucalyptus globulus* Labillardière (Fam. *Myrtaceæ*), collected from the older parts of the tree.

Official in several other pharmacopœias, which specially caution against the use of the ovate leaves, from the younger parts of the tree.

Origin.—From a large forest-tree of Tasmania and southern Australia, often attaining a height of from 200 to 300 feet, and a diameter of from 15 to 25 feet. It has also been very extensively planted in tropical and warm countries, especially in India and California, for its valuable timber, and in malarial regions as a purifier of the soil and atmosphere. Where it grows in sufficient abundance, the soil and the atmosphere become charged with the antiseptic constituents of its fallen leaves and bark, and malaria is unknown. The same result could probably be secured elsewhere by planting it abundantly over a sufficiently extensive area. It was an imperfect understanding of this antimalarial property which suggested the internal use of the leaves as an antiperiodic. As is true of many trees, the youngest growth produces a "junior" leaf, differing markedly from that of the older growth. It is ovate, equilateral, thin and sessile, and is greatly deficient in active constituents. It clothes many young trees completely, and the younger parts of them for some years thereafter. Information is scarce as to the relative quality of the leaves produced from cultivated trees in other countries, but there is good reason to believe that it is deficient in some cases, and the use of the native leaves should be insisted upon. As a matter of fact, our leaves come mostly from California.

Description.—Shortly and stoutly petioled, the petiole twisted, 15 to 30 Cm. (6 to 12 In.) long and 2 to 4 Cm. ($\frac{3}{4}$ to $1\frac{1}{2}$ In.) broad, falcate-lanceolate, rounded or very abruptly contracted at the oblique base, tapering regularly to the acutish or obtusish summit, entire, very thick and coriaceous, smooth, of a dull, pale-green and somewhat glaucous, the venation fine

and inconspicuous, anastomosing near the margin, finely pellucid-punctate; odor aromatic and somewhat camphoraceous; taste camphoraceous, pungent; bitterish.

Leaves which are ovate, equilateral, and only slightly thickened, should be rejected.

FIG. 177.

Eucalyptus globulus Labill.: leaf, about half natural size.

The presence of the objectionable leaves, as of all others used as adulterants of the powder, can be detected by the appearance of their stomata, on a level with the leaf-surface, instead of deeply depressed, as in the genuine. A fine powder should exhibit no fragments of epidermis in which the guard-cells of the stomata can be distinctly seen upon a vertical view, nor any fragments which, not possessing stomata, exhibit wavy epidermal cells upon vertical view.

Constituents (for *volatile constituents*, see OLEUM EUCALYPTI).—The leaves yield tannin, cerylic or an allied alcohol, an acid crystallizable resin, 2 other resins, eucalyptic acid, and about 6 per cent. of volatile oil.

Pharmaceutical Preparations.—ELIXIR OF EUCALYPTUS, N. F.; FLUIDEXTRACT OF EUCALYPTUS, U. S. P.

Action and Uses.—Eucalyptus depends principally upon a volatile oil for its medicinal properties. The local application of the oil causes burning pain and irritation. Taken internally, the drug produces a sense of warmth in the stomach, an increased flow of saliva, and eructation of gas. In ordinary dose it produces slight stimulation, followed by a period of calm. A sense of well-being is experienced, the mind is clear and active, the pulse is increased in frequency, and aphrodisiac effects are noted. Overdose sometimes causes intestinal indigestion, with loose oily stools, fever, great excitement, respiratory difficulty, symptoms of cerebral congestion, and partial palsy of the lower extremities. The drug is eliminated by the lungs, bowels, and kidneys, the urine sometimes having an odor like that of violets after its ingestion. Eucalyptus may be given internally in the treatment of malarial fever, and is especially useful in those cases possessing an idiosyncrasy to quinine. It may also be employed in rheumatic and malarial headache, in migraine and other neuralgic conditions. The remedy has been recommended also in the treatment of subacute and chronic bronchitis, spasmodic asthma, and the later stages of gonorrhœa. As an antiseptic it is said to be superior to carbolic acid, but the drug has never been largely employed as such. A local application containing the oil is valuable in the treatment of chronic skin affections, ulcers, and other conditions in which a stimulating antiseptic is required. The dose of the oil is from 10 to 20 minims (0.6–1.3 Cc.); of the fluid extract, from ½ to 2 fluidrachms (2–8 Cc.).

Other Species and Products (*for other eucalyptus oils, see* OLEUM EUCALYPTI; *for eucalyptus gum, see* KINO; *for eucalyptus honey, see* MEL; *for eucalyptus manna, see* MANNA).—The genus *Eucalyptus* contains in the neighborhood of 150 species, nearly all of Australasia, a few in the East Indies. The products of the genus are invaluable in the countries where they originate. The many volatile oils which have been distilled from other species differ greatly in composition, and this is also true of those leaves which have been analyzed. Those of no other species have come into use, but the barks of several are in use under the name of *Stringy bark*, for their aromatic properties, and for the distillation of their oil, especially those of *E. eugenioides* Sieber (*White stringy bark*), *E. capitellata* Sm. (*Brown s. b.*), *E. macrorhyncha* J. Muell. (*Red s. b.*), *E. piperita* Sm., and *E. punctata* DC. Their content of oil scarcely ever exceeds 0.75 per cent.

EUGENOL, *U. S.*—Eugenol.

Oleum Caryophyllorum, P. G.—*Allylguaiacol, Allylmethylpyrocatechol*, E.; *Eugenol*, Fr., G.

Formula, $C_{10}H_{12}O_2$ or $C_6H_3(OH)(OCH_3).C_3H_5$. Molecular weight, 162.86.

An unsaturated, aromatic phenol obtained from oil of cloves and other sources. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light.—U. S.

Besides being the chief constituent (80–90 per cent.) of oil of cloves, eugenol is also found in the oils of pimento, bay, Ceylon cinnamon, camphor, canella alba, sassafras, and Massoi bark.

Source.—Eugenol is mainly obtained from oil of cloves by the following process: The oil is shaken with an excess of 5 or 10 per cent. of sodium hydroxide solution in a separator and the resulting solution of eugenol sodium drawn off. After washing the aqueous liquid with ether it is decomposed by means of diluted sulphuric acid, and the separated eugenol washed with solution of sodium carbonate to remove adhering acid, and finally distilled with steam or in vacuo.

Properties.—Eugenol is a colorless or pale-yellow, thin liquid, having a strongly aromatic odor of cloves, and a pungent and spicy taste. Exposure to air causes it to become darker and thicker. Its specific gravity at 25° C. (77° F.) is 1.072 to 1.074, and it boils at 251° to 253° C. (483.8°–487.4° F.). Eugenol is optically inactive, and is miscible with alcohol in all proportions; it should be soluble in 2 parts of 70 per cent. alcohol. When 1 part of eugenol is dissolved in 12 parts of sodium hydroxide test-solution previously diluted with 18 parts of water a clear solution should result, which becomes turbid when exposed to the air. A mixture of 1 part of eugenol and 20 parts of hot water should redden litmus-paper very slightly. 5 Cc. of the cold, clear filtrate from this mixture, upon addition of 1 drop of ferric chloride test-solution, should show a transient grayish-green color, but not a blue or violet color (absence of phenol).—U. S. Eugenol is a monatomic phenol, and as such is capable of forming saline compounds with sodium or potassium hydroxide, having the composition $C_6H_3(C_3H_5)(OCH_3)O$—Na or K. It is readily soluble in ether, chloroform, and glacial acetic acid. When boiled with acetic anhydride it is converted into aceto-eugenol, $C_{10}H_{11}(C_2H_3O)O_2$, which melts at 30.5° C. (86.9° F.) and boils at 270° C. (518° F.). 5 Gm. of eugenol shaken with 20 Gm. of 15 per cent. sodium hydroxide solution and 6 Gm. of benzoyl chloride forms benzoyl-eugenol, $C_{10}H_{11}(C_7H_5O)O_2$, which, being insoluble in water, may be washed with the latter and then recrystallized from alcohol in the form of colorless needles, melting at 70.5° C. (158.9° F.). Upon oxidation with potassium permanganate eugenol yields vanillin; it is used for the manufacture of the latter substance.

Action and Uses.—Eugenol may be employed as a substitute for oil of cloves. (See OLEUM CARYOPHYLLI.)

EUONYMUS, *U. S.*—Euonymus.

Euonymi Cortex, Br.; *Cortex euonymi.*—*Wahoo, Spindle-tree, Strawberry-tree, Burning bush, Arrow-wood, Bursting heart*, E.; *Écorce de fusain (de bonnet de prêtre)*, Fr.; *Spillbaumrinde, Spindelbaum, Pfaffenhütchen*, G.

The dried bark of the root of *Euonymus atropurpurea* Jacq. (Fam. *Celastraceæ*).

Origin.—A large shrub or small tree growing abundantly east of the Mississippi and extending westward of it to some extent, especially northward. It inhabits slopes, preferably in the vicinity of streams. It is considerably cultivated as an ornamental shrub, the pendulous, 4-lobed, persistent fruit bursting in the fall to display the scarlet arils of the seeds. Its branchlets are slightly quadrangular, the leaves opposite, petioled, elliptic-ovate, serrate, and pointed; the flowers are dark-purple, in loose cymes of 3 to 6, and appear in June. Both the stem-bark and root-bark are collected, but the use of the latter only is authorized. The root-bark yields a brown extract ("Brown Euonymin"), the stem-bark a greenish one ("Green E.").

Description.—In quilled strips or pieces of very irregular size, usually with a few fine, hair-like roots adhering; bark 1 to 5 Mm. ($\frac{1}{25}$ to $\frac{1}{5}$ In.) thick; outer surface ashy or pale brownish-gray, usually with some small dark patches, shallowly fissured and ridged, with a somewhat scaly and soft friable cork; inner surface whitish or slightly tawny, indistinctly

short-striate; fracture short, whitish, or the inner layer pale brownish in bark which has been long kept; when slowly broken, the ends are held together by fine, somewhat elastic fibers; odor distinct and characteristic, somewhat saponaceous; somewhat gummy in the mouth, the taste sweetish, bitter, somewhat acrid.

The stem-bark, which is in long, tough strips, with a dark-gray or blackish fissured cork, should be rejected.

The greenish-gray powder of the stem-bark contains numerous bast-fibers, that of the root-bark few, and the latter is of a lighter color.

Constituents.—The bark yields euonymin, euonic acid crystallizing in needles, citric, tartaric, and malic acids, fixed oil, 1.3 per cent. of volatile oil (Cassaday), crystalline free fatty acids, yellow and brown resin, an acrid principle, bitter extractive, wax, pectin, and starch. Naylor and Chaplin found *atropurpurin*, which they afterward proved to be *dulcit*, a sweet substance. Cassaday found 1.48 per cent. of euonic acid and resin, and 2.16 per cent. of euonymin and resin. *Euonymin* is an amorphous, odorless, bitter principle, soluble in alcohol, and slightly in water and ether. Meyer and Romm (1885) considered it a crystalline glucoside.

Pharmaceutical Preparations.—Elixir of Euonymus, N. F.; Extract of Euonymus; Fluidextract of Euonymus, U. S. P.

Action and Uses.—Wahoo is said to act as a direct stimulant to the liver, increasing biliary flow. When given in overdose, it irritates the gastro-intestinal tract. It is somewhat uncertain in its action, at times causing severe purgation, at others only acting as a mild laxative. It may be employed as a remedy for mild hepatic torpor in doses of from 3 to 10 grains (0.20–0.60 Gm.). As a laxative, ½ fluidrachm (2 Cc.); as a purge, 2 fluidrachms (8 Cc.) of a fluidextract may be given. Euonymin is occasionally given in doses of from ½ to 1 grain (0.03–0.06 Gm.).

Other Species.—The genus contains about 60 species, widely distributed through the old and new worlds, in both temperate and tropical regions, the greatest number in the East Indies.

E. Europæus L. (*Dog-wood, Prick-wood, Skewer-wood*) is 2.4 to 6 M. (8 to 20 Ft.) high, occasionally cultivated in gardens, has greenish-yellow flowers and pale-red capsules, the arillus being orange-red. All parts of it are emetic and purgative. The fruit, made into an ointment, has been used for the destruction of pediculi. The arillus yields by pressure an orange-colored oil which has a bitter taste. The orange-red coloring-matter, which is quite prevalent in this natural order, seems to deserve careful investigation.

E. Japonica L. (*Tu-chung, Muh-mien*) is used in oriental countries in the treatment of spermatorrhœa. The bark of *E. tingens* Wall. (*Barphali, Sikhi*) is used in India to produce a yellow dye.

EUPATORIUM, *U. S.*—Eupatorium.

Herba eupatorii perfoliati.—Thorough-wort, Thorough-stem, or Thorough-wax, Boneset, Indian sage, Cross-wort, Sweating-herb, E.; *Herbe d'eupatoire perfolies, Herbe à fièvre*, Fr.; *Durchwachsener Wasserdost*, G.; *Eupatorio*, Sp.

The dried leaves and flowering tops of *Eupatorium perfoliatum* L. (*E. connatum* Mx.—Fam. *Compositæ*).

Eupatorium is not elsewhere official.

Origin and Description.—A rather stout, simple-stemmed (except for the inflorescence branching), coarsely gray-hairy, perennial herb, with broad whitish inflorescence, abundant in low, open lands throughout eastern and central North America, its medicinal use derived from the aborigines. The drug loses 75 to 80 per cent. of its weight in drying. Leaves opposite, the 2 united by their broad bases, the uppermost often distinct, those of the inflorescence mostly alternate and greatly reduced; 8 to 15 Cm. (3 to 6 In.) long and 1.5 to 5 Cm. (¾ to 2 In.) broad, tapering regularly from near the base to an acute apex, crenate-serrate, above bright-green or somewhat yellowish-green, rugose and finely bullate; underneath yellowish-gray-green; densely short-hairy and resinous-dotted, the prominent, rounded, crooked, fine veins conspicuously reticulated; flower-heads very numerous, in broad corymbs, the branches rough-hairy; mature involucre campanulate, the imbricated scales lance-oblong, obtusish, green, hairy, the inner longer and with whitish tips and margins; flowers of the head about 10 to 16, tubular, yellowish-white, the pappus in a single row, white, bristly; odor weak, aromatic; taste bitter, astringent, aromatic.

Its connate leaves, with their rugose and grayish-hairy surfaces, distinguish it from all the numerous species similarly used, and which may be supplied for it.

FIG. 178.

Boneset herb (½ Nat.): *a*, flower-head (× 2); *b*, floret (× 3).

Constituents.—Thorough-wort contains a trace of volatile oil, some tannin, resin, yellow coloring-matter, $C_{27}H_{30}O_{17}$, of the nature of a glucosidal tannin, gum, and *eupatorin*, a very bitter glucoside, $C_{35}H_{58}NO_{10}$, soluble in alcohol, ether, chloroform, and boiling water, and insoluble in cold water. The root yields 5 per cent. of inulin. For account of complete proximate analysis of the drug, see *Proc. Amer. Pharm. Assoc.*, 1900, vol. 48, pp. 216–232.

Pharmaceutical Preparation.—FLUIDEXTRACT OF EUPATORIUM, U. S. P.

Action and Uses.—Eupatorium is rarely prescribed by the physician, but is largely employed by the laity. It is a stimulant tonic in small doses, a laxative in large doses, and an emetic or diaphoretic in warm infusion. A hot infusion is most commonly employed for the purpose of aborting beginning colds, early bronchitis, sore throat, and similar acute inflammations. Boneset has also been used in the treatment of influenza, but its efficacy is questionable. Like other simple bitters, it may be employed in atonic dyspepsia, but it has no especial advantage over the others.

The infusion is made by macerating 1 ounce (30 Gm.) of the drug with 1 pint (480 Cc.) of boiling water for 2 hours. The dose of the drug in substance is stated to be from 20 to 30 grains (1.3–2 Gm.); of the infusion, from 1 to 2 ounces (30–60 Cc.); of the fluidextract, from 20 to 30 minims (1.30–2 Cc.).

Other Species.—The genus *Eupatorium*, L., as at present regarded, contains some 400 species, but we believe it should be divided. All but about a dozen are American, and most of them are tropical. In almost every part of America, and in some other countries, one or more species are used domestically as thoroughwort is used here. The use of nearly 50 species has been so recorded, but we can here mention only the most important of them.

The roots of *E. purpureum* L. and *E. maculatum* L., both known as *Purple boneset*, *Joe-pye weed*, *Queen-of-the-meadow*, *Near-weed*, *Skunk-weed*, or *Devil's-root*, both with reddish-purple flowers and whorled leaves, the former very abundant in low lands throughout eastern and central North America, the latter (*Spotted joe-pye weed*, etc.) in the middle-eastern coast region, are used partly for their astringent, partly for their diuretic effects. It yielded to assay 0.07 per cent. of volatile oil, 0.25 per cent. of resin, 0.53 per cent. of fat, 0.29 per cent. of wax, 2.76

per cent. of gum, 2.88 per cent. of dextrin, 2.04 per cent. of saccharose, 2.29 per cent. of glucose, 1.82 per cent. of calcium oxalate, euparin, and 14.9 per cent. of ash. *Euparin* ($C_{12}H_{11}O_3$) is a yellow neutral crystalline principle, soluble in hot alcohol, slightly so in cold alcohol, and insoluble in water. It is distinct from quercitrin or quercetin, which it was formerly thought to be. Its crystals may deposit from the fluid extract.

The following species are rather richer in volatile oil than *E. perfoliatum*, and are used rather for their aromatic and diuretic properties: *E. ageratoides* L. f., the *White* or *Indian sanicle*, *White snake-root*, or *Pool-root*, common, chiefly in rich rocky woodlands of eastern North America, slender, weak, widely branching, nearly or quite smooth, the leaves slenderly petioled, thin, 7 to 15 Cm. (3 to 6 In.) long, broadly ovate, acuminate and acute, sharply and irregularly dentate-serrate, 3-ribbed, the flowers beautiful, snow-white, about 10 to 30 in the head, the involucre narrowly bell-shaped, about 4 Mm. ($\frac{1}{6}$ In.) long; *E. aromaticum* L., the *Small boneset* or *Wild horehound*, chiefly of the Atlantic coast region, is slender, erect, nearly simple, very finely hairy, the leaves 4 to 8 Cm. ($1\frac{1}{2}$ to 3 In.) long, broadly ovate, with mostly cordate base and acute or obtuse summit, thickish, shortly and stoutly petioled, serrate, 3-nerved, the heads crowded, dull-white, scarcely so large as the last, about 10–25-flowered; *E. cœlestinum* L., the *Blue boneset* or *Mist flower*, abundant in damp lands of the southern Atlantic and Gulf States, the flowers like those of *E. ageratoides*, but bright-blue; *E. capillifolium* (Lam.) Small (*Artemisia c.* Lam.; *E. fœniculoides* Walt.; *E. fœniculaceum* Willd.), the *Dog-fennel* or *Hog-weed* of our southern coast region and the West Indies, the heads very small and innumerable, the leaves divided into numerous capillary divisions several inches in length, its volatile oil peppery-biting; *E. cannabinum* L., the *Hemp*, *Water*, or *Dutch agrimony*, *Water* or *Bastard hemp*, *-Wasserdost* or *Wasserhanf*, is a European species similarly used; *E. Aya-Pana* Vent., the *Aya-pana*, *Nya-pana*, *Heilsamer Wasserdost*, of Brazil, is used there almost exactly as thoroughwort is here, its composition being very similar. It is also one of the very numerous plants there credited with alexipharmic properties.

EUPHORBIACEÆ.—The Spurge Family.

Genera more than 200; species more than 3000, representing almost all habits of growth and exhibiting a high degree of adaptability to varying environment. By its combination of botanical characteristics, the family is peculiarly isolated and its position in the system is problematical. Its economic importance depends almost wholly upon the substances extracted and upon the medicinal uses of its members. Edible products, other than starchy roots (see Tapioca, under AMYLUM), are few, and there are few useful woods or fibers, though some of the former enjoy special uses.

A number of dyes have in past times possessed some degree of importance. The valuable rubbers produced by this family are considered under ELASTICA. The medicinal properties depend chiefly upon two classes of constituents: first, fixed oils or the fatty acids freed by their decomposition, for the typical properties of which see OLEUM RICINI and OLEUM TIGLII; second, substances carried in the milk-juices which characterize the entire family. These medicinal constituents are also in great part responsible for the prevailing and severely poisonous properties, external and internal, though the latter are in some cases due to albuminous substances similar to *ricin* (see OLEUM RICINI).

Cascarilla and some others are used as bitter tonics, but the important medicinal properties may be grouped under two heads: counterirritants, and purgatives or laxatives; depending upon which latter are many and important uses as alteratives, well illustrated in STILLINGIA.

FIXED OILS.

Of the numerous fixed oils which have been expressed from the seeds of these plants the following are of importance:

Aleurites, *Candle-berry*, *Kakuin*, *Lambang*, or *Artist's oil*, is a fixed oil expressed from the seeds of *Aleurites Moluccana* (L.) W. (*Jatropha M.* L.; *A. triloba* Forst.; *Juglans Camirum* Lour.). This is a small tree of the East Indies and Pacific islands, bearing a fruit resembling a small orange in appearance and containing 2 large seeds known as *Candle-nuts*, *Indian Belgaum*, *Tahiti*, *Spanish*, or *Country walnuts*, *Lambang nuts*, *Kukuli*, *Firniss*, or *Kerzennuss*. They yield 60 per cent. of the oil, which belongs to the drying class, is of a clear amber-yellow color, free from odor, and of a bland and pleasant taste. Its properties vary greatly with its character. The seeds are frequently eaten for the sake of the oil, and the oil itself, if obtained without artificial heat and fresh, has no medicinal action; but if expressed between hot plates, perhaps because of the freeing of its fat-acid, perhaps because of the removal with it of some resinous matter, it is a mild and useful purgative in doses of from $\frac{1}{2}$ to 2 ounces. A similar oil is obtained from the seeds of *A. laccifera* W., which yields a kind of lac (see LACCA).

Chinese wood oil is a very similar fixed oil expressed from the seeds of *A. cordata* Steud. (*Elæococca c.* A. Juss.; *E. vernicia* A. Juss.; *Dryandra c.* Thunb.; *D. vernicia* Correa), one of the *Tung-trees* of the East Indies. This oil is a very important article of commerce in Eastern countries, almost wholly replacing paint in Central China. It is brownish and of a disagreeable odor, if extracted by the aid of heat; or nearly odorless and colorless, if cold-drawn. It is somewhat more fluid than castor oil. It has a specific gravity of 0.94 at 15.55° C. (60° F.), remains liquid at —13.3° C. (8° F.). 100 Gm. of the oil require 0.39 Gm. of caustic potash for neutralization and 21.1 Gm. for complete saponification (Davies). Wood oil is said to be the most perfectly drying oil known.

Chinese Tallow.—This is a fat which comprises almost the whole of the pulp of the fruit of *Sapium sebiferum* (L.) Roxb. (*Croton s.* L.; *Excœcaria s.* Muell. Arg.; *Stillingia s.* Mx.), of China and the East Indies. It is white, consists chiefly of palmitin, with a little stearin, and melts at 44.5° C. (112° F.). The seeds contain a drying oil very similar to that of *Aleurites*.

Other fixed oils more or less resembling those of croton and castor are chiefly or wholly responsible for the activity of certain seeds considered under those two titles.

CATHARTIC DRUGS.

Besides the cathartic properties resident in the fixed oils of the seeds already considered, somewhat similar properties, almost always accompanied by more or less emesis, exist in the plant-parts generally, the active constituents being usually carried in the milk-juices, so that the family has yielded a large number of drugs used somewhat like ipecac. Although these uses are at present chiefly by the laity, some of the drugs have occupied a prominent place in professional medicine.

Euphorbia, L.—This genus, which will at length probably be found to comprise nearly a thousand species, has yielded the principal drugs of the group under consideration. The following are the most important of them, the two first described having been long official in the U. S. P.:

E. corollata L. is the *Large-flowering*, *Blooming*, or *Purslane spurge*, or *White purslane* or *Parsley*, *Purging-* or *Emetic-root*, *Apple-root*, or *Wild hippo*, of eastern and central North America. Although all parts of the plant are active, the root has been chiefly employed. The plant is a smooth perennial, growing in sandy and mostly in low situations, with a slender, more or less branched stem, nearly a yard high, bearing alternate, linear-oblong, obtuse leaves, and umbellate-cymose flowers, their involucres white, showy and petal-like, a greenish gland at the base of each bract. The root should be collected in autumn. It is vertical and mostly simple, reaches as much as 2 feet in length and about an inch in thickness, is cylindrical, dark-brown or even blackish, and wrinkled externally. The fracture is nearly smooth and exhibits a thickish white bark underneath the cork, enclosing a whitish, spongy, porous, many-radiate wood. It is almost odorless, sweetish, and afterward warming to the mouth. The root abounds in laticiferous ducts, the latter containing, as usual in the family, resin and gum. There is also considerable starch. The resin is, or carries, the active principle. The presence of a glucoside is conjectural. *Euphorbon* (see *Euphorbium*, below) is present in this and the related drugs. *Euphorbia corollata* is rarely employed in medicine at the present time. Formerly it was occasionally used as an emetic in doses of 20 grains (1.30 Gm.), but because of its irritant and uncertain properties its use has practically been abandoned.

E. Ipecacuanha L., the *North American*, *Carolina*, *Milk*, *Spurge*, *White* or *Wild ipecac*, *Black* or *Ipecac spurge*, occurs abundantly in pure sand along the Atlantic coast. It is quite smooth, the peculiar, slender, cymosely branching, at length diffusely prostrate stems bearing extremely variable leaves, ranging from narrowly linear to broadly oval or obovate. The inflorescence is greenish or more or less purplish, small and inconspicuous. The root is much like the last, but becomes two or three times as long, and is usually not so thick, the outer surface grayish-yellow or brown, the wood yellowish. Its constituents are practically the same as those of the last.

E. Cyparisias L., the *Cypress*, *Balsam*, or *Quacksalver's spurge*, *Graveyard weed*, *Bonaparte's crown*, or *Tree moss*, is a well-known European species of cultivation, frequently seen in cemeteries, its densely tufted slender stems occasionally reaching a foot in height, and densely leafy, the leaves linear, an inch or two in length and bluish-green, the terminal umbellate inflorescence bright-yellow. Its root is light-colored, slender, and somewhat crooked.

E. Lathyrus L. (see also under Oleum Tiglii) is purgative in all its parts, and both the roots and herbage have long been used in Europe.

E. maculata L., the *Spotted spurge*, an exceedingly common annual prostrate weed, found in nearly all cultivated grounds throughout America, represents a group used by eclectics and homœopaths, with claims for properties more or less special, but all probably closely similar as to both constituents and properties. It has been found to contain caout-

chouc, resin, tannin, and apparently euphorbon. To this medicinal group belong the following: *E. Esculа* L., the *Leafy spurge* of Europe; *E. Helioscopia* L., the *Sun* or *Wart spurge, Wart weed, Churn staff, Seven sisters*, etc., of Europe; *E. humistrata* Engl., of central North America; *E. hypericifolia* L., commonly growing with *E. maculata* and very abundant; *E. portulacoides* Gay, of Chile; *E. lata* Engelm, of the United States; *E. marginata* Pursh, the *White-margined spurge* or *Mountain snow*, a plant of striking appearance, growing throughout the western United States; *E. Peplus* L., native of Europe and almost invariably naturalized. *Euphorbia maculata* is said to be a valuable astringent in the treatment of chronic diarrhœa, and an infusion of it may be employed as an injection in the treatment of leucorrhœa.

Jatropha, L.—The seeds of several species of this genus are considered in connection with Oleum Tiglii. The roots, and in some cases the herbage, of several species are also employed. In Honduras, the large cylindrical root of one is called *Ruibarbo* (rhubarb), and is there generally employed as a substitute for that drug, which it closely resembles in the fresh state. *J. macrorhiza* Benth., of the southwestern United States and Mexico, is similarly employed, and has been introduced to the American profession. The root is described as tuberous, short, and very thick. Its fluid extract is said to be a laxative-cholagogue in doses of ½ to 2 fluidrachms. The seeds and their oil are also employed, the action of the latter being apparently similar to that of croton oil.

Croton dioicum Cav.—The roots and seeds of this Mexican plant, *Yerba del Zorillo*, are there employed as a purgative and alterative. The dose of the powdered dried root is ½ to 1½ Gm.

Phyllanthus Niruri L., the *Bhuimy-amali, Daou Marasin*, or *Pombinha*, of various tropical countries, is a much used laxative-alterative, especially against jaundice. Many species of *Phyllanthus* are employed as diuretics.

Acalypha Indica L., the *Kuppi, Dadaro, Chalmari*, or *Brennkraut*, is very largely employed in the East Indies as a purgative and anthelmintic, as are several species of *Tragia*, of both the Old and New World tropics.

ALTERATIVE DRUGS.

Under this term, a large number of species of *Euphorbia* and related genera have been employed in syphilis and related diseases, and are still so used by many physicians. The alterative effects, which are undoubtedly produced, appear to result from the depurative action dependent upon laxation or mild catharsis.

Mercurialis annua L., the *Mercury herb* or *French mercury*, and *M. perennis* L., the *Dog's mercury, Kentish balsam, Bristol weed*, or *Cheadle*, both of Europe, are thus employed. They have been found to contain the volatile alkaloid *monomethylamine*, with a little *trimethylamine*, to which are doubtless due the acrid properties, which are destroyed by boiling.

Euphorbia pilulifera L. is commonly known as the *Pill-bearing spurge*, in allusion to its small globular axillary inflorescences. It is called *Queensland asthma weed, Cat's hair*, etc. It is an exceedingly common little hairy weed, in all tropical countries, the stems about a foot long and covered with long, rather coarse yellowish hairs, the entire plant, including the root, otherwise of a red or reddish-green color. Its principal constituents are resins, which are indefinitely described as "glucosidal." It is distinguished by its transversely wrinkled seeds from the closely similar *E. parviflora*, which have been falsely substituted, the seeds of which are merely granular or slightly papillose. *Euphorbia pilulifera* has been employed by some practitioners with asserted success in the treatment of subacute and chronic inflammation of the respiratory tract. It may be given in doses of from ½ to 1 drachm (2–4 Cc.) of a fluidextract, 3 times daily; but because of its acrid properties this amount may occasion gastric pain and nausea. Because of the fact that it stimulates the circulation and respiration it has also been given with good results in the treatment of asthma.

The bark of *Croton erythæma* Mart. is used in Brazil as an astringent in intestinal and genito-urinary diseases, under the name *Casca de sangre de Drago*, in the form of a syrupy extract.

COUNTERIRRITANTS.

The milk-juices of many of the *Euphorbiaceæ* are more or less irritant to the skin, some of them so intensely as to be dangerous cutaneous poisons. The name *Blinding-tree* has been applied to the *Excœcaria Agallocha* L., of the East Indian tidal forests, because of the destruction of eyesight sometimes caused by the accidental contact of its milky juice. An examination of this latex has failed to reveal anything of importance, with the exception of 25 to 30 per cent. of the resin *fluavil*, and nothing to account for its irritant action.

Hura.—Precisely similar to the blinding-tree, as to accidents to sight, is *Hura crepitans* L. (*H. Brasiliensis* W.), the *Sandbox-tree, Monkey's dinner-bell, Ajuapar, Assacu, Javilla, Solimán, Habilla de San Ignacio*. This is a good-sized forest-tree, very common and abundant throughout tropical America. Its trunk is beset with short, stout, pyramidal spines, and the

caustic milky juice of the bark appears to be retained under pressure, since it spatters out with some slight violence. Since the wood is very quickly destroyed by borers and decays when the continuity of the bark is destroyed, the juice and the spines together apparently constitute a needed defensive provision. The apple-shaped fruit is peculiar for its habit of bursting, when dry, with a loud report. The juice, and hence the bark, contain two acrid principles, one oily and volatile, and the other (*hurin*) crystallizable. Both bark and leaves are used externally as counterirritants and for their anthelmintic properties. For internal use, ½ ounce of the bark is boiled in 1 pint of water down to ½ pint; while for external use, as an antirheumatic lotion, a saturated aqueous infusion is employed. Overdoses are dangerously emetico-cathartic. The fixed oil of the seeds is occasionally used as a drastic.

Alvelos, or *Alveloz*, is the very similar juice, used fresh or preserved by the aid of salicylic acid, of *Euphorbia heterodoxa* Muell. Arg., of Brazil. It has been largely employed by resident physicians as an escharotic application to morbid growths, especially those of a malignant nature. It is applied either pure or in the form of the resinous precipitate. For a mild action, a 3 per cent. ointment of the resin is commonly employed. That absorption can occur is evident from an irritant and peculiarly odorous renal excretion which often appears after continued application.

Euphorbium, P. G. (*Euphorbe, Gomme-résine d'euphorbe*, Fr.; *Euforbio*, Sp.), is a gum-resin obtained from *Euphorbia resinifera* Berg., a peculiar, cactus-like plant of Morocco, with quadrangular stems, and very spiny from its modified stipules, otherwise leafless. The milk-juice exudes and coagulates upon the spines, and is collected as *Euphorbium*. So intensely irritating is the dust that the mouth and nose of the collector require careful protection. It occurs in conical or triangular-conical pieces, often containing a perforation where it was removed from the spine, or in irregular fragments of such forms. The spines themselves are often imbedded in the fragments. It is of a light brownish-yellow, somewhat waxy and translucent, brittle, almost odorless, but violently sternutatory, and leaving an acrid and burning after-taste. When heated, it emits a slightly benzoin-like odor, and it is fusible and combustible like other resins. It yields a turbid mixture, but not an emulsion, with water, and is not perfectly soluble in any of the ordinary solvents. Euphorbium consists principally of two resins: one (about 40 per cent.) amorphous, bitter and acrid, apparently of the formula $C_{10}H_{16}O_2$; the other (about 22 per cent.), *euphorbon* ($C_{13}H_{22}O$), crystalline and soluble in ether, benzene, benzin, amyl alcohol, chloroform, and hot alcohol, but requiring 60 parts of alcohol at the ordinary temperature. The acridity of the first-mentioned resin is destroyed by boiling in a weak solution of potassium permanganate. There are also 18 per cent. of gum, 12 per cent. of malates, chiefly of calcium and sodium, and 10 per cent. of mineral matter.

The euphorbium district, upon the lower slopes of the Atlas Mountains, appears capable of supplying any reasonable demand, but for various reasons commercial supplies have been very irregular, and a number of other products, very similar and all apparently from related species of *Euphorbia*, have appeared. It is highly probable that many species of the genus are capable of yielding substances practically identical with euphorbium. The fresh juice and the powdered dry plant are powerful stimulants and irritant cathartics and emetics. When locally applied to the skin they produce vesication, and ointments and plasters containing this drug may be used as counterirritants in the treatment of sciatica and similar conditions. Because of its irritant properties it is no longer employed in internal medicine. This drug is of considerable commercial value, as it is used in coating the bottom of vessels and other objects liable to the destructive attacks of marine worms.

Manchineel, or *Manzanillo*, is the resinous exudation, also the fruit, of *Hippomane Mancinella* L., a large West Indian tree. Marvellous stories are told of the intensity of its poisonous properties. The fruit poisons the fish of the waters into which it falls. An arrow poison is said to be made from the milky juice, which is externally caustic and internally an emetico-cathartic poison. The principal poisonous constituent is claimed to be volatile, but the correctness of the statement is very doubtful.

The milky juice of *Euphorbia Drummondii* Boisa, of Australia, is externally irritant and is a destructive cattle poison, locally known as *Caustic creeper*. A peculiar symptom of poisoning by it is said to be the enormous swelling of the head, followed by suppuration. A claim has been made that it contains a crystalline alkaloid. According to Maiden, E. *alsiniflora* Baill. acts similarly.

MISCELLANEOUS SUBSTANCES.

Jatropha urens L. (*Cnidoscolus neglectus* Pohl.), the *Fructo de Arradiabo* of tropical America, has its leaves and fruit beset with peculiar glandular hairs, which sting violently, blister, and, due partly to the irritation and partly apparently to absorption, cause severe fever. The fresh leaves, thoroughly macerated, are applied as a rubefacient or stimulating poultice. The

seeds, as in so many other species, contain a purgative fixed oil to the extent of about 31 per cent.

Crozophora tinctoria A. Juss. yields an indigo, and is a fatal poison, the symptoms being great abdominal pain, constipation, jaundice, and bilious vomiting, bloody and bilious urine, bleeding at the nose, dilated pupil, and stupor.

Cleistanthus collinus Benth. (*Lebedieropsis orbicularis* Muell. Arg.), the *Kodarsi*, *Telugu*, or *Oduvan*, is an excellent timber-tree of India, all parts of which are poisonous, the pericarp especially so, and used for criminal purposes. An infusion, or powder, of the bark, is promptly fatal to insect parasites on animals. This bark is dark-brown externally, otherwise reddish-brown, its powder light-red, without special odor, the taste merely astringent. It yields one-third of its weight of an excellent tannin. It has been claimed that this tannin is the poisonous constituent, but the statement is open to doubt, there being probably some poisonous constituent associated with it.

Toxicodendron Capense Thunb. (*Hyænanche globosa* Lamb.), of South Africa, is highly poisonous. Its active principle is the amaroid *hyænanchin*, which acts like strychnine, though affecting the cerebrum more than that substance.

The bark of *Flueggia leucopirus* W., of the East Indies, is a fish poison, and many species of the genus *Phyllanthus* are also so used. *Phyllanthus Urinaria* L., the *Jaramla* or *Tamravalli* of the East Indies, is used as a powerful diuretic, carminative, and antispasmodic, and is abortifacient.

Not less than 300 other species of this remarkable family are recorded in literature as having more or less important aboriginal or domestic uses as fish poisons, or as being otherwise poisonous, as purgatives, diuretics, anthelmintics, carminatives, antispasmodics, counter-irritants, vulneraries, insecticides, etc.

Buxaceæ.—This is a very small family of only 6 genera and about 30 species, and is closely related to the *Euphorbiaceæ*. A single species, *Buxus sempervirens* L., has been utilized in medicine. This is the well-known evergreen shrub cultivated under the name of *Box*. Its twigs are very densely leafy, and the leaves, the part used, are about half an inch in length, ovate, entire, smooth, thick and coriaceous, and dark-green. They have a peculiar, rather disagreeable odor, and a bitter and somewhat astringent taste. They have been found to contain, besides a small amount of tannin and unimportant constituents, a butyraceous volatile oil, and two alkaloids, *buxine* and *parabuxine*, the former being the important constituent and chiefly responsible for the bitter taste. Buxine is now regarded as identical with beberine, an account of which is given in connection with Nectandra Bark. Box has been found narcotic and sedative in full doses, emetico-cathartic and convulsant in overdose. It has been used as a bitter tonic and antiperiodic, and also as an alterative in rheumatism, syphilis, etc. Given in decoction, it exerts a diaphoretic action.

EXTRACTA.—Extracts.

Extraits, Fr.; *Extrakte*, G.; *Estratto*, It.; *Extractos*, Sp.

Extracts are permanent, soft, solid, or dry preparations obtained by evaporation of a solution of the medicinal principles of drugs. These solutions are prepared, as a rule, from the powdered dry drugs by exhausting them with appropriate solvents, preferably by percolation, the solvents or menstrua employed being either water, water and alcohol, alcohol, or ether. According to the different menstrua used in the manufacture, extracts are designated as aqueous, hydro-alcoholic, alcoholic, and ethereal extracts, the last-named class being recognized more particularly under the name of oleoresins. In fresh plants the solution of the medicinal principle is represented by the juice, and may be obtained by expression; extracts prepared by simple evaporation of the fresh juice of a plant are known as inspissated juices.

The U. S. Pharmacopœia does not recognize inspissated juices, since the narcotic herbs which are extensively used in Europe for this purpose are not indigenous in the United States. The juice is obtained from the fresh plant, after removal of extraneous matter, by bruising in a stone mortar with the aid of a hard-wood pestle until reduced to a smooth pulpy mass, which is then strongly expressed in canvas bags; in order to recover all the juice, the residue is often mixed with water and again expressed. When the plant is not sufficiently moist to enable the formation of a soft pulp, water is sprinkled over it from time to time.

Besides the medicinal principles, the expressed juices of fresh herbs contain also mucilaginous and albuminous matter in solution and variable quantities of chlorophyl or green coloring-matter in suspension; of these, the albuminous principles are most objectionable, as upon concentration of the juice they undergo change and are likely to render the finished extract tough and insoluble. When roots are expressed, as in the case of the corm of colchicum, starch, which is present in the juice in place of chlorophyl, passes

through the press-cloth, and must be removed by subsidence and decantation. The British, German, and French pharmacopœias direct the removal of albuminous matter by heating the juice to from 80° to 90° C. (176° to 194° F.) and filtering. The coagulated albumin envelops the green coloring-matter and removes it also, which fact is disregarded in Germany and France, and accounts for the brown color of the extracts made from fresh herbs in those countries. In Great Britain the chlorophyl is carefully separated by heating the fresh juice to 55° C. (131° F.) and straining through calico; the liquid is then heated to 94° C. (201.2° F.), and, after filtering out the coagulated albumin, evaporated to a thin syrup, the chlorophyl is reincorporated, and evaporation continued, with constant stirring, at a temperature not exceeding 60° C. (140° F.), to the proper consistence. This explains the firm condition and fine green color of some of the British narcotic extracts. The German Pharmacopœia alone provides for the removal of the gummy matter, and hence its narcotic extracts are relatively much stronger than those of the British and French pharmacopœias. The solubility of gummy matter is not in any way affected by heating, and therefore the filtered liquid, after removal of the coagulated albumin and chlorophyl, is evaporated to 10 per cent. of the original weight of the fresh herb used, mixed with an equal volume of alcohol, and set aside for 24 hours to allow the precipitated gum to subside. After decantation the precipitate is washed with diluted alcohol, which is added to the other clear liquid, and the whole evaporated to the condition of a soft solid.

Consistence of Extracts.—The U. S. Pharmacopœia recognizes two kinds of solid extracts, those of pilular consistence and those evaporated to complete dryness. A pilular consistence is such a condition as will allow the extract to be rolled into masses of pilular form without adhering to the fingers or subsequently losing shape; this is rarely met with in the market, except in the case of British narcotic extracts, which derive their firmness chiefly from the chlorophyl and gummy matter present. Pilular consistence for the extracts made in this country, by the official formulas, is practically unattainable at all seasons, for extracts made in summer are likely to become too hard in winter, while those evaporated to the proper consistence in winter are prone to soften in summer. Some extracts become tough and hard in the course of time, but may be retained in proper condition by incorporating with them, while still warm, 10 per cent. of their weight of glycerin. The condition of complete dryness is not applicable to all extracts, but can be readily maintained for all those so directed by the Pharmacopœia, provided heat and moisture be excluded.

Of late years, powdered extracts have come extensively into demand, and their convenience in dispensing pharmacy cannot be denied. Sugar of milk is to be preferred, wherever possible, as a diluent on account of its perfect solubility, but in some cases finely powdered licorice root has been found much better for maintaining the pulverulent condition of the extract, especially during damp or warm weather. The respective finely powdered drugs have also been used with success as diluents. Large manufacturers, as a rule, now prepare powdered extracts by evaporating the percolate to dryness in vacuum stills, where concentration and desiccation can be effected at a low temperature without possible injury to the constituents in solution; the dry extract is subsequently reduced to fine powder in pebble-mills, whereby heat is avoided. Powdered extracts may readily be prepared of definite strength, especially those which owe their medicinal value to alkaloidal or resinous constituents; and in the absence of specific constituents to be used as a basis for standardization, the Pharmacopœia has directed that they shall bear a definite relation to the crude drugs from which they have been respectively made. Such relation represents in some cases 4 times and in others 10 times the weight of crude drug. In Germany, powdered narcotic extracts are prepared of one-half the original strength of the extract, by addition of finely powdered licorice root.

The Abstracts of the U. S. Pharmacopœia for 1880 were closely allied to the present powdered extracts. They were much weaker preparations, being made to represent twice their weight of crude drug. The general plan for preparing abstracts was to make a fluidextract of the drug with strong alcohol, mix this with some sugar of milk, dry by spontaneous evaporation in a warm place, then add sufficient sugar of milk to bring the product up to one-half the weight of the powdered drug used, and finally reduce to a fine powder.

To avoid the tendency of powdered extracts to cake, caused by their hygroscopic nature, A. B. Lyons, in 1899, introduced a line of extracts in the form of scales, for

which it is claimed that they are in many respects superior to powdered extracts. These scale extracts are obtained, according to the statement of Lyons, by first preparing a highly concentrated liquid extract of the respective drugs by the use of menstrua which leave behind as much inert constituents as possible. Having ascertained by experiment how much dry residue is obtainable from these liquid extracts, sufficient acacia is added to insure a definite standard of strength, which has previously been fixed upon, in the finished product. The solution is then spread on plates of glass and dried in a current of warm air. The particular menstrua used for the different drugs have thus far not been made known. Scale extracts somewhat resemble the iron scale salts in appearance, and with warm water readily form more or less turbid solutions. As in the case of powdered extracts, those owing their value to alkaloids are brought to a definite standard of alkaloidal percentage; but in the case of other scale extracts a uniform strength has been adopted corresponding to 4 times the weight of the drug represented.

Changes by Evaporation.—All plants contain one or more principles, which, though originally colorless, are very easily altered under the influence of air and heat, acquiring a yellow or brown color. It is not known whether the so-called *colorless extractive* is alike in all plants, neither is its composition or the nature of the changes produced under the conditions mentioned known, except that the heat of boiling water and the prolonged action of oxygen will convert it ultimately into a blackish insoluble substance, to which the name *apotheme* has been given, and which appears to be allied to *humin*. Extractive is almost insoluble in absolute alcohol and ether, but dissolves freely in weaker alcohol and water, and is removed from its solution by animal charcoal and aluminum hydroxide, the more readily after it has become colored by oxidation. It is with difficulty freed from admixtures, and the terms sweet, bitter, acrid, etc., as applied to extractives, refer to the same body in a more or less altered condition, combined or intimately mixed with other principles to which the peculiar taste is due. The injurious influence of air and heat upon the vegetable juices is mainly confined to the alterations of this extractive, and extends, in a limited degree only, to the majority of the well-defined principles. Its effects have been much overrated, except as regards the appearance of the extracts. The color of the different extracts varies with the nature of the drug from which they have been made, but should never be black. The characteristic taste, and to some extent also the odor of the drug, should be perceived in its extract, and it should yield a nearly clear or moderately turbid solution with the menstruum used in its preparation.

Aqueous Extracts.—While decoction in some cases increases the yield of extract, by bringing into solution starch and other inert matter, it more frequently injures the quality of the product by inducing changes in certain principles which do not occur by infusion at lower temperatures. There is but one instance, that of extract of logwood, in which the Pharmacopœia directs extraction by boiling, and this is on account of the difficulty of exhausting the tough wood. In Europe, digestion is still preferred for a few aqueous extracts, but, as a rule, maceration and percolation with cold water have been found to yield superior extracts. For the better extraction of the active virtues of the drug, an addition of acid or alkali is sometimes made, as in the case of the official extract of colchicum root and pure extract of glycyrrhiza. In the preparation of aqueous extracts the solution is freed from objectionable matter, whenever necessary, by heating to the boiling-point and straining before final evaporation.

In 1889, the plan of concentrating large volumes of aqueous solutions of extracts by means of cold was formulated by M. Adrian, a French pharmacist, and put into practice on a large scale. Following the suggestions of Herrera (1877), M. Adrian subjects the filtered aqueous solutions to a temperature of —20° C. (—4° F.), in an ammonia ice-apparatus, and thus obtains large blocks of ice in which the extractive solution is enveloped, the pure water alone freezing; these blocks of ice are rapidly converted into snow by means of large shaving machines. Another French pharmacist, M. Vee, prefers to convert the aqueous solution into a crystalline magma instead of solid blocks of ice, and accomplishes this by keeping the liquid in constant agitation during the freezing process. The snow-like mass is placed in centrifugal extractors, where about 75 per cent. of water is removed. The remaining solution is again subjected to cold (even a lower temperature than at first), when a syrupy liquid is obtained, which can readily be evaporated to a solid extract, in a vacuum apparatus, at a temperature not exceeding 30° C. (86° F.). Extracts thus prepared are lighter in color than those obtained by ordinary vacuum or

open-air evaporation, form almost clear solutions with water, and possess the odor and taste of the drug in a marked degree. It has been found that all vegetable matter in solution is retained in its original condition, even the albumin, water alone being removed.

Alcoholic and Hydro-alcoholic Extracts.—For these two classes of extracts percolation is decidedly the best method of extracting the medicinal principles of the drugs, the operation being continued to complete exhaustion. If percolation be conducted at the rate of 5 drops per minute, from 3 to 4 Cc. of percolate should suffice for each Gm. of drug. In many cases, particularly those of the mydriatic drugs, active principles of which are easily split up by prolonged application of heat, it is very desirable to set aside the first third of the percolate as reserve, to be incorporated with the remainder when this has been reduced to the condition of a syrupy fluid. The recovery of the alcohol is effected, as in the case of fluidextracts, by distillation in a suitable still, the final evaporation being conducted in porcelain dishes, with constant stirring, so as to insure a homogeneous mass and prevent the separation of resinous and other matter. As the concentration of the solution approaches the condition of a thick syrup, continuous stirring is also necessary, to prevent the formation of a film, which, becoming gradually thicker, retards evaporation of moisture, and consequently causes an accumulation of heat within the mass, to the possible injury of some of the constituents. In large manufacturing establishments mechanical stirrers are conveniently operated by steam, electric, or water motors. Metallic stirrers should never be employed, only those of porcelain, glass, or wood being permissible. To guard against the separation of coloring-matter or changes in other constituents of the solution, concentration should always be effected on a water-bath, at a temperature not exceeding 55° C. (131° F.).

EXTRACTUM ALOES, *U. S., P. G.*—Extract of Aloes.

Extractum aloes barbadensis, Br.; *Extrait d'aloès*, Fr.; *Aloeextrakt*, G.; *Estratto di aloe acquosa*, It.

Preparation.—Aloes, 100 Gm.; boiling distilled water, 1000 Cc. Mix the aloes with the water in a suitable vessel, stirring constantly, until the particles of aloes are thoroughly disintegrated, and let the mixture stand for 12 hours; then pour off the clear liquor, strain the residue, mix the liquids, and evaporate to dryness by means of a water- or steam-bath.—U. S.

The Br. P. process is almost identical with the foregoing, except that the mixture is set aside for 24 hours and the decanted and strained liquid is directed to be evaporated at a temperature not exceeding 60° C. (140° F.). The P. G. directs that the aloes be dissolved in 5 parts of boiling water, the solution then mixed with 5 parts of cold water and set aside for 2 days, after which it is decanted and evaporated to dryness. German extract of aloes is made from Cape aloes, since that variety only is officially recognized.

The object of using so large a proportion of water is to avoid the admixture of resin, for a concentrated aqueous solution of aloes retains in solution the resin present, whereas a dilute solution again deposits it on cooling. Complete separation of resinous matter is impossible, and hence the extract does not yield a perfectly clear solution with water.

The yield of dry extract varies from 20 to 50 per cent. according to the variety of aloes and care used in manufacture. When powdered, the extract is of a yellowish-brown color.

Action and Uses.—See ALOES. Dose, from 1 to 2 grains (0.06–0.12 Gm.).

EXTRACTUM ANTHEMIDIS, *Br.*—Extract of Chamomile.

Extractum chamomillæ Romanæ.—Extrait de camomille romaine, Fr.; *Römisch-Kamillenextrakt*, G.

Preparation.—Take of chamomile flowers, 1 pound; oil of chamomile, 15 minims; distilled water, 1 gallon. Boil the chamomile flowers with the water until the volume is reduced to one-half, then strain, press, and filter. Evaporate the filtrate to the consistence of a soft extract, adding the oil of chamomile toward the end of the process.—Br.

It is a dark-brown extract having the odor and bitter taste of chamomile. It would seem not to be very difficult to work out a better process, in which the protracted boiling should be avoided.

Action and Uses.—See ANTHEMIS. Dose, from 2 to 10 grains (0.12–0.60 Gm.).

EXTRACTUM BELLADONNÆ FOLIORUM, *U. S.*—Extract of Belladonna Leaves.

Extractum belladonnæ foliorum alcoholicum, U. S., 1890.—*Extrait de belladone alcoolique*, Fr.; *Spirituöses Tollkirschenextrakt*, G.; *Estratto di belladonna*, It.

Preparation.—Belladonna leaves, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity. Mix 2000 Cc. of alcohol with 1000 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until 3000 Cc. of tincture are obtained or the belladonna leaves are exhausted. Reserve the first 900 Cc. of the percolate, evaporate the remainder to 100 Cc. at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence.

When assayed by the process which follows, extract of belladonna leaves should be found to contain not less than 1.4 per cent. of total alkaloids. Should it be found by assay to contain more than this percentage, sufficient sugar of milk should be added to reduce it to the standard of 1.4 per cent.

Assay of Extract of Belladonna Leaves.—Extract of belladonna leaves, 5 Gm.; alcohol, ammonia water, distilled water, chloroform, normal sulphuric acid, one-tenth normal sulphuric acid, one-fiftieth normal potassium hydroxide solution, hæmatoxylin or iodeosin test-solution, of each a sufficient quantity. Weigh into a small dish 5 Gm. of extract of belladonna leaves and dissolve it in a mixture of alcohol 5 Cc., distilled water 10 Cc., ammonia water 2 Cc., and chloroform 20 Cc. When dissolved, transfer it to a separator, rinsing the dish with a little alcohol. Cork the separator and shake for several minutes. Draw off the chloroformic layer into a second separator, and add to the contents of the first separator 10 Cc. more of chloroform. Shake for several minutes, allow to separate, and again draw off the chloroformic layer into the second separator. Repeat this with 10 Cc. more of chloroform. To the united chloroformic solutions in the second separator add 10 Cc. of normal sulphuric acid and 10 Cc. of distilled water, and shake for several minutes. Draw off the chloroformic layer, after the liquids have separated, into a clean separator, and the aqueous fluid into a beaker, and repeat the process by adding to the chloroformic fluid 10 Cc. of distilled water and 1 Cc. of normal sulphuric acid. Draw off the chloroformic layer, rejecting the same, and then draw the acid fluid into the beaker. Filter the combined acid aqueous solutions in the beaker through a pledget of cotton into a clean separator, washing the last separator, beaker, and funnel with about 10 Cc. of distilled water. To the acid fluid in the separator add 10 Cc. of chloroform and sufficient ammonia water to produce a distinctly alkaline reaction. Shake for several minutes, and when the liquids have separated, draw off the chloroformic layer into a beaker. Repeat this process with 2 portions of 10 Cc. of each of chloroform, and evaporate the combined chloroformic liquids in the beaker to dryness on a water-bath containing warm water; dissolve the residue in 3 Cc. of ether, and allow the latter to evaporate completely. To the alkaloidal residue add 5 Cc. of tenth-normal sulphuric acid and 5 drops of hematoxylin test-solution, then titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.0287, and this product by 20, to obtain the percentage of mydriatic alkaloids contained in the extract of belladonna leaves. The figure 0.0287 represents the weight in grammes of mydriatic alkaloids (mainly atropine) required to neutralize 1 Cc. of tenth-normal sulphuric acid.—U. S.

25 avoirdupois ounces of the powdered leaves should be moistened with about 10 fluidounces of the menstruum, composed of alcohol 2 volumes and water 1 volume, and the first 22 fluidounces of the percolate set aside as a reserve; the remainder of the percolate is to be evaporated to $2\frac{1}{2}$ fluidounces before it is incorporated with the reserve portion for final evaporation to a pilular consistence.

Extract of belladonna, made by the above formula, has a brown-green color and the characteristic odor and bitter taste of belladonna leaves. It is admirably adapted for use in the form of solutions, pill-masses, ointments, and suppositories, and for administration in powders may be rubbed down with sugar of milk.

The quantity of extract (5 Gm.) directed for the assay by the U. S. P. is too large, as the liquid will be too deeply colored to note the separation of the chloroformic solu-

tion. 2 Gm. will be quite sufficient, in which case the final weight of alkaloids must be multiplied by 50 instead of 20.

Extractum Belladonnæ Alcoholicum of the Br. P. is made by carefully evaporating standardized liquid extract of belladonna root to a thin syrup, adding to it the required quantity of sugar of milk (as previously determined from the data obtained in a separate experiment), and continuing the evaporation until the extract weighs 15 ounces for every 20 fluidounces of the liquid extract used. This alcoholic extract of belladonna contains 1 per cent. of the alkaloids of the root, and is of about one-third the strength of the same preparation of the Br. P. of 1885.

Extractum Belladonnæ Viride of the Br. P. is an inspissated juice of fresh belladonna herb, prepared in accordance with the method given on page 590 It has a brownish-green color, and is used in the same dose as the alcoholic extract, although no definite alkaloidal content is officially required.

Extractum Belladonnæ of the P. G. is an alcoholic extract obtained by treating the juice of fresh belladonna herb, after concentration by heating to 80° C. (176° F.), with an equal weight of alcohol for 24 hours, then straining and treating the residue with diluted alcohol and decanting. The mixed clear liquids are evaporated to a pilular extract, which is required to contain about 1.5 per cent. of alkaloids. The extract has a dark-brown color and yields an almost clear solution with water.

Action and Uses.—See BELLADONNA. Dose, from $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.).

EXTRACTUM CANNABIS INDICÆ, *U. S.*, *Br.*—Extract of Indian Cannabis.

Extract of Indian hemp, E.; *Extrait de chanvre indien*, Fr.; *Indisch-Hanfextrakt*, G.

Preparation.—Indian cannabis, in No. 20 powder, 1000 Gm.; alcohol, a sufficient quantity. Moisten the powder with 300 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the cannabis is exhausted. By means of a water-bath distil off the alcohol from the tincture, and, having placed the residue in a porcelain capsule, evaporate it on a water-bath to a pilular consistence.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of alcohol.

The process of the Br. P. is practically identical with the foregoing. The yield is from 12 to 14 per cent. The extract is of a blackish-green color, and has a slight but heavy narcotic odor and a bitter taste. It should be completely insoluble in water, and dissolve in alcohol, ether, chloroform, and oil of turpentine; its alcoholic solution should be precipitated by aqueous solution of potassium or sodium hydroxide, the resin being insoluble in alkalies. Nitric acid converts the extract into an orange-red resin, which after washing with water has the color of gamboge (Procter, 1864).

It is well known that liquid preparations of Indian cannabis deteriorate during evaporation, especially if the latter be conducted at ordinary atmospheric pressure. The active constituents of the drug undergo oxidation, and hence the resulting extract is often met with of indifferent quality. Concentration of the percolate at a low temperature, and preferably in a vacuum apparatus, will yield the best preparation, provided the drug has not deteriorated from age.

While chiefly exhibited in pill-form, extract of Indian cannabis is sometimes prescribed in mixtures, and can then be best kept in suspension by dissolving it in a small quantity of oil of sweet almond and emulsifying the solution.

Action and Uses.—See CANNABIS INDICA. Beginning dose, from $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.), which may be increased as needed.

EXTRACTUM CARNIS.—Extract of Beef.

Extract of beef, E.; *Extrait de viande, Extrait de bœuf*, Fr.; *Fleischextrakt*, G.

Extract of meat is said to have been brought into notice and described by Proust in 1801. Since then various suggestions have been offered as improvements in manufacture, and about 1855 Liebig published a process for making extract of meat on a large com-

mercial scale, which is probably still followed, with slight modifications, by the leading manufacturers, notably those of South America—the Liebig Company at Fray-Bentos, in Uraguay, and the Kemmerich Company in Argentina. Since 1870 considerable quantities of extract of meat have been manufactured by the large packing firms of the western United States, which closely resemble the South American preparations and are largely used. In Australia mutton has been used for many years in place of beef for making extract of meat. In addition to the solid beef-extracts, several fluid preparations have been marketed and found considerable favor among physicians, as Valentine's Meat Juice, Cibil's Fluid Beef, Johnston's Fluid Beef, Wyeth's Beef Juice, etc.

Preparation.—Solid extracts of meat, of the type of the Liebig extract, are usually made as follows: Fresh lean beef, freed from sinews, is thoroughly chopped or minced in suitable apparatus and extracted with 10 times its weight of water heated by steam. The mixture is strained and the liquid set aside for a few hours to become cold, when fat and gelatin separate and are removed. Finally the liquid is evaporated in a vacuum apparatus to the consistence of a soft extract. In some establishments the original mixture of meat and water, or the subsequent strained liquid, is boiled for some time to get rid of the coagulable albumin.

The yield of extract, which, when obtained by the above process, consists wholly of the water-soluble constituents of the meat, varies from 2.25 to 3 per cent. of the weight of meat used, so that 1 Gm. should represent about 30 Gm., or 1 ounce represent nearly 2 pounds, of lean beef.

The fluid meat extracts, better known as meat juices or beef juices, are evidently prepared by a different process, since nearly all of them contain coagulable albumin, sometimes in considerable quantity, and varying proportions of peptone. In at least one instance the fluid also contains the finely divided residue of the dried meat.

Properties.—Extract of meat is of a brown color, usually somewhat granular, and has a pleasant odor suggestive of roasted meat, and a characteristic, distinctly saline taste. It is completely soluble in water, yielding a clear solution, which on the addition of a little table-salt has the flavor of beef-broth. When dried at 110° C. (230° F.) it loses about 20 to 22 per cent. in weight, due to moisture, and when incinerated leaves about 20 per cent. of ash.

The appearance of the fluid meat extracts or meat juices is that of a dark-red liquid, which mixes clear with cold water and in most cases becomes turbid upon heating, due to coagulation of albumin.

Constituents.—The valuable constituents of extract of meat are the nitrogenous bases: creatine, $C_4H_9N_3O_2 + H_2O$; creatinine, $C_4H_7N_3O$; xanthine, $C_5H_4N_4O_2$; hypoxanthine or sarkine, $C_5H_4N_4O$; and carnine, $C_7H_8N_4O_3 + H_2O$; in addition to which are present variable proportions of albumoses, also phosphocarnic and inosic acids, and mineral salts composed chiefly of phosphates. Only very small quantities of sodium chloride should be present. Some commercial extracts of meat have been found to contain large amounts of gelatin, which according to some authorities is desirable. The amount of nitrogen present, which is determined according to Kjeldahl's method (see NITROGEN), varies considerably; while sometimes found as low as 2.6 per cent., it should reach from 8 to 10 per cent. in extracts made from good beef. Extracts of meat have been frequently examined, and interesting papers may be found, giving the composition of commercial products, in *Proc. Am. Pharm. Assoc.*, vol. xix. p. 512, vol. xli. p. 99, vol. xlix. p. 394.

Action and Uses.—Beef extract is very extensively employed in the preparation of soups. It possesses stimulant but little nutritious properties. It may be employed during acute febrile conditions, but is of less value than fresh meat juice, because the former has been deprived of the nitrogenous elements of the flesh. Beef tea may also be used for the same purposes, and is prepared by macerating 1 pound of minced lean beef and its juice with 1 pint of tepid water for an hour, straining, bringing the strained liquid to the boiling-point and then cooling. After cooling, the fat should be removed and the tea seasoned to suit the taste.

Allied Preparations.—Beef tea or beef essence may be conveniently prepared extemporaneously as follows: Fat-free meat (beef, mutton, or chicken may be used) is cut into small pieces and put into a wide-mouth bottle with a long neck, until the bottle is nearly filled. The bottle is then closed with a sound cork and set upright in boiling water for 2 hours, in such a manner that the top of the bottle is above the surface of the water. At the end of

this time the meat is expressed and the resulting liquid is ready for use, and may be flavored with a little salt. It will keep for a short time in a cool place.

To prepare beef tea cold, Liebig proposed the following method: 60 Gm. of fat-free, finely chopped beef are added to a solution of 10 Gm. of table salt and 5 drops of hydrochloric acid in 120 Gm. of cold water; the mixture is allowed to stand for 1 hour with occasional stirring, then expressed and filtered, sufficient water being added to bring the weight of the filtrate up to 100 Gm. This preparation is also known as *Liebig's beef broth.*

EXTRACTUM CIMICIFUGÆ, *U. S.*—Extract of Cimicifuga.

Extract of black cohosh, E.; *Extrait d'actée à grappes*, Fr.; *Cimicifugaextrakt*, G.

Preparation.—Fluidextract of cimicifuga, 100 Cc.; glycyrrhiza, peeled and in No. 80 powder, a sufficient quantity. Evaporate the fluidextract of cimicifuga in a porcelain capsule, on a water-bath, at a temperature not exceeding 70° C. (158° F.), to dryness and reduce to fine powder. Add sufficient glycyrrhiza to bring the total weight up to 25 Gm.—U. S.

Extract of cimicifuga, which is admirably adapted to the pulverulent form on account of its strongly resinous character, should be preserved in tightly corked bottles in a cool dry place. It is of a brownish-yellow color, has the characteristic odor of the drug, and represents 4 times its weight of the crude drug.

Action and Uses.—See CIMICIFUGA. Dose, from 2 to 8 grains (0.12–0.50 Gm.).

EXTRACTUM CINCHONÆ.—Extract of Cinchona.

Extractum chinæ spirituosum, P. G.—*Extract of calisaya bark*, E.; *Extrait de quinquina jaune*, Fr.; *Weingeistiges Chinaextrakt*, G.; *Estratto di china*, It.

Preparation.—Extract of cinchona has been dropped from the U. S. P. The directions of the P. G. are to exhaust 1 part of coarsely powdered cinchona bark with two successive portions, of 5 parts each, of 69 per cent. alcohol by maceration for 6 and 3 days respectively, at a temperature of 15°–20° C. (59°–68° F.). The expressed fluids are mixed, set aside for 2 days, filtered, and then evaporated to dryness. When thus prepared, extract of cinchona is of reddish-brown color and forms a turbid solution with water. The P. G. demands that the alkaloidal content of this extract shall be sufficient to neutralize 5.4 Cc. of one-tenth normal acid for every Gm. of extract used in the assay.

An aqueous extract of cinchona is also recognized in the P. G. as *Extractum Chinæ Aquosum*, which is made by exhausting the coarsely powdered bark with cold water by maceration and evaporating the infusion, after filtration, to the consistence of thick honey. The requirement for alkaloidal content of this extract is slightly lower than that of the former, since 1 Gm. need neutralize but 4.6 Cc. of one-tenth normal acid in the official assay process.

Extract of cinchona, U. S. P. 1890, was prepared from yellow cinchona with a menstruum composed of alcohol 3 volumes and water 1 volume; it was of pilular consistence and if made from rich bark frequently contained from 20 to 25 per cent. of total alkaloids.

Action and Uses.—See CINCHONA. Dose, from 10 to 30 grains (0.60–2 Gm.).

EXTRACTUM COLCHICI CORMI, *U. S.*—Extract of Colchicum Corm.

Extractum colchici, Br.; *Acetic extract of colchicum*, E.; *Extrait de colchique acétique*, Fr.; *Zeitlosen-Essigextrakt*, G.

Preparation.—Colchicum corm, in No. 60 powder, 1000 Gm.; acetic acid, 350 Cc.; water, a sufficient quantity. Mix the acetic acid with 1500 Cc. of water, and, having moistened the powder with 500 Cc. of the mixture, pack it moderately in a cylindrical glass percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then water, until the colchicum corm is exhausted. Evaporate the percolate in a porcelain vessel by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence.

When assayed by the process given below, extract of colchicum corm should contain 1.4 per cent. of colchicine. If the extract should be found by assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 per cent.

Assay of Extract of Colchicum Corm.—Extract of colchicum corm, 4 Gm.; chloroform, alcohol, ether, distilled water, ammonia-water each a sufficient quantity. Dissolve the extract of colchicum corm in 20 Cc. of distilled water, carefully transfer the solution to a graduated flask, and add sufficient alcohol to make the liquid measure 100 Cc. Shake the flask well, allow it to stand for 5 minutes, filter, and collect 50 Cc. of the filtrate (representing 2 Gm. of the extract), and evaporate it to dryness in a porcelain dish by means of a water-bath. Add to the residue 10 Cc. of ether and 5 Cc. of distilled water, stir the mixture well, and heat it gently until the ether is evaporated. After cooling, pour off the aqueous solution, filtering it into a separator, retaining as much of the insoluble matter in the dish as possible. Again treat the residue with 10 Cc. of ether and 5 Cc. of water, and proceed as before; rinse the dish and filter with a little water and collect all of the aqueous liquids in the separator. Introduce a small piece of red litmus-paper into the separator, add enough ammonia-water to render the liquid alkaline, and then shake it out with three successive portions of chloroform, of 20, 15, and 10 Cc., respectively. Collect the combined chloroformic solutions in an Erlenmeyer flask, evaporate the chloroform, and add to the alkaloidal residue two successive small portions of alcohol, evaporating the alcohol each time. Now add to the residue a mixture of 5 Cc. of distilled water and 10 Cc. of ether, agitate the liquid gently and evaporate the ether, filtering the aqueous liquid into a separator. Rinse the flask with distilled water, pass the rinsing through the filter into the separator, and shake out the aqueous solution with three successive portions of chloroform, 20, 15, and 10 Cc., respectively. Collect the combined chloroformic solutions in a tared Erlenmeyer flask, evaporate the chloroform, and treat the alkaloidal residue with two successive small portions of alcohol, evaporating the alcohol each time, and dry the residue at 100° C. (212° F.) to a constant weight. The weight multiplied by 50 will give the percentage of colchicum in the extract of colchicum corm.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 12 fluidounces of the menstruum (acetic acid, 3½ volumes; water, 15 volumes).

Extract of colchicum of the Br. P. is the inspissated juice of the fresh corms. It is prepared by depriving the corms of their coats, expressing the juice, allowing the feculence to subside, decanting, heating the clear liquid to 100° C. (212° F.), straining through flannel, and evaporating at a temperature not exceeding 71° C. (160° F.) to the consistence of a soft extract.

The extract of colchicum of the French Codex is prepared from the seeds with alcohol of 60 per cent.

Action and Uses.—See COLCHICUM. Dose, from 2 to 3 grains (0.10–0.20 Gm.).

EXTRACTUM COLOCYNTHIDIS, *U. S., P. G.*—Extract of Colocynth.

Extractum colocynthidis alcoholicum. — Extrait de coloquinte, Fr.; *Koloquinthenextrakt,* G.; *Estratto di coloquintide,* It.

Preparation.—Colocynth, dried and freed from the seeds, 1000 Gm.; diluted alcohol, a sufficient quantity. Reduce the colocynth to a coarse powder by grinding or bruising, and macerate it in 3500 Cc. of diluted alcohol for 4 days, with occasional stirring; then express strongly and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour diluted alcohol upon it until the tincture and expressed liquid, mixed together, measure 5000 Cc. Having recovered from the mixture 3000 Cc. of alcohol by distillation, evaporate the residue to dryness by means of a water-bath. Lastly, reduce the dry mass to powder. Extract of colocynth should be kept in well-stoppered bottles.—U. S.

25 avoirdupois ounces of the coarsely powdered colocynth pulp should be macerated with 5½ pints of diluted alcohol for 4 days, and after expression percolated with diluted alcohol until the volume of tincture and expressed liquid, mixed together, measures 8 pints; 4½ pints of alcohol should be recovered from the mixture by distillation, and the residue evaporated to dryness and powdered.

The proportion of diluted alcohol directed by the Pharmacopœia for maceration

might be increased to 4500 Cc. (for 25 avoirdupois ounces to 7 pints) with advantage, as the experiments of Klie and others have shown; subsequent percolation should be extended correspondingly until the drug is exhausted.

Maceration and expression being considered necessary in the beginning, it would seem that the extract remaining in the press-cake could be more expeditiously obtained, and with a smaller amount of menstruum, by repeating the operation once or twice. This is the process of the German Pharmacopœia, which directs for 2 parts of colocynth, with the seeds, for the first maceration, 45 parts of alcohol, specific gravity 0.894, and for the second maceration, 15 parts each of the same alcohol and of water. With some care colocynth may be treated at once by percolation, but owing to the spongy character of its tissues it is advisable to express the absorbed liquid with a good press as soon as the greater portion of the active matter is exhausted. When the extract is made on a large scale the removal of the seeds is a tedious operation, if not impossible. For this reason the colocynth is ground, care being taken not to crush the seeds, which would load the extract with much oily matter. Dr. Squibb (1867) obtained from very dry colocynth 20.6 per cent. of extract; the general yield from the commercial article is about 14 to 14.5 per cent. The pulp alone yields usually from 30 to 40 per cent., the seeds about 5 per cent., of extract, the latter being far less bitter than the former.

Action and Uses.—See COLOCYNTH. Dose, as a purge, from 2 to 5 grains (0.12–0.30 Gm.).

EXTRACTUM COLOCYNTHIDIS COMPOSITUM, *U. S., Br.*— Compound Extract of Colocynth.

Extrait de coloquinte composé, Fr.; *Zusammengesetztes Koloquinthenextrakt*, G.

Preparation.—Extract of colocynth, 160 Gm.; purified aloes, 500 Gm.; cardamom, in No. 60 powder, 60 Gm.; resin of scammony, in fine powder, 140 Gm.; soap, dried and in coarse powder, 140 Gm.; alcohol, 100 Cc. Heat the aloes on a water-bath until it is completely melted; then add the alcohol, soap, extract of colocynth, and resin of scammony, and heat the mixture, at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous, and a thread taken from the mass appears brittle when cool. Then withdraw the heat, thoroughly incorporate the cardamom with the mixture, and cover the vessel until the contents are cool. Finally, reduce the product to a fine powder. Compound extract of colocynth should be kept in well-stoppered bottles.—U. S.

To make 4 avoirdupois ounces of compound extract of colocynth, the following formula may be used, yielding a preparation of official strength: Warm 875 grains of purified aloes, in a covered vessel on a water-bath, with 2½ fluidrachms of alcohol; add 280 grains of extract of colocynth, 245 grains each of powdered soap and resin of scammony, and heat the mixture (not above 248° F.) until it is perfectly homogeneous and brittle. Withdraw the heat, incorporate 105 grains of powdered cardamom, and cover the vessel until the contents are cold. Finally, reduce to fine powder.

Take of colocynth pulp, 6 ounces; extract of socotrine aloes, 12 ounces; resin of scammony, 4 ounces; curd soap, in shavings, 4 ounces; cardamom seeds, in fine powder, 1 ounce; alcohol (60 per cent.), 1 gallon. Macerate the colocynth in the spirit for 4 days; press out the tincture and distil off the spirit; then add the aloes, scammony, and soap, and evaporate by a water-bath until the extract is of a suitable consistence for forming pills, adding the cardamom seeds toward the end of the process.—Br.

The first formula is preferable for directing a definite amount of the extract of colocynth, instead of the extract obtained from a definite weight of colocynth pulp, which may vary considerably (see above). By mixing the ingredients in the state of fine powder a preparation uniform in appearance cannot be obtained; but by melting them together with the assistance of a little alcohol, and by subsequently drying and powdering, an unobjectionable compound extract is produced.

Action and Uses.—Compound extract of colocynth has been employed as a purge when it is desired to produce copious secretion and rapid evacuation from the bowels, and at the same time a derivative operation upon other organs. It may be employed as a revulsive in cerebral congestion and apoplexy, and is especially useful in certain mental conditions, particularly hypochondriasis and melancholia, when associated with fecal accumulations resulting from intestinal torpor. It is also a favorite remedy with many practitioners for the constipation dependent upon a sluggish portal circulation.

The drug should never be prescribed during the existence of pregnancy, and it is contraindicated in all inflammatory conditions of the intestinal tract.

It is given in the dose of from 2 to 5 grains (0.12–0.30 Gm.) as a purge. As a drastic the dose is from 5 to 20 grains (0.30–1.3 Gm.).

EXTRACTUM DIGITALIS, *U. S.*—Extract of Digitalis.

Extractum digitalis alcoholicum.—Extrait alcoolique de digitale, Fr.; *Digitalis extrakt*, G.; *Estratto di digitale*, It.; *Extracto di digitale*, Sp,

Preparation.—Fluidextract of digitalis, 100 Cc. Evaporate the fluidextract of digitalis in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.—U. S.

The yield is usually from 22 to 25 per cent. The extract is of a green-brown color, and with ordinary care retains a good consistence without having glycerin incorporated with it.

Action and Uses.—See DIGITALIS. Dose, ¼ grain (0.015 Gm.).

EXTRACTUM ERGOTÆ, *U. S.*, *Br.*—Extract of Ergot.

Extractum secalis cornuti, P. G.; *Extractum hæmostaticum.—Ergotin*, Br.; *Extrait de seigle ergoté*, Fr.; *Mutterkornextrakt*, G.

Preparation.—Ergot, in No. 40 powder, 1000 Gm.; diluted hydrochloric acid, 50 Gm.; monohydrated sodium carbonate, 8.5 Gm.; glycerin, 12.5 Gm.; alcohol, water, each a sufficient quantity. Mix alcohol and water in the proportion of 1000 Cc. of the former and 400 Cc. of the latter, and, having moistened the powder with 500 Cc. of the mixture, pack the damp powder in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the ergot is exhausted. Evaporate the percolate in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), to 250 Gm.; add 250 Cc. of water; filter when cold, washing the residue with a little water. Add the diluted hydrochloric acid to the filtrate; set aside for 24 hours; filter; wash the residue with water until the washings no longer have an acid reaction; add the washings to the filtrate; add the sodium carbonate gradually to the latter. When the evolution of carbon dioxide has ceased, evaporate the liquid to 150 Gm., add the glycerin and continue evaporation, at the temperature above named, until the weight of the extract is reduced to 125 Gm.—U. S.

The Br. P. formula is practically identical with the above, except that glycerin is not added, and evaporation is directed to be continued until a soft extract is obtained, instead of to a definite weight.

The German Pharmacopœia directs that coarsely ground ergot shall be exhausted with water by macerating twice with double its weight of cold water, for 6 hours each time. The expressed liquids are mixed, strained, and evaporated to half the weight of drug used. The residue is mixed with an equal weight of alcohol and set aside for 3 days, the mixture being frequently shaken; it is then filtered and evaporated to a soft, but non-fluid consistence. This formula corresponds to that of the French Codex.

Extract of ergot made according to the U. S. P. represents 8 times its weight of ergot and is admirably adapted for hypodermatic use, as it forms a clear solution with water and has been freed from inert matter. It is of the consistence of very thick honey and is relatively one-third stronger than the extract of the last Pharmacopœia, which was made by evaporating fluidextract of ergot to a pilular consistence. The sodium carbonate directed in the above formula is the official monohydrated variety; if the former official salt (U. S. P., 1890) containing 10 molecules of water be used, 20 Gm. will be necessary to neutralize the excess of acid. The presence of 10 per cent. of glycerin prevents the extract from drying out, and thus preserves the relation toward crude ergot.

The term *ergotin* is officially applied as a synonym for the extract in the British and French pharmacopœias.

Action and Uses.—See ERGOT. Dose, from 5 to 20 grains (0.30–1.3 Gm.).

EXTRACTUM EUONYMI, *U. S.*—Extract of Euonymus.

Extractum Euonymi Siccum—Dry Extract of Euonymus, Br.—*Extract of wahoo*, E.; *Extrait d'écorce de fusain*, Fr.; *Spillbaumrindenextrakt*, G.

Preparation.—Fluidextract of euonymus, 100 Cc.; glycyrrhiza, peeled, in No. 80 powder, a sufficient quantity. Evaporate the fluidextract of euonymus in a porcelain capsule by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), constantly stirring, to complete dryness. Reduce the residue to fine powder and add sufficient glycyrrhiza to bring the weight up to 25 Gm. Mix thoroughly.—U. S.

The dry extract of euonymus of the Br. P. is made by exhausting the bark in No. 20 powder in a percolator with 45 per cent. alcohol, evaporating the percolate to dryness, powdering the residue as far as possible, adding one-fourth of its weight of calcium phosphate, and continuing the drying and powdering until a uniform product results.

In our experience the latter process does not yield a satisfactory powder, and besides involves much tedious labor. A menstruum composed of 4 volumes of alcohol and 1 volume of water, used in making the fluidextract of euonymus, exhausts the drug of all its valuable constituents, which are resinous in character, and yields an extract readily powdered, which by addition of finely powdered licorice root may be made to retain its pulverulent condition during all seasons.

Action and Uses.—See EUONYMUS. Dose, from 1 to 8 grains (0.06–0.50 Gm.).

EXTRACTUM GENTIANÆ, *U. S., Br., P. G.*—Extract of Gentian.

Extrait de gentiane, Fr.; *Enzianextrakt*, G.; *Estratto di genziana*, It.; *Extracto di genciana*, Sp.

Preparation.—Gentian, in No. 20 powder, 1000 Gm.; water, a sufficient quantity. Moisten the powder with 400 Cc. of water and let it macerate for 48 hours; then pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the gentian. Reduce the liquid to three-fourths of its weight by boiling, and strain; then by means of a water-bath evaporate to a pilular consistence.—U. S.

25 avoirdupois ounces of gentian should be macerated with 10 fluidounces of cold water for 48 hours before being packed for percolation.

The British Pharmacopœia alone directs boiling with water for exhausting gentian root, while the United States, French, and German pharmacopœias exhaust with cold water, the albumin being removed from the infusion by boiling. The long-continued boiling directed by the U. S. P. until one-fourth of the solution has evaporated is not necessary. Cold water is preferable for exhausting gentian, since it dissolves all of the bitter principle without taking up the whole of the pectin compounds, which enter into solution in hot water. An extract prepared with the latter has a gelatinous appearance, though not in the same degree as if made by prolonged boiling with water. The yield by cold water approaches, or sometimes exceeds, 30 per cent. of the weight of the dry root, and the yellowish-brown extract yields with water a nearly clear solution.

Action and Uses.—See GENTIAN. Dose, from 1 to 8 grains (0.06–0.50 Gm.).

EXTRACTUM GLYCYRRHIZÆ, *U. S., Br.*—Extract of Glycyrrhiza.

Succus liquiritiæ, P. G.; *Extractum liquiritiæ.—Extract of licorice, Liquorice, Licorice*, E.; *Suc de réglisse, Extrait de réglisse, Sucre noir*, Fr.; *Süssholzsaft, Lakritzensaft*, G.; *Estratto di liquirizia, Sugo di liquirizia*, It.; *Regaliza en ballos*, Sp.

The U. S. and nearly all other pharmacopœias recognize the commercial extract of the root of *Glycyrrhiza glabra*, but the Br. P. does not, and instead gives a process for making an extract which somewhat resembles the purified extract of licorice of the United States.

Preparation.—For commercial purposes extract of licorice is made as follows: The root, either fresh or dried and freed from dirt, is crushed and boiled with water over a naked fire or with steam. The decoction is expressed, allowed to settle, and decanted or strained, after which the liquid is evaporated to the proper consistence. To impart firmness to the extract finely powdered licorice root, starch, and other sub-

stances are frequently added; in some of the common varieties the pulpy material from the decoction is added for the same purpose.

The Br. P. gives a process for preparing extract of licorice which consists in macerating licorice root in No. 20 powder twice with double its weight of cold distilled water. The first maceration is continued for 24 hours and the second for 6 hours. Each time the mixture is strained and expressed, the united liquids being heated to 100° C. (212° F.), strained through flannel, and evaporated to the consistence of a soft extract. Experiments of D. B. Dott (*Pharm. Jour.*, March, 1902, p. 239) have shown that this method is unsatisfactory, since the sweet principle is incompletely extracted.

While considerable extract of licorice is imported from Italy, Spain, and Greece, large quantities are also manufactured in this country, and the latter, as a rule, is of superior quality, no doubt due to improved methods and greater care. Prior to 1876 the annual importations amounted to more than 1,000,000 pounds, but they have materially decreased since then.

Description.—Extract of licorice occurs in commerce both in the form of a semi-firm mass and in sticks or rolls varying in size from $\frac{1}{4}$ inch by 4 inches to 1 inch by 8 inches, and usually stamped with the initials or name of the manufacturer or of the town where made. The former, better known as licorice mass or paste, is wholly used by tobacco manufacturers, while the drug trade consumes the rolls or sticks, which constitute by far the smaller proportion of the total quantity of extract made.

Extract of licorice in rolls has a black color, is somewhat glossy, and has a sharp conchoidal and shining fracture. Some small cavities are frequently found in the interior. The product of the different manufacturers of stick licorice differ from one another not only in size, but often by marked differences in their odor and taste; while some specimens are almost purely sweet, others are persistently acrid and empyreumatic. For medicinal purposes extract of licorice should be almost devoid of acridity.

When sticks of licorice are placed in cold water a portion is dissolved, but the residue retains the shape of the sticks. The amount soluble in cold water varies considerably, and reaches in the best brands about 70 or 75 per cent. The U. S. P. demands that not less than 60 per cent. of the extract shall be soluble in cold water, and the P. G. requires that on exhausting air-dry licorice with water of not over 50° C. (122° F.) the residue dried on a water-bath should not exceed 25 per cent., which corresponds to 75 per cent. of water-soluble matter.

Constituents.—The sweet principle is known as *glycyrrhizin*, which exists partly free and partly in combination. It is a tribasic acid, and has the composition $C_{44}H_{63}NO_{18}$. The amount of glycyrrhizin present in extract of liquorice varies from 5 to 24 per cent. For the complete extraction of glycyrrhizin a menstruum composed of 10 per cent. ammonia-water 4 volumes, alcohol 24 volumes, and water 72 volumes, has been found satisfactory. When boiled with dilute acid, glycyrrhizin splits up into glycyrrhetin, $C_{32}H_{47}NO_4$, and parasaccharic acid, $C_6H_{10}O_8$, which latter reduces Fehling's Solution. This behavior gave rise to the former view that glycyrrhizin was a glucoside. The amount of moisture in extract of licorice varies from 8 to 17 per cent., and upon ignition the extract yields from 5 to 9 per cent. of ash. A little acrid resinous matter is also present. For methods and results of analyses of extract of licorice, see *Am. Jour. Pharm.*, 1898, pages 23 and 136.

Action and Uses.—For the action and uses of Extractum Glycyrrhizæ, see EXTRACTUM GLYCYRRHIZÆ PURUM.

EXTRACTUM GLYCYRRHIZÆ PURUM, *U. S.*—Pure Extract of Glycyrrhiza.

Extrait de réglisse pur, Fr.; *Gereinigter Süssholzsaft*, G.

Preparation.—Glycyrrhiza, peeled, and in No. 20 powder, 1000 Gm.; ammonia-water, 150 Cc.; glycerin, water, of each a sufficient quantity. Mix the ammonia-water with 3000 Cc. of water, and, having moistened the powder with 1000 Cc. of the mixture, let it macerate in a closed vessel for 24 hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and then water, collecting the percolate at the rate of about 10 drops per minute, until the glycyrrhiza is exhausted. Lastly, evaporate the liquid in a porcelain capsule, by means

of a water-bath, to a pilular consistence, and while the mass is still warm incorporate with it 5 per cent. of its weight of glycerin.—U. S.

The ammonia is intended to dissolve any glycyrrhizin which may be present in the powdered root in the insoluble condition, and to prevent its becoming insoluble from the loss of ammonia during evaporation. The yield is from 16 to 20, or even 25 per cent. The extract is of a brown color and of a sweet taste; it is used for preparing Mistura Glycyrrhizæ Composita, U. S. It yields a clear solution with water, as also does the following:

Succus Liquiritiæ Depuratus, P. G.—*Purified liquorice,* E.; *Extrait de suc de réglisse,* Fr.; *Gereinigter Süssholzsaft,* G.—This preparation is extensively used in Europe, and is made by alternately placing layers of washed straw and broken licorice in a cylindrical vessel and covering the material with cold water. As the water becomes saturated it is withdrawn through a faucet below, and replaced by fresh water until but little color and taste are imparted to it. The perfectly clear liquids are then evaporated to the consistence of an extract, which should yield a clear solution with water. The yield varies from 50 to 70 per cent. For making the *Elixir e succo liquiritiæ* of the P. G., 10 parts of the above extract are dissolved in 30 parts of fennel-water, and to the solution are added 10 parts of anisated spirit of ammonia.

Action and Uses.—Extract of licorice is employed in medicine as a demulcent. It is largely used in conjunction with infusion of flaxseed in the treatment of irritable coughs, sore throat, and laryngitis. Because of its sweet taste, it is frequently employed for the purpose of disguising the taste of nauseating drugs.

EXTRACTUM HÆMATOXYLI, *U. S.*—Extract of Hematoxylon.

Extractum ligni campechiani.—Extract of logwood, E.; *Extrait de bois de Campêche,* Fr.; *Campecheholzextrakt,* G.

Preparation.—Hematoxylon, rasped, 1000 Gm.; water, 1000 Cc. Macerate the hematoxylon with the water for 48 hours. Then boil, avoiding the use of metallic vessels, until one-half of the water has evaporated; strain the decoction while hot, and evaporate to dryness.—U. S.

25 avoirdupois ounces of rasped logwood should be macerated with 2 gallons of water for 48 hours, and then boiled, as directed above.

The medicinal value of logwood lies in its astringent principle, which cannot be entirely extracted with cold water; hence boiling is directed. It is important that all contact with metal be avoided on account of the tannin. The yield is about 12 per cent., occasionally as low as 6 per cent. Extract of hematoxylon is well adapted for the dry condition, as it is non-hygroscopic. Its taste is sweetish and afterward astringent, and it should yield a clear, purplish-red solution with water. The extract is prepared on a large scale for use in the arts, but the commercial article sold in boxes is not suitable for medicinal purposes, being only partly soluble in cold water.

Action and Uses.—This extract preserves the properties of logwood, and may be employed as a convenient substitute for the latter. The dose is 10 grains (0.60 Gm.).

EXTRACTUM HYOSCYAMI, *U. S., P. G.*—Extract of Hyoscyamus.

Extractum Hyoscyami Viride—Green Extract of Hyoscyamus, Br. *Extract of henbane,* E.; *Extrait de feuilles de jusquiame,* Fr.; *Bilsenkrautextrakt,* G.; *Estratto di guisquiamo,* It.

Preparation.—Fluidextract of hyoscyamus, 100 Cc. Evaporate the fluidextract of hyoscyamus in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence. When assayed by the method given below, extract of hyoscyamus should be found to contain 0.3 per cent. of total alkaloids. If the extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 0.3 per cent.

Assay of Extract of Hyoscyamus.—Extract of hyoscyamus, 10 Gm.; alcohol, ammonia-water, distilled water, chloroform, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin or iodeosin test-solution,

of each a sufficient quantity. Weigh into a small dish 10 Gm. of extract of hyoscyamus and dissolve it in a mixture containing alcohol 5 Cc., distilled water 10 Cc., ammonia-water 2 Cc., and chloroform 20 Cc. When dissolved, transfer it to a separator, rinsing the beaker with a little alcohol. Cork the separator, and shake for 2 minutes. Draw off the chloroformic layer into a second separator, and add to the contents of the first separator 10 Cc. more of chloroform. Shake for several minutes, allow to separate, and again draw off the chloroformic layer into the second separator. Repeat this with 10 Cc. more of chloroform. To the united chloroformic solutions in the second separator add 5 Cc. of normal sulphuric acid and 10 Cc. of distilled water, and shake for several minutes. Draw off the chloroformic layer after the liquids have separated into a clean separator, and the aqueous fluid into a beaker, and repeat the process by adding to the chloroformic fluid 10 Cc. of distilled water and 1 Cc. of normal sulphuric acid. Draw off the chloroformic layer, rejecting the same, and then draw the acid fluid into the beaker. Filter the combined acid aqueous solutions in the beaker through a pledget of cotton wool into a clean separator, washing the last separator, the beaker, and the funnel with about 10 Cc. of distilled water. To the first separator add 15 Cc. of chloroform, a small piece of red litmus-paper, and sufficient ammonia-water to produce a distinctly alkaline reaction. Shake for 2 minutes, and when the liquids have separated, draw off the chloroformic layer into a beaker. Repeat this process twice with 10 Cc. more of chloroform, and evaporate the combined chloroformic extracts in the beaker to dryness on a moderately warm water-bath. Dissolve the residual alkaloids in 5 Cc. of tenth-normal sulphuric acid and titrate the excess of acid with fiftieth-normal potassium hydroxide solution, using 5 drops of the hematoxylin or iodeosin test-solution as indicator. Divide the number of Cc. of fiftieth-normal potassium-hydroxide solution used by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.0287, and this product by 10, to obtain the percentage of mydriatic alkaloids contained in the extract of hyoscyamus.—U. S.

The extract has an olive-green color and the heavy odor of hyoscyamus. The leaves yield from 20 to 25 per cent. of extract. The alkaloidal content of the leaves being quite variable and at times very inferior, the resulting extract will at times prove unsatisfactory unless it has been standardized.

Green Extract of Hyoscyamus of the Br. P. is the inspissated juice of fresh leaves, flowering tops, and young branches. It is prepared by the general method given on page 590, the yield being from 2.5 to 4 per cent. No alkaloidal standard is required.

The extract of hyoscyamus of the P. G. is an alcoholic extract of the inspissated juice of fresh hyoscyamus herb, prepared exactly like the corresponding extract of belladonna (see page 594). This extract is required to contain about 0.75 per cent. of the alkaloids of henbane.

Action and Uses.—See HYOSCYAMUS. Dose, from 1 to 2 grains (0.06–0.12 Gm.).

EXTRACTUM JALAPÆ, *Br.*—Extract of Jalap.

Extrait de jalap, Fr.; *Jalapenextrakt*, G.

Preparation.—Jalap, in coarse powder, 1 pound; alcohol (90 per cent.), 4 pints; distilled water, 1 gallon. Macerate the jalap in the spirit for 7 days, press out the tincture, then filter, and distil off the spirit, leaving a soft extract. Again macerate the residual jalap in the water for 4 hours, express, strain through flannel, and evaporate on a water-bath to a soft extract. Mix the two extracts and evaporate, at a temperature not exceeding 60° C. (140° F.), to the consistence of a firm extract.—Br.

No advantage whatever results from treating jalap with water after it has been exhausted by alcohol. 240 grains of such an aqueous extract were taken by A. B. Taylor (1864) in the course of 8 hours without producing any noticeable effect. Alcohol alone will yield between 12 and 18 or 22 per cent. of active extract, and cold water will subsequently extract 30 to 35 per cent. of inert matter.

Extract of jalap has been dropped from the U. S. P., and we think very properly, since there was little difference between the official resin of jalap and the former extract, except that the latter contained a small proportion of water-soluble matter, which is removed in the manufacture of the resin. Official alcohol was used in the preparation of the former extract, the resulting percolate being evaporated to a pilular consistence.

Action and Uses.—Extract of jalap is preferred by many to the powdered drug, because of its concentration. It possesses all the properties of JALAPA (which see). The dose is from 5 to 15 grains (0.30–1 Gm.).

EXTRACTUM KRAMERIÆ, *U. S., Br.*—Extract of Krameria.

Extractum ratanhiæ.—Extract of rhatany, E.; *Extrait de ratanhia*, Fr.; *Ratanhiaextrakt*, G.

Preparation.—Krameria, in No. 40 powder, 1000 Gm.; water, a sufficient quantity. Moisten the powder with 300 Cc. of water, pack it in a conical glass percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the astringency of the krameria. Heat the liquid to the boiling-point, strain, and by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), evaporate to dryness.—U. S.

25 avoirdupois ounces of krameria should be moistened with about 7½ fluidounces of water before being packed in a percolator.

The processes of the other pharmacopœias are practically identical with this, but the Br. P. and Fr. Cod. order distilled in place of common water.

It is important that the root be exhausted with *cold* water. Hot water will yield about 5 or 6 per cent. more extract, which, however, is but incompletely soluble in water, while the official extract yields a somewhat turbid solution with warm water, but a clear solution in the presence of sugar. The amount of extract obtainable depends on the size and the variety of rhatany-root used, the woody part of which contains but little soluble matter. The smaller branches of Peruvian rhatany yield about 12 per cent. of *dry* extract, but the thick main root yields only 5 or 6 per cent.; Savanilla and Para rhatany give a larger yield, about 12 to 18 per cent. The extract is of a red-brown color, glossy, resembling kino in appearance, and is not hygroscopic. Iron utensils must not be used in its preparation.

Action and Uses.—Extract of krameria is employed in all cases in which the drug itself is indicated. The dose is from 5 to 20 grains (0.30–1.3 Gm.).

EXTRACTUM LEPTANDRÆ, *U. S.*—Extract of Leptandra.

Extrait de leptandra, Fr.; *Leptandraextrakt*, G.

Preparation.—Fluidextract of leptandra, 100 Cc.; glycyrrhiza, peeled, in No. 80 powder, a sufficient quantity. Evaporate the fluidextract of leptandra in a porcelain capsule, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), constantly stirring, to complete dryness. Reduce the residue to fine powder and add sufficient glycyrrhiza to bring the weight up to 25 Gm. Mix thoroughly.—U. S.

Powdered extract of leptandra must be kept in well-stoppered bottles in a dry cool place to avoid caking. With diluents other than licorice root the results are unsatisfactory, the powder soon showing a disposition to cake, especially in warm weather. The extract has a blackish-brown color and a very bitter taste, and represents 4 times its weight of the crude drug.

Action and Uses.—The uses of this extract are fully described under LEPTANDRA (which see). The dose is from 2 to 5 grains (0.12–0.30 Gm.).

EXTRACTUM MALTI, *U. S.*—Extract of Malt.

Essence (Extrait) de malt, Fr.; *Malzextrakt*, G.

Preparation.—Malt, in coarse powder, not finer than No. 12, 1000 Gm.; water, a sufficient quantity. Upon the powder, contained in a suitable vessel, pour 1000 Cc. of water, and macerate for 6 hours. Then add 4000 Cc. of water heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceeding 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath or vacuum-apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid rapidly to the consistence of thick honey. Keep the product in well-closed vessels in a cool place.—U. S.

In making this extract it is of the utmost importance that the temperature should never exceed 65° C. (149° F.), and it is safer, for the preservation of the diastase, to keep it at or below 55° (131° F.) until the starch of the malt has been converted into glucose and dextrin. According to Payen and Persoz, good malt contains 2 per cent. of diastase, and since 1 part of this compound is estimated to convert 2000 parts of starch, it is obvious that properly prepared malt extract should contain nearly the entire amount

of diastase which was originally present in the malt. This is only accomplished by the rapid evaporation of the infusion at a temperature which does not act injuriously upon diastase, as is directed in the above process. The yield is from 65 to 75 per cent.

Properties.—Extract of malt is a brown-yellow or light amber-colored, thick liquid or semifluid mass, having a slight peculiar odor, a sweet mucilaginous taste, and a distinct acid reaction to litmus-paper. It dissolves in water in all proportions, yielding a nearly transparent solution, in which alcohol produces a milky turbidity, after a short time becoming clear, with the separation of a flocculent precipitate. The aqueous solution also yields precipitates with picric acid, tannin, most alkaloidal reagents, and mercuric chloride and other metallic salts. When the extract is added to starch-paste, this is gradually liquefied, and will finally not acquire a blue color on the addition of iodine solution. On heating the extract it is decomposed, giving off the odor of burning sugar, and finally leaving a small amount of ash.

Constituents.—Good extract of malt contains 20 to 25 per cent. of water, 48 to 70 of maltose, 2 to 16 of dextrin, 0.3 to 0.4 of phosphoric acid, and 0.75 to 1.5 of lactic acid.

Valuation.—The value of extract of malt resides in the maltose and diastase present. For method of analysis, see article by J. F. C. Jungk in *Amer. Pharm. Jour.*, June, 1883, p. 289. The diastasic value of extract of malt is determined by its power of converting starch into dextrose. The following method is recommended for comparative testing of malt extracts: dissolve 5 Gm. of extract of malt in sufficient distilled water to yield 100 Cc. of solution; of this, add 5 Cc., representing 0.25 Gm. of the extract, to 250 Cc. of cold starch mucilage (prepared by dissolving 30 Gm. of Bermuda arrow-root in 1000 Cc. of boiling distilled water) and keep the mixture at a temperature of 55° to 60° C. (131°–140° F.) for 30 minutes; then stop the diastasic action by raising the temperature to 100° C. (212° F.) or by addition of 2 or 3 Cc. of a 10 per cent. sodium hydroxide solution, and dilute the mixture to a given volume by addition of water. Titrate an aliquot part of the liquid with Fehling's Solution (alkaline cupric tartrate volumetric solution, U. S. P.) and ascertain the amount of dextrose present, from which deduct the amount found in a corresponding amount of the extract of malt by previous titration with Fehling's Solution; the difference indicates the amount of sugar produced by the diastase present in the extract. Each Cc. of Fehling's Solution corresponds to 0.005 Gm. of anhydrous dextrose, or 0.0045 Gm. of starch converted thereinto.

According to Jungk, properly prepared extract of malt should convert its own weight of starch into dextrose at 16.6° C. (62° F.) in 40 minutes, or at 37.8° C. (100° F.) in 10 minutes. Some commercial malt extracts are scarcely superior to glucose; others consist of a stronger or weaker beer.

Pharmaceutical Uses.—Extract of Malt is serviceable in emulsionizing cod-liver oil and as a vehicle for various remedial agents.

Action and Uses.—Extract of malt has been largely employed by the laity as a general tonic. It is employed by some physicians for the purpose of increasing the milk of nursing women, and as a stimulant tonic during convalescence from acute infectious diseases.

EXTRACTUM NUCIS VOMICÆ, *U. S., Br.*—Extract of Nux Vomica.

Extractum strychni, P. G.; *Extractum nucum vomicarum spirituosum.—Extrait de noix vomique*, Fr.; *Brechnussextrakt, Strychnossamenextrakt, Krähenaugenextrakt*, G.; *Estratto di noce vomica*, It.

Preparation.—Nux vomica, in No. 20 powder, 1000 Gm.; acetic acid, water, alcohol, sugar of milk, dried and in fine powder, each a sufficient quantity. Mix 500 Cc. of acetic acid with 1300 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then water, until the percolate passes but faintly imbued with bitterness, or the nux vomica is exhausted. Reserve the first 750 Cc. of the percolate and, having heated the remainder to boiling,

filter, and evaporate the filtrate to a soft extract; dissolve this in the reserved portion, and add enough water to make the liquid measure 900 Cc. To the liquid thus obtained add 3000 Cc. of alcohol, shake the mixture well, and set it aside for 24 hours, with occasional agitation. Filter the liquid through paper, and wash the residue in the filter with a mixture of alcohol 3 volumes and water 1 volume, until the washings are only faintly bitter. Evaporate the filtrate and washings in a porcelain dish, on a water-bath, to dryness. Determine, by the method given below, the percentage of strychnine in the dry extract; ascertain, by calculation, the amount of strychnine in the remainder of the extract, add to this enough well-dried sugar of milk to bring the quantity of strychnine in the final dry extract of nux vomica to 5 per cent.; and, when thoroughly powdered and mixed, transfer the extract to small, well-stoppered vials.

Extract of nux vomica, when assayed by the following process, should be found to contain 5 per cent. of strychnine.

Assay of Extract of Nux Vomica.—Extract of nux vomica, 2 Gm.; distilled water, ether, chloroform, ammonia-water, normal sulphuric acid, sulphuric acid solution (3 per cent.), nitric acid (specic gravity, 1.40), sodium hydroxide solution (1 in 10), tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, iodeosin test-solution, each a sufficient quantity. Introduce the extract of nux vomica into a beaker, and dissolve it in 25 Cc. of a mixture of 16 Cc. of ether, 5 Cc. of chloroform, and 4 Cc. of ammonia-water. When dissolved, transfer it to a separator, rinsing the beaker with a little chloroform, and adding the rinsings to the separator. Insert the stopper securely and shake the separator carefully for a few minutes. Draw off the aqueous layer into another separator, washing the ether solution and separator with a little water, and adding this to the second separator. Then shake out the aqueous liquid with two portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a few drops of the liquid left in the second separator still give a reaction with mercuric potassium iodide test-solution after acidulating, repeat the shaking out with 10 Cc. more of chloroform. Now shake out the chloroformic solution in the first separator with three portions of 15, 10, and 10 Cc. each of sulphuric acid (3 per cent.), and collect the combined acid solutions in another separator. Introduce a small piece of red litmus-paper, add enough ammonia-water to render the liquid alkaline, and extract the mixture with three portions, respectively, of 15, 10, and 10 Cc. each of chloroform. Draw off the chloroformic solutions into a beaker, and evapornte the chloroform with the aid of a water-bath. Dissolve the alkaloidal residue in the beaker in 15 Cc. of 3 per cent sulphuric acid solution by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cooled mixture of equal parts of nitric acid (specific gravity, 1.40) and distilled water, and after rotating the liquid a few times, set it aside for exactly 10 minutes, shaking it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10), and wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid be not quite turbid, add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a beaker. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the beaker, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue add 10 Cc. of tenth-normal sulphuric acid, 5 drops of iodeosin test-solution, about 90 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved titrate the excess of acid with fiftieth-normal potassium hydroxide solution until aqueous liquid just turns pink. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 10 (the 10 Cc. of tenth-normal sulphuric acid used), multiply the remainder by 0.033, and this product by 50, which will give the percentage of strychnine contained in the extract of nux vomica.—U. S.

The preparation of extract of nux vomica with an acid aqueous menstruum avoids the extraction of fixed oil and subsequent removal of the same in making the powdered extract. The addition of alcohol to the concentrated aqueous percolate is made for the purpose of precipitating certain inert matters taken up by the aqueous menstruum. The assay process is that suggested by H. M. Gordin (*Proc. Amer. Pharm. Assoc.*, 1902), and is a modification of the method first proposed by Gerock in 1889.

Extract of nux vomica of the Br. P. is made from a standardized hydro-alcoholic liquid extract by direct evaporation. Since the Br. liquid extract of nux vomica must contain 1.5 Gm. of strychnine in 100 Cc., 100 Cc. of the same should upon evaporation and admixture of sugar of milk yield an extract weighing 30 Gm. and containing 5 per

cent. of strychnine, the amount officially required. The exact quantity of sugar of milk necessary for a given volume of the liquid extract is determined by evaporating 50 Cc. of the latter to a firm extract and then subtracting the weight of the firm extract from 15, the difference indicating the weight of sugar of milk to be added to every 50 Cc. of liquid extract used. The final product is directed to be in the form of a firm extract.

The German Pharmacopœia directs exhaustion of the nux vomica with alcohol of 68.5 per cent. by volume, while the Fr. Codex orders maceration with 80 per cent. alcohol. The former recognizes a dry extract containing not less than 17 per cent. of total alkaloids, whereas the French extract is of pilular consistence and not standardized.

Action and Uses.—The employment of this extract is identical with that of NUX VOMICA (which see). It forms a convenient method for administration in pill form. Dose, from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.).

EXTRACTUM OPII, *U. S., Br., P. G.*—Extract of Opium.

Extractum thebaicum.—Extrait d'opium, Extrait thebaïque, Fr.; *Opiumextrakt,* G.; *Estretto di oppio acquosa,* It.

Preparation.—Powdered opium, 100 Gm.; sugar of milk, recently dried and in fine powder, water, each a sufficient quantity. Place the powdered opium in a mortar and rub into a smooth paste with 250 Cc. of water; then transfer to a flask or bottle, wash the mortar with 750 Cc. of water in successive portions, and add the washings to the contents of the flask or bottle. Cork the flask or bottle, and shake vigorously every hour or two during 12 hours. Then filter through a rapidly acting double filter, and percolate the magma on the filter slowly with water until the filtrate passes nearly colorless and only faintly bitter.

Concentrate the filtrate and washings in a tared capsule, on a water-bath, until the residue weighs about 200 Gm. and allow it to become cold. Then determine the weight exactly, transfer 12 Gm. of it to an Erlenmeyer flask having a capacity of about 100 Cc., and determine in this portion the amount of morphine by the process of assay given below, using the quantities of liquids there directed for 4 Gm. of the dry extract. In another portion of 5 Gm. determine the amount of water by drying it in a flat-bottomed capsule, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained ascertain, by calculation, the amount of morphine and of water contained in the remainder of the extract, add to this sufficient well-dried sugar of milk to bring the quantity of morphine in the final dry extract to 20 per cent., then evaporate the whole to dryness, reduce it to powder, and transfer it to small, well-stoppered vials.

Assay of Extract of Opium.—Extract of opium, dried at 100° C. (212° F.), 4 Gm., ammonia-water, 2.2 Cc.; alcohol, ether, water, lime-water, each a sufficient quantity. Dissolve the extract of opium in 30 Cc. of water, filter the solution through a small filter, and wash the filter and residue with water until all soluble matters are extracted, collecting the washings separately. Evaporate, in a tared capsule, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 10 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 15 Gm. Then add 7 Gm. (8.5 Cc.) of alcohol, shake well, add 20 Cc. of ether, and shake again. Now add the ammonia-water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during 10 minutes, and then set it aside, in a moderately cool place, for at least 6 hours, or over night.

Remove the stopper carefully, and should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly acting filters, of a diameter of 7 Gm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-water, and afterward wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, dis-

place the remaining alcohol by ether, using about 10 Cc. or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them.

Transfer the crystals (which are not quite pure) to an Erlenmeyer flask, add lime-water in the proportion of 10 Cc. for each 0.1 Gm. of morphine, and shake the flask at intervals for 25 minutes. Filter through two counterpoised, rapidly acting, plainly folded filters, one within the other (the triple fold of the inner filter being laid against the single fold of the outer filter). Rinse flask with more lime-water and wash filter with the same fluid until filtrate, after acidulating, yields no more precipitate with Mayer's Solution. Press the filters until nearly dry between bibulous paper and dry them to constant weight, counterpoising with outer filter, and weigh. Deduct the weight of the insoluble matter on the filter from the weight of the impure morphine previously found, and the difference, multiplied by 25, represents the percentage of pure crystallized morphine contained in the extract of opium.—U. S.

Four avoirdupois ounces of opium may be macerated with 2½ pints of cold water during 12 hours with frequent trituration, and then exhausted on a filter as directed; the filtrate should be concentrated to 8 avoirdupois ounces, allowed to become cold, and then assayed.

The pharmacopœias agree in ordering cold water for the extraction of crude opium; only the U. S. P. and the P. G. direct the use of powdered opium and common water, the other authorities directing distilled water. The manipulation does not differ materially except in the number of macerations and the proportion of water used. For 1 part of opium 2 macerations are directed with 8 and 4 parts, Fr. Cod. (with 5 and 2½ parts, P. G.), of water; 3 macerations each with 2½ parts of water, Br., and 1 maceration with 10 parts of water, U. S. The macerations should be effected at a low temperature, say about 60° F. At a higher temperature a larger amount of extract is obtained, more largely contaminated with narcotine and other principles, and of an inferior quality.

The U. S. and German extracts are in dry form, while the British and French extracts are of pilular consistence. The amount of extractive matter yielded by opium to water varies from 40 to 60 per cent., and hence the great desirability of a standardized extract. The U. S. and Br. pharmacopœias both demand 20 per cent. of morphine in the extract, and the German requires not less than 17 per cent.

The necessary amount of sugar of milk to be added to the soft extract to bring the final product up to the official standard may be readily ascertained. Suppose the soft residue is found to contain 70 per cent. of moisture and 7 per cent. of morphine, then every 10 Gm. (or grains) of residue require the addition of 0.5 Gm. (or grain) of sugar of milk before final evaporation to dryness. The final product will weigh 3.5 Gm. (or grains), containing 0.7 Gm. (or grains) of morphine, which is equivalent to 20 per cent.

Extractum Opii Liquidum.—*Liquid Extract of Opium*, Br.—The British Pharmacopœia recognizes a liquid extract of opium, which is prepared in the following manner: Mix 18.75 Gm. of extract of opium with 400 Cc. of distilled water; set aside for an hour, stirring frequently; add 100 Cc. of 90 per cent. alcohol; set aside in a cool place for 24 hours and then filter. The product should measure 500 Cc. and have a specific gravity of 0.985 to 0.995. When assayed by the method given under TINCTURE OF OPIUM the above liquid extract of opium should yield an amount of morphine, reckoned as anhydrous, corresponding to not less than 0.7 Gm. nor more than 0.8 Gm. in 100 Cc.

Each Imperial fluidounce of liquid extract of opium represents 16⅔ grains of extract of opium, or 20 Cc. represent 0.75 Gm.—Br.

Action and Uses.—Extract of opium possesses no advantages over the powdered drug, except that it is given in smaller quantities and is less liable to cause nausea and vomiting, headache, and insomnia. The dose is from ¼ to ½ grain (0.015–0.03 Gm.).

EXTRACTUM PHYSOSTIGMATIS, *U. S., Br.*—Extract of Physostigma.

Extractum fabæ Calabaricæ.—Extrait de fève de Calabar, Fr.; *Kalabarbohnenextrakt, Physostigmaextrakt,* G.

Preparation.—Physostigma, in No. 80 powder, 1000 Gm.; alcohol, glycyrrhiza, peeled, in No. 80 powder, each a sufficient quantity. Moisten the physostigma with 400 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 3000 Cc. of tincture are obtained, or the physostigma is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 100 Cc.; mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, on a water-bath, to dryness. Remove 1 Gm. of the extract, and assay this by the process given below; from the results thus obtained ascertain, by calculation, the amount of ether-soluble alkaloids contained in the remainder of the extract. Add to this enough glycyrrhiza to bring the quantity of alkaloids in the finished extract to 2 per cent.; reduce to powder, mix thoroughly, and transfer it at once to well-stoppered vials.

Extract of physostigma, when assayed by the following process, should be found to contain 2 per cent. of ether-soluble alkaloids:

Assay of Extract of Physostigma.—Extract of physostigma, 1 Gm.; alcohol, ether, 5 per cent. sodium bicarbonate solution, normal sulphuric acid, distilled water, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, iodeosin test-solution, each a sufficient quantity. Dissolve the extract of physostigma in as little diluted alcohol as possible in a porcelain dish, and then add about 5 Gm. of pure, clean, sharp-quartz sand, and evaporate to dryness on a water-bath, rubbing carefully with a pestle so as to get the extract thoroughly distributed over the sand. When dry, transfer the entire contents of the dish to a flask, add 100 Cc. of ether, cork well, and shake thoroughly for several minutes. Then add 20 Cc. of a 5 per cent. sodium bicarbonate solution, and shake vigorously at intervals for 1 hour. Let settle and decant 50 Cc. of the ethereal solution into a separator, and add 10 Cc. of distilled water and sufficient normal sulphuric acid to make the liquid acid. Shake well for 5 minutes and draw off the aqueous layer into another separator. Repeat the extraction, using 5 Cc. each of normal sulphuric acid and distilled water, and adding the acid aqueous layer to the contents of the second separator. Finally, repeat again, using 1 Cc. of normal sulphuric acid and 9 Cc. of distilled water, and draw this off also into the second separator. To the combined acid liquids in the second separator add 25 Cc. of ether and sufficient 5 per cent. sodium bicarbonate solution to make the liquid alkaline. Shake for a few minutes, let separate, and transfer the ether into a beaker. Repeat with 20 Cc., and again with 15 Cc. more of ether added to the aqueous fluid in the separator, shake for 2 minutes, let separate, and transfer the ethereal liquid to the beaker. Evaporate the ether from the combined solutions in the beaker carefully on a water-bath, and when dry dissolve the residue in 2 Cc. of tenth-normal sulphuric acid; rinse the solution into a 100 Cc. flask with distilled water, add enough distilled water to bring the volume to about 40 Cc., add 15 Cc. of ether, and, having shaken the flask, add 5 drops of iodeosin test-solution, then titrate the excess of acid with fiftieth-normal potassium hydroxide solution, until, after shaking, the aqueous liquid just acquires a pink color. Divide the number of Cc. of fiftieth-normal solution used by 5, subtract the quotient from 2 (the 2 Cc. of tenth-normal sulphuric acid taken), and multiply the remainder by 0.0273, and this product by 200; the result will be the percentage of ether-soluble alkaloids contained in the extract of physostigma.—U. S.

Extract of physostigma, thus prepared, should be kept in amber-colored bottles protected against light.—U. S.

The Br. P. directs the exhaustion of calabar bean with 90 per cent. alcohol, percolation being preceded by maceration in a closed vessel with an equal weight of the menstruum. The alcohol is recovered by distillation, and the residue evaporated to a very soft extract, which is then mixed with 3 times its weight of milk sugar to form a firm extract.

On account of the considerable amount of fat in the calabar bean, it is impossible to produce a perfect pilular or powdered extract without the addition of some diluent. Milk sugar in the proportion directed in the Br. P. answers for a firm extract, but a more absorptive substance is required for the powdered article. In our experience the

use of glycyrrhiza yields a very satisfactory product, which has kept well for nearly two years.

While the powdered extract of the U. S. P. is standardized to a definite alkaloidal strength, the British extract bears no relation either to the crude drug or its alkaloid content; moreover, the latter extract is about one-fourth as strong as that of the Br. P. of 1885.

Action and Uses.—The properties and uses of this drug are fully described under PHYSOSTIGMA (which see). The dose is from $\frac{1}{12}$ to $\frac{1}{8}$ of a grain (0.005–0.008 Gm.).

EXTRACTUM QUASSIÆ, *U. S.*—Extract of Quassia.

Extrait de quassie (bois amer), Fr.; *Quassiaextrakt*, G.; *Estratto di quassia acquosa*, It.

Preparation.—Quassia, in No. 20 powder, 1000 Gm.; water, sugar of milk, recently dried and in fine powder, each a sufficient quantity. Moisten the quassia with 400 Cc. of water, pack it firmly in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with bitterness. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then evaporate, by means of a water-bath, to dryness, and add sufficient sugar of milk to bring the total weight up to 100 Gm. Mix thoroughly and reduce the extract to fine powder.—U. S.

Although the present extract of quassia is much weaker than the pilular extract of the preceding pharmacopœia, it is to be preferred for dispensing purposes. Pilular extract of quassia becomes very tough in the course of time. Exhausted with cold water, quassia yields from 3 to 5 per cent. of extractive, which yield may be more than doubled if boiling water be used, but the resulting extract has a jelly-like appearance. Diluted alcohol also increases the yield of extract, but the resulting product does not give a clear solution with water. Powdered extract of quassia represents 10 times its weight of crude drug, and may conveniently be administered in pills or in the dry form in capsules.

Action and Uses.—Extract of quassia is employed as a simple bitter, usually in conjunction with other remedies, such as iron and quinine. The dose is from 1 to 3 grains (0.06–0.20 Gm.).

EXTRACTUM RHAMNI PURSHIANÆ, *U. S.*—Extract of Rhamnus Purshiana.

Extractum Cascaræ Sagradæ—Extract of Cascara Sagrada, Br.—*Extrait de cascara sagrada*, Fr.; *Cascara Sagrada-Extrakt, Amerikanisch Faulbaumrindenextrakt*, G.

Preparation.—Rhamnus purshiana, in No. 60 powder, 1000 Gm.; alcohol, water, glycyrrhiza, peeled, in No. 80 powder, each a sufficient quantity. Mix 125 Cc. of alcohol with 875 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed at the rate of about 5 drops per minute, gradually adding menstruum, using the same proportions of alcohol and water as before, until the tincture passes tasteless and the drug is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to the consistence of syrup. Mix this with the reserved portion and continue the evaporation, at or below the above-mentioned temperature, to dryness. Reduce the extract to fine powder, and add sufficient glycyrrhiza to bring the weight of the mixture up to 250 Gm. Mix thoroughly.—U. S.

The British Pharmacopœia directs that cascara sagrada in No. 20 powder be moistened with distilled water and allowed to soften during a few hours; it is then placed loosely in a percolator and percolated with more distilled water until exhausted. The infusion is finally evaporated on a water-bath to dryness.

Cascara sagrada yields to water and to weak alcohol somewhat less than 25 per cent. of dry extractive. The latter menstruum has the advantage of preventing fermentative changes during the prolonged contact with the drug, especially in warm weather.

The powdered extract is of a yellowish- to reddish-brown color and has the characteristic bitter taste of the drug. It keeps admirably in all seasons. If made with cold or even with boiling water, the color of the extract is grayish brown, devoid of all yellow and red.

Action and Uses.—This extract is employed principally as a laxative. Its properties and uses are fully described under RHAMNUS PURSHIANA (which see). The dose is from 2 to 8 grains (0.12–0.50 Gm.), given once or twice daily.

EXTRACTUM RHEI, *U. S., Br., P. G.*—Extract of Rhubarb.

Extractum rhei alcoholicum.—Extrait de rhubarbe, Fr.; *Rhabarberextrakt,* G.; *Estratto di rabarbaro,* It.

Preparation.—Fluidextract of rhubarb, 100 Cc. Evaporate the fluidextract of rhubarb in a porcelain capsule by means of a water-bath, constantly stirring, at a temperature not exceeding 50° C. (122° F.), to a pilular consistence.—U. S.

The Br. P. directs rhubarb in No. 20 powder to be macerated for 48 hours with 60 per cent. alcohol, and then percolated with the same menstruum until exhausted. The resulting tincture is evaporated to dryness. The P. G. directs a menstruum of alcohol 2 parts and water 3 parts with maceration for 24 hours. This process is repeated and the united infusions set aside for 2 days, then filtered, and evaporated to dryness. French extract of rhubarb is made with cold distilled water.

The amount of extractive obtainable from rhubarb depends upon the quality of the drug and the menstruum employed. Good commercial rhubarb has been found to yield, with the U. S. menstruum, from 30 to 40 per cent. of dry extractive. Extract of rhubarb is well adapted for the pulverulent form, as it remains in that condition almost indefinitely if prepared as directed above. It is equally useful for exhibition in pill or powder form, and is to be preferred to the pilular extract, which has a tendency to become hard and tough. The official extract is of a yellowish-brown color and has the decided odor of rhubarb and a bitter taste.

Extractum Rhei Compositum, P. G.—Extract of rhubarb, 30 parts; extract of aloes, 10 parts; resin of jalap, 5 parts; and soap, 20 parts; triturate together, moisten with diluted alcohol, mix well, and dry. It is of a blackish-brown color, and is also known as *Extractum catholicum s. panchymagogum.*

Action and Uses.—Extract of rhubarb is in many cases less effective as a purge than the powdered drug. It may be employed for the same purposes as RHEUM (which see). The dose is from 5 to 10 grains (0.3–0.60 Gm.).

EXTRACTUM SCOPOLÆ, *U. S.*—Extract of Scopola.

Extrait de racine de scopola, Fr.; *Skopolawurzelextrakt,* G.

Preparation.—Fluidextract of scopola, 100 Cc. Evaporate the fluidextract of scopola in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.

When assayed by the method given under EXTRACT OF BELLADONNA LEAVES, extract of scopola should contain 2 per cent. of mydriatic alkaloids. If the extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 2 per cent.—U. S.

Scopola extract appears for the first time in the U. S. P. It was introduced for the purpose of permitting its use in plasters, being almost identical in composition and medicinal effect with the extract of belladonna root. Scopola offers an advantage over belladonna root in containing fully as much alkaloid and in being more uniform in the proportion present. The yield of the extract equals about 16 or 20 per cent., the color being light brown.

Action and Uses.—For the action and uses of Extractum Scopolæ, see BELLADONNA. Dose, $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.).

EXTRACTUM STRAMONII, *U. S.*—Extract of Stramonium.

Extrait de feuilles de stramoine, Fr.; *Stechapfelblätterextrakt*, G.

Preparation.—Fluidextract of stramonium, 100 Cc. Evaporate the fluidextract of stramonium in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.

When assayed by the method given under EXTRACT OF BELLADONNA LEAVES, extract of stramonium should contain 1.4 per cent. of mydriatic alkaloids. If the extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 per cent.—U. S.

Extractum Stramonii of the Br. P. (*Extractum Stramonii Seminis*, U. S., 1890) is made from the seed of the stramonium plant by reducing the same to No. 40 powder, and exhausting by slow percolation with 70 per cent. alcohol. Most of the alcohol is recovered by distillation, after which the residual liquid is evaporated to the consistence of a firm extract. On account of the large amount of fixed oil in stramonium seed, the U. S. P. of 1890 directed the use of diluted alcohol as a menstruum, but even with this change extract of stramonium seed is an unsatisfactory preparation. Moreover, it has been shown that the leaves of stramonium contain more alkaloid than the seed, and hence the extract has been dropped from the 1900 edition of the U. S. P.

The yield of extract of stramonium leaves is about 20 per cent. It has a brownish-green color and a characteristic rather heavy odor. On account of the large proportion of resinous matter in the leaves, it is essential that the percolate be constantly stirred during evaporation, especially toward the end of the operation, otherwise a granular product may result from separation of the resin as the alcoholic strength changes. The extract is used almost exclusively for the preparation of stramonium ointment.

Action and Uses.—For the action and uses of Extractum Stramonii, see STRAMONIUM. The dose is from $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.).

EXTRACTUM STROPHANTHI, *Br.*—Extract of Strophanthus.

Extrait de semences de strophantus, Fr.; *Strophantusextrakt*, G.

Preparation.—Strophanthus seeds, reduced to No. 30 powder and dried at 43.3° C. (110° F.), 1 ounce; purified ether, alcohol (90 per cent.), milk sugar, of each a sufficient quantity. Pack the dried powder in a percolator, and, having moistened it with the ether, macerate for 24 hours; then allow percolation to proceed, continuing the addition of ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 48.9° C. (120° F.). Again reduce it to powder, repack in the percolator, and moisten with the alcohol. Macerate for 48 hours, then pour on successive quantities of the alcohol, percolating slowly, until 10 fluidounces of liquid are obtained. Evaporate most of the alcohol; transfer the residual liquid to a counterpoised basin; concentrate until the liquid begins to thicken; then add sufficient finely powdered milk sugar to produce 2 ounces of extract, in powder.—Br.

The treatment of the powdered seeds with ether is for the purpose of removing the fixed oil, the presence of which would interfere with final powdering of the extract. Purified ether, freed as far as possible from alcohol and water, is directed so as to avoid solution of the active principle strophanthin. The finished extract represents one-half its weight of strophanthus seed, and is a very convenient form of administration of the drug.

Action and Uses.—This extract is employed for the same purposes as STROPHANTHUS (which see). The dose is from $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.).

EXTRACTUM SUMBUL, *U. S.*—Extract of Sumbul.

Extract of muskroot, E.; *Extrait de racine de sumbul*, Fr.; *Sumbulwurzelextrakt, Moschuswurzelextrakt*, G.

Preparation.—Fluidextract of sumbul, 100 Cc. Evaporate the fluidextract of sumbul in a porcelain capsule by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.—U. S.

The yield of extract of sumbul is about 15 per cent. It is impossible to obtain a perfect pilular condition in the case of this extract, owing to the peculiar nature of the resin and oil present in the drug. It is of a yellowish-brown color and has the characteristic strong odor of the root, reminding of musk.

Action and Uses.—Extract of sumbul is employed principally in the treatment of nervous exhaustion. The dose is from 1 to 5 grains (0.05–0.30 Gm.).

EXTRACTUM TARAXACI, *U. S., Br., P. G.*—Extract of Taraxacum.

Extract of dandelion, E.; *Extrait de pissenlit* (*de dent de lion*), Fr.; *Löwenzahnextrakt*, G.; *Estratto di tarassaco*, It.

Preparation.—Taraxacum, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity. . Mix 125 Cc. of alcohol with 875 Cc. of water, and, having moistened the powder with 250 Cc. of the mixture, pack it in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the taraxacum is exhausted. Evaporate the percolate, by means of a water-bath, to a pilular consistence.—U. S.

The Br. P. directs fresh taraxacum root to be crushed and expressed; after subsidence of the starchy matter the juice is heated to 100° C. (212° F.) for 10 minutes, strained, and evaporated to the consistence of a soft extract. Collected in the autumn, the fresh root yields 8 to 10 per cent. of extract; the fresh spring root yields a smaller amount. The P. G. directs the dried root to be exhausted with cold water by maceration and subsequent expression, the united infusions being evaporated to twice the weight of the drug, mixed with alcohol, allowed to deposit, filtered, and evaporated to a pilular consistence.

The present official directions differ materially from those of the last pharmacopœia, which consisted in expression and evaporation of the juice of the root freshly gathered, without provision for removal of the starchy and albuminous constituents. Very little extract was probably made from the fresh root. The above treatment with a weak alcoholic menstruum guards against fermentative changes during the period of maceration and percolation, and yields a satisfactory product.

Extract of taraxacum is of a brown color and yields a nearly clear solution with water. It has a decidedly bitter taste.

Action and Uses.—See TARAXACUM. This preparation does not keep well; for this reason a freshly prepared article should be employed. The dose is from 10 to 20 grains (0.60–1.3 Gm.).

F.

FABIANA.—Pichi.

The dried leafy twigs of *Fabiana imbricata* R. et P. (Fam. *Solanaceæ*).

Origin.—From a large terebinthinate shrub of northern Chile, somewhat resembling a Juniper and somewhat a Tamarisk shrub. Botanically, it is closely related to tobacco.

FIG. 179.

Fabiana (slightly reduced).

Description.—Branches, the largest not exceeding 6 Mm. ($\frac{1}{4}$ In.) in diameter, light brown-gray, smoothish or somewhat warty, enclosing a yellowish tough wood, to which the bark tightly adheres; branchlets very numerous, short, mostly erect, terminating in solitary flowers, very leafy; leaves scale-like, closely imbricated, about 1 Mm. ($\frac{1}{25}$ In.) long, sessile, ovate, entire, smooth, bluish-green; flowers about 1.25 Cm. ($\frac{1}{2}$ In.) long, the calyx very small, the white or purplish corolla tubular, 5-toothed; fruit a small 2-celled and 2-valved capsule, containing a few angularly subglobular seeds; odor peculiarly aromatic; taste bitter, terebinthinate, and disagreeable.

The large branches, and even the trunks, are frequently included, but should be rejected, since the wood is nearly inert, notwithstanding that it is often employed by the natives.

Constituents.—Besides 2 per cent. of gum, fat, a caoutchouc-like body, and a small quantity of volatile oil containing *fabianol*, pichi yields 0.1 per cent. of a bitter ether-soluble alkaloid, *fabianine*, with crystalline salts (Lyons), a tasteless, neutral, inert resin ($C_{18}H_{31}O_2$) in white acicular crystals, much bitter resin soluble in alcohol, ether, chloroform, and alkalies, and a bitter fluorescent glucoside resembling æsculin. This fluoresces blue with ammonia water, and pink with acids, and forms light nearly white crystals. Some investigators have failed to find the alkaloid.

Action and Uses.—Pichi has been employed as a diuretic, lithontriptic, tonic, and cholagogue. This remedy has been recommended especially in the treatment of subacute and chronic vesical catarrh and in renal disease resulting from the presence of calculi. Some practitioners assert that it is of great value in hæmaturia and renal congestion. The drug is said to be useful also in the later stages of gonorrhœa and in gonorrhœal prostatitis. Pichi may be employed in the treatment of hepatic torpor accompanied by indigestion. The dose of the fluid extract is from $\frac{1}{2}$ to 1 drachm (2–4 Cc.), 3 times daily, and of the extract from 5 to 10 grains (0.30–0.60 Gm.).

FARINA AVENÆ.—Oatmeal.

Farina d'avoine, Fr.; *Hafermehl*, G.

The meal prepared from the grain of *Avena sativa* L. (Fam. *Gramineæ*).

Oatmeal was official in the U. S. P. of 1870.

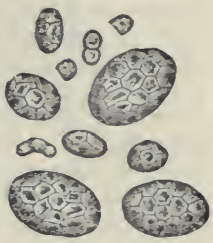
The common oat of cultivation, its nativity doubtful, is too well known to require discussion. *Groats* are oats deprived of their husk.

Description.—Oatmeal is a grayish-white not uniform powder, in which fragments of the tissue are observed by the naked eye; it has a slight odor and a somewhat bitterish taste. Viewed under the microscope, the starch consists of medium-sized polyhedral or muller-shaped granules, with a rather distinct hilum, but without observable laminæ. Frequently two or

three are united, or even a larger number, forming a nearly spherical mass with a checkered surface, and readily separating by pressure into the separate granules.

Constituents.—Oats consist on an average of 25 per cent. of husks and 75 per cent. of grain; the former contains 1 to 1.5 per cent. of fixed oil, 0.5 to 0.75 per cent. of sugar and gum, nearly 2 per cent. of protein compounds, and 6.5 to 7 per cent. of ash, the remainder being cellulose. The grain contains 64.5 to 66 per cent. of starch, 5 to 7 per cent. of fat, 18 to 21 per cent. of protein compounds, 1 to 3 per cent. of salts, the remainder being sugar, gum, and cellulose. The largest portion of the protein compounds is *avenin*, which may be obtained from oatmeal by treating it in the cold with a weak solution of potassium hydroxide, decanting from the sediment, and precipitating by acetic acid; the impure avenin is washed with diluted and strong alcohol and ether, redissolved in weak potassium hydroxide solution, and precipitated by acetic acid (Kreusler, 1869). Avenin closely resembles legumin in its behavior to solvents; it contains 17 per cent. of nitrogen and 0.75 to 1 per cent. of oxygen.

FIG. 180.



Oat starch (× 250).

Action and Uses.—Gruel prepared from oatmeal affords a nutritious, easily digested food which is admirably adapted to certain inflammatory conditions of the alimentary tract. Because of its laxative properties it may be of advantage in the treatment of chronic constipation, and may also be given with purgatives to modify their action. An emollient poultice is sometimes prepared by boiling oatmeal with water to a thick paste, and a thin paste prepared in the same manner has been used as an enema. Oatmeal gruel may be made by boiling 2 ounces (60 Gm.) of the meal with 3 pints (1440 Cc.) of water until only 2 pints (960 Cc.) remain, after which it is cooled and strained. The supernatant liquid is then decanted, and the remaining portion may be flavored with sugar, lemon, vanilla, etc., to suit the taste.

FARINA TRITICI, *Br.*—Wheaten Flour.

Wheat flour, E.; *Farine de blé (de froment)*, Fr.; *Weizenmehl*, G.; *Harina de trigo*, Sp.

The grain of wheat, *Triticum sativum* Lam. (*T. vulgare* Villars.—Fam. *Gramineæ*), ground and sifted.

The origin and general appearance of this substance are too well known to require discussion. Several other species, with their hybrids, contribute a portion of the wheat of cultivation. The identity of wheat flour can be determined from the appearance of its starch-grains (see AMYLUM).

Wheat grain, like the similar graminaceous fruits, has the integuments of the fruit and seed united; underneath this covering is a layer of cells containing *gluten*, and then follows the cellular tissue of the so-called albumen or endosperm, this being filled with *starch;* the embryo is located at the base of the endosperm. Wheat is most generally prepared for food by grinding, and separating by means of sieves the broken integuments, or *bran*, from the fine amylaceous white portion, or *flour*.

Composition.—The relative amounts of the different constituents differ considerably in winter and spring wheats; also according to the variety and hardness, and the producing locality. The following average composition of entire wheat given by König is accepted: water, 13.56 per cent.; nitrogenous substances, 12.42; fat, 1.7; sugar, 1.44; gum and dextrin, 2.38; starch, 64.07; fiber, 2.66; ash, 1.79. The bran, separated, contains, approximately: water, 12 per cent.; insoluble nitrogen, 13.5; soluble nitrogen, 3; fat, 4; carbohydrates, 64; fiber, 9; ash, 7.

If wheat flour be kneaded with cold water as long as the liquid becomes milky, a yellowish-gray elastic and glutinous mass remains, which is the *gluten* of Beccaria, retains about 70 per cent. of water, and consists, according to von Bibra, in the dry state, of about 70 per cent. of *vegetable fibrin*, 3.8 to 9.3 of *vegetable casein*, 7.5 to 19.5 of *glutin*, and 4.6 to 8.2 of fat. On drying, it assumes a horn-like appearance and partly loses its solubility in phosphoric acid and potassium hydroxide solution. To purify it, Ritthausen (1862–67) dissolves it in cold very dilute potassium hydroxide solution (1 to 1000 parts of water), decants from the undissolved starch, and pre-

cipitates with acetic acid. The precipitate is repeatedly treated with fresh portions of alcohol, commencing with specific gravity 0.914, and increasing the strength finally to absolute alcohol. After another washing with ether the insoluble portion constitutes *gluten-casein*, which is slightly soluble in acetic acid, freely soluble in potassium hydroxide solution, and becomes insoluble by heat. On evaporating the united alcoholic liquids to one-half and cooling, *gluten-fibrin* is separated, which is purified by dissolving it repeatedly in 50 and 60 per cent. alcohol. It is freely soluble in dilute acetic acid, and when boiled with water, in which it is insoluble, it is converted into a jelly. After the separation of gluten-fibrin the greater portion of the alcohol is evaporated; the precipitate appearing on cooling is treated with a little alcohol, washed with ether, dissolved in a little 65 per cent. alcohol, and precipitated by absolute alcohol. The precipitate is *mucedin;* the solution contains *gliadin.* Both principles are freely soluble in diluted alcohol and in weak acids and alkalies. The above are the most important *vegetable protein compounds*, and contain between 0.5 and 1 per cent. of sulphur, and between 15 and 18 per cent. of nitrogen.

Action and Uses.—Wheat flour is rarely employed in the treatment of disease, but as a dusting-powder has been used to relieve the burning pain of erysipelas, superficial burns, and other inflammations of the skin attended with burning and itching. In the form of toasted bread or an uncooked paste it may be used for the relief of summer diarrhœa or that depending upon debility. As an emollient poultice it may be wet with milk and directly applied. Bread-crumbs are also employed to give bulk and consistence when minute doses of drugs are prescribed in pill-form.

Horse bran is an article of food, and may be tried as a domestic remedy for constipation. The ash obtained from the burned stalks and husks has been mixed with white wine and given as a diuretic.

FEL BOVIS, *U. S.*—Ox-gall.

Fel bovinum, Fel tauri, Bilis bubula.—Ox-bile, E.; *Bile (Fiel) de bœuf,* Fr. Cod.; *Ochsengalle, Rindsgalle,* G.; *Hiel de toro, Bilis de buey,* Sp.; *Fel de Boi,* Port.

The fresh bile of *Bos Taurus* L. (Ord. *Ruminantia*).

Ox-gall is official in but few pharmacopœias.

Properties.—A green, or brownish-green, viscid, transparent or more frequently translucent liquid, of a peculiar odor, more prominent on heating, a nauseous sweet and bitter taste, a specific gravity of 1.015 to 1.025 at 25° C. (77° F.), a slight alkaline or sometimes a neutral reaction, dissolving completely when agitated with water; becoming thinner on warming, and then readily strained through moistened muslin, whereby fragments of tissue, epithelium, etc., are removed; mixed with its own weight or twice its bulk of alcohol, a precipitate is produced consisting almost exclusively of mucilaginous matter, and the liquid filtered from it and freed from alcohol by evaporation resists putrefaction for a long time. A mixture of 2 drops of ox-gall and 10 Cc. of water, when treated, first, with a drop of freshly prepared solution of 1 part of sugar in 4 parts of water, and afterward with sulphuric acid, cautiously added until the precipitate first formed is redissolved, gradually acquires a brownish-red color, changing successively to carmine, purple, and violet.—U. S.

Constituents.—The most important constituents are about 3 per cent. each of the glycocholates and taurocholates of sodium and potassium, and the bile-pigments bilirubin and biliverdin. Besides these, bile contains fat (the glycerides of acetic and propionic acids), soaps, mucin, albuminous matter, choline, cholesterin ($C_{26}H_{43}OH$), traces of urea, the potassium, sodium, magnesium, and calcium phosphates, the potassium and sodium chlorides, and iron, manganese, and silica. *Bilirubin* ($C_{32}H_{36}N_4O_6$) is an orange or red substance insoluble in water, soluble in chloroform and alkalies, and slightly soluble in alcohol and ether. *Biliverdin* ($C_{32}H_{36}N_4O_9$), of dark-green color, is soluble in alcohol and alkalies, but not in water, chloroform, or ether. The relative proportion of these pigments gives the bile a yellow, brown, or green color, ox-gall being brown from a preponderance of bilirubin. This latter pigment is quickly changed to biliverdin by oxidation, as when exposed to air in alkaline solution. Other bile-pigments described are dark-brown *bilifuscin*, greenish-black *biliprasin*, blackish *bilihumin*, and bluish *bilicyanin*. Glycocholic acid ($C_{26}H_{43}NO_6$) may be split up into cholic acid ($C_{24}H_{40}O_5$) and glycine or glycocoll or amidoacetic acid ($C_2H_5NO_2$); taurocholic acid

($C_{26}H_{45}NSO_7$) splits into cholic acid and taurine ($C_2H_7NSO_3$). Pigs' bile yields also hyoglycocholic ($C_{27}H_{43}NO_5$) and hyotaurocholic ($C_{27}H_{45}NSO_6$) acids.

Action and Uses.—Ox-gall has been largely employed in the treatment of atonic dyspepsia, constipation, and many other complaints depending upon hepatic torpor or functional obstruction of the biliary passages. Some obstetricians think it especially valuable if given in water as an enema to unload the large bowel. It has been given as a vermifuge, tonic, and laxative, in doses of from 5 to 10 grains (0.30–0.60 Gm.). While all experimenters are agreed that it increases the flow of bile, clinicians are by no means convinced of this.

FEL BOVIS PURIFICATUM, *U. S.*—Purified Ox-gall.

Fel bovinum purificatum, Br.; *Purified ox-bile*, E.; *Fiel de bœuf purifié*, Fr.; *Gereinigte Ochsengalle*, G.

Preparation.—Fresh ox-gall, 300 Cc.; alcohol, 100 Cc. Evaporate the ox-gall in a tared porcelain capsule, on a water-bath, to about 100 Gm., then add to it the alcohol, mix the whole thoroughly, and set it aside, well covered, for 3 or 4 days. Then decant the clear solution, filter the remainder, and, having mixed the liquids, and distilled off the alcohol, evaporate the remainder to a pilular consistence.—U. S.

The Br. P. directs that 1 pint of fresh ox-bile shall be evaporated to $\frac{1}{4}$ its volume and then mixed with $\frac{1}{2}$ pint of 90 per cent. alcohol and set aside until the solid matter has subsided, after which the process is continued as stated above, except that the final liquid mixture is evaporated to the consistence of a thick extract, instead of a pilular consistence.

The object of the purification is the removal of mucilaginous and inorganic matter, which former would render the ox-gall tough upon evaporation.

Properties.—It is a yellowish-green hygroscopic solid, having a partly sweet and partly bitter taste and a peculiar odor, and is very soluble in water and alcohol. A solution of purified ox-gall in water (1 per cent., U. S.; 3 or 5 per cent., Br.), when treated with fresh solution of sugar and then with sulphuric acid, as directed in the preceding article, will develop the same play of colors as there mentioned. The quality of purified ox-gall may be readily tested by addition of water, when a clear solution should result, which remains clear upon admixture with an equal volume of alcohol.

Action and Uses.—The employment of purified ox-gall is discussed under FEL BOVIS (which see).

FERRI ARSENAS, *Br.*—Iron Arsenate.

Ferrum arsenicum. — *Ferrous arsenate*, E.; *Arséniate ferreux*, Fr.; *Arsensaures Eisenoxydul*, G.

Ferrous arsenate, $Fe_3(AsO_4)_2.6H_2O_9$, with ferric arsenate and some iron oxide.—Br.

Preparation.—Dissolve 530 Gm. of anhydrous sodium arsenate in 2 liters, and 415 Gm. of crystallized ferrous sulphate in $2\frac{1}{2}$ liters, of distilled water; mix the solutions and add 90 Gm. of sodium bicarbonate dissolved in a little cold distilled water, stirring thoroughly. Collect the precipitate on a calico filter, and wash until barium chloride shows the absence of sulphate in the filtrate, squeeze the water from the precipitate, and dry on porous tiles in an air-bath not above 37.8° C. (100° F.).—Br.

The reaction taking place primarily is as follows: $3(FeSO_4.7H_2O) + 2Na_2HAsO_4 + 2NaHCO_3 = Fe_3(AsO_4)_2.6H_2O + 3Na_2SO_4 + 17H_2O + 2CO_2$. By this reaction, theoretically 1 part of crystallized ferrous sulphate requires 0.45 part of anhydrous sodium arsenate, while the proportion in the Br. P. is 1 part of ferrous sulphate to 1.27 part of arsenate, which seems to be an excess of about 182 per cent. of arsenate. The excessive quantity of arsenate and method of preparation have been criticised by Thomas S. Barrie (*Chemist and Druggist*, 1900) and F. B. Power (*Pharm. Jour.*, 1900).

The directions in the Fr. Cod. are still more inconsistent, and it is improbable that the compound obtained has the formula given, namely, $FeHAsO_4$. No other pharmacopœias recognize ferrous arsenate.

The object of the sodium bicarbonate in the Br. process is to neutralize the free sulphuric acid which would be formed in the reaction. The Fr. Cod. omits the bicarbonate. The white precipitate of ferrous arsenate is very bulky, and while being washed to free

it from the mother-liquor and dried, it is oxidized and converted into ferroso-ferric arsenate. The change is indicated by the gradual disappearance of the white color until the salt finally becomes olive-green or blue-green. In the reaction and final result the process corresponds nearly with the one for the blue iron phosphate.

Properties.—Iron arsenate is a green or blue-green amorphous powder insoluble in water and in alcohol, but dissolving readily in dilute hydrochloric acid, yielding a bright-yellow solution in which blue precipitates are produced with both ferrocyanide and ferricyanide of potassium, and which yields with hydrogen sulphide first a milkiness (sulphur), and afterward a yellow precipitate of arsenic sulphide. It may be distinguished from iron phosphate, which resembles it in appearance, by boiling a small portion with an excess of caustic soda, filtering, and neutralizing exactly with nitric acid, when a brick-red precipitate of silver arsenate will be produced on the addition of silver nitrate. Iron phosphate similarly treated yields a yellow precipitate. The Br. P., oddly enough, gives directions for determining the amount of ferrous arsenate, instead of the more potent arsenic acid. 1 Gm. dissolved in an excess of sulphuric acid and diluted, should require at least 6.7 Cc. of decinormal potassium dichromate solution before it ceases to give a blue color with solution of potassium ferricyanide, corresponding to about 12.5 per cent. of hydrous, or 10 per cent. of anhydrous ferrous arsenate. No sulphate should be present.

Action and Uses.—Iron arsenate is of little value in medicine. It is said to combine the properties of both iron and arsenic, but the quantity of the former is probably too small to be of material value. The remedy may be employed for the same conditions in which arsenic is used. The beginning dose is $\frac{1}{20}$ grain (0.003 Gm.), which may be gradually increased to ½ grain 0.03 Gm.).

FERRI CARBONAS SACCHARATUS, *U. S.*, *Br.*—Saccharated Ferrous Carbonate.

Ferrum carbonicum saccharatum, P. G.—*Saccharated carbonate of iron*, E.; *Saccharure de proto-carbonate de fer* (*de carbonate ferreux*), Fr.; *Zuckerhaltiges Ferrocarbonat*, G.

Formula of pure ferrous carbonate, $FeCO_3$ (anhydrous). Molecular weight, 115.05.

The Br. P. product is described as a more or less oxidized ferrous oxycarbonate, $(FeCO_3)Fe(OH)_2$, the ferrous salt, calculated as ferrous carbonate, forming about one-third of the saccharated mixture.

The saccharated mixture contains 16.1 per cent. (Br.), about 7.25 per cent. (U. S.), of metallic iron in the ferrous state; 9.5–10 per cent. (P. G.) of total iron.

About 33 per cent. (Br.), about 15 per cent. (U. S.), of ferrous carbonate.

Preparation.—Dissolve 50 parts of ferrous sulphate in 200 parts of boiling distilled water and filter; dissolve 35 parts of sodium bicarbonate in 500 parts of distilled water at 50° C. (122° F.) and filter; add the former solution gradually to the latter and mix thoroughly by rotating the flask. Fill the flask with boiling distilled water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a syphon, and then fill the flask again with hot distilled water in the same manner, until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally bring the precipitate on a muslin strainer, and, when it has thoroughly drained, transfer it to a porcelain capsule containing 80 parts of sugar in fine powder, and mix intimately. Evaporate the mixture to dryness by means of a water-bath, reduce it to powder, and mix intimately with it, if necessary, sufficient well-dried sugar to make the final product weigh 100 parts. Keep the product in small, well-stoppered bottles. The proportions used above are identical with those of the U. S. P., in which weight in Gm. is directed.

Both the British and German Pharmacopœias mix the iron and alkali solutions while hot, and thereby avoid absorption of oxygen during cooling; in other respects the manipulations do not materially differ. For 10 parts of ferrous sulphate there are ordered 7 parts of sodium bicarbonate (P. G.), 6¼ parts of ammonium carbonate (Br.); and the ferrous carbonate thus obtained is mixed with sugar 5 parts (Br.) (yield 9¾ parts); first with milk-sugar 2 parts and cane-sugar 6 parts, and when dry with sufficient cane-sugar to make 20 parts (P. G.).

Ferrous sulphate and sodium bicarbonate decompose each other, forming ferrous carbonate, carbon dioxide, and sodium sulphate; thus, $FeSO_4 + 2NaHCO_3 = FeCO_3 + CO_2 + H_2O + Na_2SO_4$. The operation must be performed with the air excluded as much as possible; hence the importance of employing boiling water from which the air has been expelled, of generating carbon dioxide during the operation by the use of sodium bicarbonate, of performing the washing by decantation in deep cylindrical and well-covered vessels, and of collecting and draining, or, as directed by the Br. P., expressing the precipitate rapidly; the subsequent addition of sugar will, in a measure, protect it against oxidation until it has been finally dried.

Properties.—Ferrous carbonate forms small lumps or a gray or greenish-gray inodorous powder, having a neutral reaction to moistened litmus-paper, and a sweet taste like that of sugar, followed by a very feeble chalybeate taste. On exposure to dry air it is slowly, or in damp air rapidly, oxidized, and is therefore best preserved in small well-filled and sealed vials; if it has changed to a brown color and effervesces only slightly with acids, it should be rejected. When heated in contact with the air, it becomes black, evolving the odor of burning sugar, and is finally converted into red-brown ferric oxide. Water dissolves only the sugar, but the powder is completely dissolved with effervescence in dilute hydrochloric acid, and this solution gives a blue precipitate with both potassium ferricyanide and ferrocyanide, showing the presence of ferrous and of ferric salt.

Tests.—The powder, placed upon moistened red litmus-paper, should not change the red color to blue (absence of alkali). The solution in diluted hydrochloric acid should yield no precipitate or but a slight turbidity with barium chloride, indicating only traces of sulphate left behind from the mother-liquor.

If 1.15 Gm. of saccharated ferrous carbonate be dissolved in 10 Cc. of diluted sulphuric acid, and the solution diluted with water to about 100 Cc., it should require not less than 15 Cc. of tenth-normal potassium permanganate solution before the pink tint imparted to the liquid ceases immediately to disappear, corresponding to not less than 15 per cent. of ferrous carbonate (each Cc. of the volumetric solution indicating 1 per cent. of pure ferrous carbonate).—U. S. The Br. P. demands about one-third of anhydrous ferrous carbonate, and that 1 Gm. should be oxidized by at least 29 Cc. of the volumetric solution of potassium dichromate, indicating not less than 16.1 per cent. of ferrous iron or 33.3 per cent. of ferrous carbonate. If none of the ferrous salt had been oxidized, the powder would contain 20.85 per cent. (U. S., P. G.), 42.8 per cent. (Br.), of anhydrous ferrous carbonate. The German Pharmacopœia determines the total iron only.

Action and Uses.—This remedy is employed in the treatment of chlorosis, neuralgia, and other affections depending upon anæmia. It has been introduced as a substitute for the subcarbonate of iron, and is superior to the latter because of the fact that the iron is nearly all in the ferrous state. The dose is from 5 to 20 grains (0.30–1.3 Gm.), several times daily.

FERRI CHLORIDUM, *U. S.*—Ferric Chloride.

Ferrum sesquichloratum, P. G.; *Ferrum muriaticum oxydatum, Ferri perchloridum.—Sesquichloride (Perchloride) of iron*, E.; *Perchlorure de fer, Chlorure ferrique*, Fr.; *Eisenchlorid*, G.

Formula, $FeCl_3.6H_2O$ or $Fe_2Cl_6.12H_2O$. Molecular weight, 268.32 or 536.64.

It should contain not less than 20 per cent. of metallic iron in the form of chloride.—U. S.

Preparation.—Evaporate 100 Gm. of solution of ferric chloride on a water-bath until it weighs 50 Gm. Set it aside in a glass-covered vessel until it forms a crystalline mass. Break the salt into pieces and keep it in glass-stoppered bottles, protected from light.—U. S.

Instead of grams, avoirdupois ounces may be used in the directions above. During evaporation and the subsequent operation the use of iron spatulas or stirrers should be carefully avoided; only porcelain or glass should be used. On evaporating a solution of ferric chloride to the crystallizing-point, vapors containing hydrochloric acid are given off as soon as the temperature reaches a certain point, which varies with the strength of the solution; and if the heat is raised to the boiling-point, ferric chloride is

mechanically carried off. Evaporation should be done at a gentle heat, and it will be found of advantage to have a slight excess of hydrochloric acid at the beginning of the evaporation. The crystallization may be effected by keeping the capsule in a warm place until the contents solidify, but the crystals will then be very damp. When evaporation has been carried too far, a salt, $FeCl_3 + 3H_2O$, is formed which is very deliquescent.

Another procedure is to evaporate the solution to less than half its weight; on cooling the mass will now remain liquid, and is set aside loosely covered to protect it from dust and other impurities, and at the same time to admit the atmosphere, from which it will attract moisture and gradually crystallize. The crystals begin to form as small circular nodules having a radiated appearance, floating upon the liquid, and increasing in size until the entire liquid forms a solid mass, which adheres firmly to the vessel. By warming it slightly the mass is readily detached, and should at once be broken into pieces and put into dry, well-stoppered bottles.

Properties.—The official ferric chloride forms orange-colored wart-like pieces which have a crystalline texture and a slight odor of hydrochloric acid, are very deliquescent, forming a thick red-brown liquid having a density of about 1.55, and formerly known as *Oleum martis per deliquium.* The salt is readily and completely soluble in water and alcohol, also in a mixture of 1 part of ether and 3 parts of alcohol, yielding yellowish-brown solutions of an acid reaction and a strongly styptic, ferruginous taste. The crystals fuse at 35.5° C. (96° F.); at a higher temperature they are decomposed and partly volatilized. The aqueous solution shows the reactions of ferric salts and chlorides in yielding a red-brown precipitate with ammonia water and other alkalies, a blue one with potassium ferrocyanide, and a white one, insoluble in nitric acid, with silver nitrate.

Tests.—The complete solubility in the solvents mentioned is generally an indication of the absence of other metallic salts. The presence of nitric acid or of ferrous salt is detected as described above. 1 Gm. of the salt in boiling water, when precipitated by an excess of ammonia-water, should give a colorless filtrate, 20 Cc. of which, after acidulating with hydrochloric acid, should give no color or turbidity with an equal volume of hydrogen sulphide solution when standing corked at 35° C. (95° F.) for at least half an hour, either before or after making alkaline with ammonia-water (absence of other heavy metals). If to 3 drops of an aqueous solution of the salt (1 in 2) 10 Cc. of tenth-normal sodium thiosulphate solution be added and then slowly heated to boiling, no brown precipitate of ferric hydroxide should separate (absence of oxychloride). The ferric chloride is reduced to ferrous with formation of sodium tetrathionate, $2FeCl_3 + 2Na_2S_2O_3 = 2FeCl_2 + 2NaCl + Na_2S_4O_6$. Any ferric hydroxide which was held in solution by ferric chloride is precipitated after reduction of the latter takes place. If 1 Gm. of anhydrous ferric chloride be dissolved in water to 100 Cc., then 55.5 Cc. of this solution placed in a glass-stoppered flask (250 Cc.) with 3 Cc. of hydrochloric acid and 2 Gm. of potassium iodide, should, after securely fastening the stopper and heating for half an hour at 40° C. (104° F.) and cooling, require not less than 20 Cc. of tenth-normal sodium thiosulphate solution for complete decolorization (each Cc. of the volumetric solution indicating 1 per cent. of metallic iron).—U. S.

The volumetric determination of iron by means of potassium iodide and sodium thiosulphate depends upon the well-known reaction of the former salt and ferric chloride, whereby iodine is liberated; thus, $2FeCl_3 + 2KI = I_2 + 2FeCl_2 + 2KCl$, the ferric salt being at the same time reduced to the ferrous state; 322.08 parts of anhydrous or 536.64 parts of official ferric chloride correspond to 251.80 parts of iodine, and hence each Cc. of sodium thiosulphate solution necessary to discharge the brown color of iodine will represent 0.02683 Gm. of $FeCl_3 + 6H_2O$, corresponding to 0.005550 Gm. of metallic iron. The iodine liberated is held in solution by an excess of potassium iodide.

Action and Uses.—Ferric chloride is rarely employed in internal medicine except in the form of the tincture or solution. The internal uses of the remedy will be discussed under TINCTURA FERRI CHLORIDI (which see). The drug is astringent and styptic, and solutions varying in strength from 15 to 90 per cent. have been employed in the treatment of epistaxis, hæmoptysis, and the bleeding following tooth-extraction and other minor operations. It has been suggested as an injection for the cure of varices and aneurism, but its employment in these conditions is not considered a safe procedure. The deliquesced salt has also been applied as a caustic and styptic to lupoid and scrofulous ulcers.

FERRI CITRAS, *U. S.*—Ferric Citrate.

Ferrum citricum oxydatum, P. G.—*Citrate of iron*, E.; *Citrate de sesquioxide de fer, Citrate ferrique*, Fr.; *Eisencitrat, Citronensaures Eisenoxyd, Ferricitrat*, G.

Formula, $Fe(C_6H_5O_7)$ (anhydrous). Molecular weight, 243.12.

Preparation.—Freshly prepared ferric hydroxide, obtained from 1050 Gm. of solution of ferric sulphate, is added to 300 Gm. of citric acid, and the mixture heated on a water-bath to 60° C. (140° F.) until solution is effected. After filtration the clear liquid is evaporated, at the same temperature, to the consistence of syrup and spread on plates of glass, so that, when dry, the salt may be obtained in scales.

At a higher temperature than indicated by the formula the salt is slowly reduced to a ferrous compound. When the solution is concentrated to a thick, syrupy liquid, it is spread on plates, and then dried in a dry or warm place. Failure in scaling is usually due to incomplete saturation of the citric acid with ferric hydroxide, occasionally to the presence of saline impurities retained by the carelessly washed hydroxide. The yield is from 42 to 44 per cent.

The amount of water of hydration varies considerably, and hence no definite formula can be assigned to the official scale salt; much confusion exists in the literature upon the subject, some authors assigning as low as 3.5 per cent., while others claim 18–20 per cent. of water. F. B. Power (1891) found the amount of water present in scales of ferric citrate, carefully prepared by himself, to average 31.9 per cent.; the same author also determined that all water of hydration is eliminated at 100° C. (212° F.). The variable proportion of water may be due to difference in temperature employed, subsequent exposure, etc. The U. S. P. requires the presence of at least 16 per cent. of metallic iron, which is somewhat less than the German Pharmacopœia, which requires 19 to 20 per cent. of iron. It should be kept in well-stoppered bottles, protected from light.

Properties.—If of the proper composition, the salt readily comes off the plates in the form of thin, transparent, garnet-red scales which yield a red-brown powder, are permanent in the air, inodorous, and have a faint ferruginous taste and an acid reaction. It is insoluble in alcohol, and dissolves completely but slowly in cold water, and easily in boiling water, but diminishes in solubility by age. Its solution is darkened, but not precipitated, by ammonia. When strongly heated, the salt is decomposed, emitting fumes having the odor of burnt sugar, and leaving an ash consisting of ferric oxide. On being boiled with an excess of potassium hydroxide solution, the salt or its solution yields a precipitate of ferric hydroxide, and the filtrate, on being neutralized with acetic acid and then boiled with test-solution of calcium chloride, gives a white granular precipitate of calcium citrate. With potassium ferrocyanide test-solution it affords a bluish-green color or precipitate, which is increased and rendered dark-blue by the subsequent addition of hydrochloric acid (difference from ammonio-citrate of iron). If heated with potassium hydroxide test-solution it affords a brownish-red precipitate, without evolving vapor of ammonia.

Tests.—Ferric citrate is not liable to adulteration. The presence of tartaric acid would be detected by precipitating a boiling solution of the salt (1 in 10) with excess of potassium hydroxide, acidulating the filtrate with acetic acid, cooling, and allowing to stand 24 hours, when no white crystalline precipitate should appear (absence of tartrate). The ash obtained by incinerating the salt should not have an alkaline reaction (absence of fixed alkalies). If 0.555 Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, with the aid of a gentle heat, and, after the addition of 1 Gm. of potassium iodide, the mixture kept for half an hour at a temperature of 40° C. (104° F.), and then allowed to cool, it should require not less than 16 Cc. of tenth-normal sodium thiosulphate solution before the color of the liquid is discharged (each Cc. of the volumetric solution indicating 1 per cent. of metallic iron).—U. S.

The object of heating the ferric citrate with hydrochloric acid is to convert the citrate into chloride, after which the determination proceeds as explained under the latter.

Action and Uses.—Ferric citrate is one of the less astringent preparations of iron. It is best administered in solution, and is less liable to derange digestion than the astringent salts. The dose of the salt is from 3 to 10 grains (0.2–0.60 Gm.).

FERRI ET AMMONII CITRAS, *U. S., Br.*—Iron and Ammonium Citrate.

Ferrum citricum ammoniatum, Ferri ammonio-citras, Ferro-ammonium citricum.—Ammonio-ferric citrate, Ammonio-citrate of iron, Soluble citrate of iron, E.; *Citrate de fer et d'ammoniaque (de fer ammoniacal), Citrate ferrique ammoniacal,* Fr.; *Ferriammoniumcitrat, Citronensaures Eisenoxyd-Ammonium (Ammoniak),* G.

Preparation.—Iron and ammonium citrate may be prepared by adding to a solution of ferric citrate ammonia-water in slight excess, evaporating the mixture, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spreading it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place. It is deliquescent in moist air.

The process of manufacture has been dropped from the U. S. P.

In the Br. P. ferric citrate is prepared by first dissolving the ferric hydroxide obtained from 10 fluidounces of solution of ferric sulphate, in 4 ounces of citric acid dissolved in an equal weight of water and heated on a water-bath. After cooling, $5\frac{1}{2}$ fluidounces of solution of ammonia are added, the liquid is filtered and evaporated to a syrup, which is dried on glass plates at a temperature not above 37.8° C. (100° F.).

Properties and Tests.—The salt, which is sometimes sold as soluble citrate of iron, closely resembles ferric citrate in appearance and behavior, except that it has a neutral reaction, is more readily soluble in cold water, gives off the odor of ammonia when heated with an excess of potassium hydroxide solution, and does not strike a blue color on mixing its solution with potassium ferrocyanide unless it be acidulated with hydrochloric acid. Impurities, if present, may be determined in the same manner. On ignition, the salt yields about 31–32 per cent. (Br.) of ferric oxide. Being made from normal ferric citrate with the addition of ammonia, it is probably a mixture or compound of ammonio-ferric citrate with ferric oxycitrate. As in the case of ferric citrate, so also here, the Pharmacopœia requires the presence of at least 16 per cent. of metallic iron, which is determined in exactly the same manner as in the case of ferric citrate.

Action and Uses.—This salt has no advantage over ferric citrate except that it is more soluble. It should always be given in solution, and may be combined with carbonated alkalies and given in a state of effervescence by the addition of a solution of citric acid. The dose is from 2 to 5 grains (0.12–0.30 Gm.), several times daily.

FERRI ET AMMONII SULPHAS, *U. S.*—Ferric Ammonium Sulphate.

Ferrum sulfuricum oxydatum ammoniatum, Ferrum ammonio-sulphuricum, Ferri ammonio-sulphas, Alumen ammoniacale ferricum.—Ammonio-ferric sulphate, Ammonio-ferric alum, Iron alum, E.; *Sulfate de fer et d'ammoniaque, Sulfate ferrique ammoniacal, Alun de fer ammoniacal,* Fr.; *Ferriammoniumsulfat, Schwefelsaures Eisenoxyd-Ammonium, Ammoniakalischer Eisenalaun,* G.

Formula, $NH_4Fe(SO_4)_2 + 12H_2O$ or $(NH_4)_2Fe_2(SO_4)_4 + 24H_2O$. Molecular weight, 478.69 or 957.38.

It should contain in the unefflorescd condition 99.5 per cent. of pure salt, and be kept in well-stoppered bottles, protected from light.—U. S.

Preparation.—The salt may be prepared by mixing equivalent quantities of ammonium sulphate and solution of ferric sulphate while hot, and setting aside to crystallize. The crystals are washed quickly with cold water, and dried on bibulous paper in the air. The mother-liquor yields a second crop of crystals on concentration.

Properties.—This salt crystallizes like alum in regular octahedrons, which are transparent and colorless or of a pale-amethyst or violet color, particularly if crystallized from a solution containing a little free acid. They have the specific gravity 1.712, are inodorous, of an acid and strongly astringent taste, and efflorescent on exposure to air. On the application of heat, it melts, parts with its water of crystallization, and is further decomposed, leaving ultimately a light-brown or red-brown residue. The salt is insoluble in alcohol and ether; at 25° C. (77° F.) it requires 2.7 parts, and at the boiling temperature 0.8 part, of water for solution. The aqueous solution has an acid reaction and is of a brownish-yellow color, which gradually changes to red, a basic salt being afterward deposited, and the decomposition being hastened by continued boiling of the solution. This shows the chemical reactions of ferric salts, sulphuric acid, and ammonia.

Tests.—If the solution be boiled with an excess of potassium hydroxide solution, and the colorless alkaline filtrate heated with an excess of ammonium chloride, or neutralized with hydrochloric acid and again rendered alkaline by ammonia, it should not yield a white gelatinous precipitate of aluminum hydroxide. The Pharmacopœia requires an amount of ferric sulphate corresponding to at least 11.5 per cent. of metallic iron, the method of titration and the quantities used being exactly the same as in the case of FERRIC CITRATE (which see); 11.5 Cc. of tenth-normal sodium thiosulphate solution should be required, corresponding to 11.5 per cent. of metallic iron. Silver nitrate solution added to 30 Cc. of the salt (1 in 20), acidulated with 3 Cc. of nitric acid, should not produce any turbidity (absence of chlorides).

Action and Uses.—Ferric alum is employed in medicine for its astringency. It may be successfully used in the treatment of diarrhœa with anæmia, as it is not so irritating to mucous membranes as the subsulphate. A saturated solution may also be locally applied as a styptic. The internal dose is from 5 to 10 grains (0.30–0.60 Gm.), 3 times daily.

FERRI ET AMMONII TARTRAS, *U. S.*—Iron and Ammonium Tartrate.

Ferri ammonio-tartras, Ferrum tartaricum ammoniatum.—Ammonio-ferric tartrate, Ammonio-tartrate of iron, E.; *Tartrate de fer et d'ammoniaque, Tartrate ferrique ammoniacal,* Fr.; *Ferriammontartrat, Weinsaures Eisenoxyd-Ammonium,* G.

It should contain not less than 13 per cent. of metallic iron, and be kept in well-stoppered bottles, protected from light.—U. S.

Preparation.—Solution of ferric sulphate, 100 Cc.; tartaric acid, 29 Gm.; distilled water, 200 Cc.; ammonia water, water, of each a sufficient quantity. To 110 Cc. of ammonia water, previously diluted with 250 Cc. of cold water, add, while constantly stirring, the solution of ferric sulphate, previously diluted with 1300 Cc. of cold water. When the precipitate has subsided, draw off the clear supernatant liquid by means of a syphon, then mix the precipitate intimately with about 1500 Cc. of cold water, again draw off the clear liquid, and repeat the washing in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then bring the precipitate on a wet muslin strainer, allow it to drain, and express the water as completely as possible. Dissolve one-half of the tartaric acid in the distilled water, neutralize the solution exactly with ammonia water, then add the other half of the tartaric acid, and dissolve it by the application of a gentle heat. Now bring in the moist ferric hydroxide, in successive portions, stirring constantly, and continuing the heat, which should not exceed 60° C. (140° F.), until the hydroxide is dissolved. Filter the solution while hot, evaporate it in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place.—U. S., 1890.

If 5 fluidounces of solution of ferric sulphate be used, it will require 662 grains of tartaric acid, 16 fluidounces of distilled water, and 5.5 fluidounces of ammonia water.

This formula is essentially that suggested by Prof. Procter (1841). By neutralizing one-half of the tartaric acid with ammonia water, ammonium tartrate is formed, which is converted into the acid salt by the addition of reserved tartaric acid. On digesting this with ferric hydroxide a solution is obtained which, by careful evaporation and drying upon plates, yields the official salt in scales.

Properties.—Iron and ammonium tartrate is in transparent, garnet-red, inodorous scales of a sweetish and slightly ferruginous taste, and yields a rust-colored powder. The Pharmacopœia permits the salt if of a reddish-brown color. In dry air it is permanent; in a moist atmosphere it is hygroscopic, but scarcely deliquescent. When heated, it gives off water and ammonia, is then charred, with the odor of burning sugar, and finally leaves a residue of ferric oxide. The salt is not soluble in alcohol or ether, but dissolves slowly and freely in glycerin and water. The latter solution is neutral to test-paper, is darkened but not precipitated by ammonia or by cold solutions of fixed alkalies or their carbonates, and is not colored blue by potassium ferrocyanide unless acidulated. When acidulated with hydrochloric acid and mixed with potassium acetate, potassium bitartrate is precipitated, When heated with potassium hydroxide solution in excess, a red-brown precipitate of ferric hydroxide is deposited, ammonia is given off, and the colorless fil-

trate, when cooled and strongly acidulated with acetic acid, yields a white crystalline precipitate of potassium bitartrate.

Tests.—The ash obtained on incineration should not have an alkaline reaction; this test readily distinguishes this salt from the next. The amount of iron present is determined volumetrically in the same manner as in the case of FERRIC CITRATE (which see), 0.555 Gm. of the salt requiring not less than 13 Cc. of the tenth-normal volumetric solution, representing 13 per cent. of iron.

Action and Uses.—This remedy may be employed as are the other mildly astringent preparations of iron in doses of from 10 to 30 grains (0.60–2 Gm.), preferably in solution.

FERRI ET POTASSII TARTRAS, *U. S.*—Iron and Potassium Tartrate.

Ferrum tartaratum, Br.; *Ferri potassio-tartras, Ferri-Kalium tartaricum, Ferrum tartarisatum.—Potassio-ferric tartrate, Tartarated (tartarized) iron, Ferro-tartrate of potassium*, E.; *Tartrate de fer et de potasse, Tartrate ferrico-potassique, Tartre chalybé, Tartre martial*, Fr.; *Kaliumferritartrat, Weinsaures Eisenoxyd-Kali, Eisenweinstein*, G.

It should contain not less than 15 per cent. of metallic iron, and be kept in well-stoppered bottles, protected from light.—U. S.

Preparation.—Solution of ferric sulphate, 100 Cc.; potassium bitartrate, 38 Gm.; distilled water, 300 Cc.; ammonia water, water, each a sufficient quantity. Prepare ferric hydroxide exactly as in Ferri et Ammonii Tartras. Then mix the potassium bitartrate, in a porcelain vessel, with the distilled water, heat the mixture on a water-bath to a temperature not exceeding 60° C. (140° F.), and gradually add the moist ferric hydroxide, stirring constantly until it is dissolved. Filter the liquid while hot, and let the filtrate stand in a cool, dark place for 24 hours. Then stir it well with a porcelain or glass spatula, so that the precipitate which has formed in it may be thoroughly incorporated with the liquid. Now add, very cautiously, just sufficient ammonia water to dissolve the precipitate, evaporate the solution in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place.—U. S., 1890,

If 5 fluidounces of solution of ferric sulphate be used, it will require 867 grains of acid potassium tartrate, 15 fluidounces of distilled water, and 5.5 fluidounces of ammonia water.

The formula of the British Pharmacopœia is like the above, the proportions used being solution of persulphate of iron 10 fluidounces, solution of ammonia 16 fluidounces, and acid potassium tartrate 3 ounces and 146 grains. As in the preceding case, ferric hydroxide is formed first, and this is used for saturating the potassium salt. A salt of the formula $K_6Fe_2(C_4H_4O_6)_6$ is probably formed first, which would yield somewhat more than 12 per cent. (Dulk found 12.78 per cent.) of ferric oxide; the British Pharmacopœia requires about 30; Soubeiran and Capitaine obtained 30.8 per cent. of ferric oxide, and regarded the salt as having the composition $K(FeO)C_4H_4O_6$. It is likely that different basic compounds may be formed by prolonged digestion. To render the salt perfectly and readily soluble in water, the U. S., 1890, directs the addition of a little ammonia water to the filtered solution before evaporation—a course recommended for this and analogous salts by G. H. C. Klie in 1876.

Properties and Tests.—In its physical properties, as well as in its behavior to solvents, alkalies, and potassium ferrocyanide, this salt resembles iron and ammonium tartrate, from which it differs in giving off a slight odor of ammonia when heated with potassium hydroxide solution, and, when incinerated, in leaving ash which has an alkaline reaction to test-paper and effervesces on the addition of hydrochloric acid. The Pharmacopœia demands not less than 15 per cent. of metallic iron, which is determined exactly as directed under FERRI CITRAS (which see), 0.555 Gm. of the salt requiring not less than 15 Cc. of tenth-normal sodium thiosulphate solution.

Tartarus ferratus, as above stated, is made into balls, which in France are known as *boules de Mars* and *boules de Nancy*, and, dissolved in hot water, are added to baths as a substitute for natural chalybeate waters. It is given internally in carbonated water, sherry wine, or syrup.

Action and Uses.—Because of its richness in iron, freedom from astringency, and

mild taste, this is one of the best salts of iron to employ. It rarely causes constipation, and is not very liable to produce gastric irritation. It is usually given in solution in the dose of from 5 to 10 grains (0.30–0.60 Gm.).

FERRI ET QUININÆ CITRAS, *U. S., Br.*—Iron and Quinine Citrate.

Chininum ferro-citricum, P. G.; *Citrate de fer et de quinine*, Fr.; *Ferrichinincitrat, Eisenchinincitrat, Citronensaures Eisen-Chinin*, G.

It should contain not less than 11.5 per cent. of quinine and 13.5 per cent. of metallic iron.—U. S.

Preparation.—Ferric citrate, 85 Gm.; quinine, dried at 100° C. (212° F.) to a constant weight, 12 Gm.; citric acid, 3 Gm.; distilled water, a sufficient quantity to make 100 Gm. Dissolve the ferric citrate in 160 Cc. of distilled water by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the quinine and citric acid, previously triturated with 20 Cc. of distilled water, and stir constantly until the quinine is dissolved. Lastly, evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place.—U. S., 1890.

To make 2 avoirdupois ounces of this compound dissolve 744 grains of ferric citrate in 3½ fluidounces of warm distilled water; to the solution add 105 grains of quinine dried at 100° C., and 26 grains of citric acid previously triturated with 3 fluidrachms of distilled water. When the quinine has all been dissolved evaporate as directed above.

The British Pharmacopœia directs to prepare ferric hydroxide from 9 fluidounces of solution of ferric sulphate as described under Ferri et Ammonii Tartras; the ferric hydroxide is then dissolved in 6 ounces and 60 grains of citric acid, dissolved by warming on a water-bath in an equal weight of water. In this solution is then dissolved quinine obtained by adding a slight excess of ammonia water to a solution of 2 ounces of quinine sulphate in 8 times its weight of distilled water and 3 fluidounces of diluted sulphuric acid, and washing the precipitate with 3 pints of distilled water. The mixture is then cooled, and to it are added, in small quantities at a time with brisk stirring, 3 fluidounces of solution of ammonia diluted with 4 fluidounces of distilled water. The quinine which separates on each addition of ammonia water is allowed to dissolve before the next addition. The solution is finally filtered. evaporated, and dried on glass plates at 37.8° C. (100° F.).

The British Pharmacopœia preparation corresponds closely to the next following compound in the subsequent addition of ammonium citrate, by which the physical properties of the resulting scales are changed.

The corresponding salt of the German Pharmacopœia again differs in containing, besides quinine, both ferric and ferrous salt, but no ammonia; no process is given in the last P. G., but in the preceding edition it was made by digesting powdered iron 3 parts with citric acid 6 parts and water 500 parts, adding afterward quinine 1 part, freshly precipitated by sodium hydroxide solution from 1.3 parts of quinine sulphate; the solution was then evaporated and scaled.

Properties.—The product of the first process is in transparent, inodorous scales of a yellowish-green-brown to reddish-brown color, varying according to their thickness. When heated to near redness, like other citrates it emits fumes having the odor of burnt sugar, and it finally leaves a brown ash free from alkaline reaction to test-paper. The salt, according to the U. S. P., is slowly deliquescent in damp air; it dissolves slowly in cold, more readily in hot, water, is slightly soluble in alcohol, and insoluble in ether; its solubility diminishes with age. The solution is slightly acid to test-paper, has a bitter and mildly chalybeate taste, and yields with tannin a grayish-black precipitate consisting of the mixed tannates of iron and quinine. On the addition of ammonia the liquid darkens in color, yields a white curdy precipitate of quinine, and the filtrate gives a blue precipitate with potassium ferrocyanide after the addition of hydrochloric acid. The solution of the salt on being heated with excess of potassium hydroxide solution gives a precipitate of ferric hydroxide and quinine, without evolving vapors of ammonia, and the filtrate after the addition of calcium chloride, again filtering, and then boiling, yields a white granular precipitate of calcium citrate. Another portion of the filtrate, acidulated with

acetic acid and allowed to stand for some time, should not deposit a crystalline white precipitate (absence of tartrate).

The product of the British Pharmacopœia corresponds with the behavior and tests described above, except that it is readily soluble in cold water; it is of a greenish-golden-yellow color, and in the air somewhat deliquescent.

Tests.—Dissolve 1.11 Gm. of the iron and quinine citrate in a capsule, with the aid of a gentle heat, in 20 Cc. of water. Transfer the solution, together with the rinsings of the capsule, to a separating funnel, allow the liquid to become cold, then add 5 Cc. of ammonia water, and 10 Cc. of chloroform, and shake. Allow the liquids to separate, remove the chloroform layer, and shake the residuary liquid twice more with 10 Cc. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.1276 Gm. (corresponding to at least 11.5 per cent. of dried quinine), and should correspond to the reactions and tests of quinine (see QUININA). Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, and allow it to cool. Then dilute it with water to the volume of 50 Cc., transfer 25 Cc. of the liquid to a glass-stoppered bottle (having a capacity of about 100 Cc.), add 2 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour at a temperature of 40° C. (104° F.). After it has been allowed to cool, it should require not less than 13.5 Cc. of tenth-normal sodium thiosulphate solution before the color of the liquid is discharged (each Cc. of the volumetric solution indicating 1 per cent of metallic iron).—U. S.

5 Gm. dissolved in 45 Cc. of water, and made alkaline with a slight excess of ammonia water, should yield a residue, on extracting repeatedly with ether and evaporating the latter, of 0.75 Gm. of quinine dried thoroughly at 120° C. (248° F.). This should dissolve almost entirely in purified ether and leave but a minute residue when burned.—Br. According to the P. G., 10 Gm. treated in a similar manner should yield at least 0.9 Gm. of quinine dried at 100° C.

The salt should contain at least 15 per cent. Br., 11.5 per cent. U. S., 9 per cent. P. G., of quinine.

The pharmacopœial method prescribed for the determination of quinine and iron is identically that proposed by F. B. Power, and possesses the great advantage of using the same weighed sample for both operations; although 12 per cent. of quinine is directed in the formula, a little allowance for shortage is very properly made, owing to the variable quantity of water present. The amount of anhydrous ferric citrate represented by 13.5 per cent. of metallic iron is 59.14 per cent.

Substitution of cinchonine for quinine in the salt may be detected by tests characteristic of these alkaloids. Quinine is soluble in 23 parts, cinchonine in 526 parts of ether. Toward polarized light the former is lævorotatory; the latter, dextrorotatory.

Action and Uses.—This preparation may be employed during convalescence from acute diseases and other conditions in which the two bases are indicated. The ordinary dose is 5 grains (0.30 Gm.), which may be increased if needed. It is best administered in pill-form.

FERRI ET QUININÆ CITRAS SOLUBILIS, *U. S.*—Soluble Iron and Quinine Citrate.

Preparation.—Ferric citrate, 85 Gm.; quinine, dried at 100° C. (212° F.) to a constant weight, 12 Gm.; citric acid, 3 Gm.; ammonia water, distilled water, each a sufficient quantity, to make 100 Gm. Dissolve the ferric citrate in 160 Cc. of distilled water, by heating on a water-bath, at a temperature not exceeding 60° C. (140° F.). To this solution add the quinine and citric acid previously triturated with 20 Cc. of distilled water, and stir constantly until the quinine is dissolved. Then add gradually, and with constant stirring, 50 Cc., or a sufficient quantity, of ammonia water, so that after the addition of each portion of the latter the precipitated quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and

spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place.—U. S., 1890.

This preparation differs from the preceding in the addition of ammonia water prior to evaporation of the liquid, whereby the solubility of the scale compound is vastly increased; whenever iron and quinine citrate is to be dispensed in form of solution, the "soluble" should be used; whereas the official salt without ammonia is to be employed for pill-masses, tablet-form, etc., on account of its less tendency to absorb moisture on exposure to air.

Properties and Tests.—Soluble iron and quinine citrate occurs in thin transparent scales of a greenish-golden-yellow color, and is readily soluble in cold water; if a portion of the salt be heated with potassium hydroxide solution, vapor of ammonia is evolved. In all other respects it corresponds to the preceding compound, and should contain exactly the same amount of quinine and iron when assayed by the method there prescribed.

Action and Uses.—This preparation is best prescribed in solution in doses of from 5 to 10 grains (0.30–0.60 Gm.). Its uses are indicated under FERRI ET QUININÆ CITRAS (which see).

FERRI ET STRYCHNINÆ CITRAS, *U. S.*—Iron and Strychnine Citrate.

Citrate de fer et de strychnine, Fr.; *Citronensaures Eisen-Strychnin*, G.

It should contain not less than 0.9 nor more than 1 per cent. of strychnine, and not less than 16 per cent. of metallic iron; it should be kept in well-stoppered bottles protected from light.—U. S.

Preparation.—Iron and ammonium citrate, 98 Gm.; strychnine, 1 Gm.; citric acid, 1 Gm.; distilled water, 120 Cc.; to make 100 Gm. Dissolve the iron and ammonium citrate in 100 Cc. of distilled water, and the strychnine, together with the citric acid, in 20 Cc. of distilled water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in well-stoppered bottles, in a dark place.—U. S., 1890.

A small quantity of this scale salt may be prepared by dissolving 490 grains of iron and ammonium citrate in 1½ fluidounces of distilled water, adding a solution of 5 grains of strychnine and 5 grains of citric acid in 1 fluidrachm of distilled water, and evaporating as directed.

This is simply a mixture of strychnine citrate with ammonio-ferric citrate, scaled in precisely the same manner as the other iron preparations.

Properties.—The salt closely resembles ammonio-citrate of iron in appearance, and has the same behavior to reagents as described above, but differs from it in the distinctly bitter taste and in the white precipitate produced by ammonia, the precipitate being soluble in boiling alcohol, from which, if the solution is sufficiently concentrated, crystals will be obtained giving the peculiar reactions of strychnine. The alkaloid will also be obtained by adding potassium hydroxide solution to the salt, agitating with chloroform, and evaporating the chloroform solution.

Tests.—Dissolve 4.44 Gm. of iron and strychnine citrate in a glass separator in 15 Cc. of water, add 5 Cc. of ammonia-water and 10 Cc. of chloroform, and shake at intervals for at least 10 minutes. Allow the liquids to separate, remove the chloroform layer, and shake the residuary liquid twice more with 10 Cc. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.04 Gm., nor more than 0.0444 Gm. (corresponding to not less than 0.9, nor more than 1 per cent. of strychnine), and should respond to the reactions and tests of strychnine (see STRYCHNINA). Heat the aqueous liquid, from which the strychnine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, and allow it to cool. Then dilute it with water to the volume of 100 Cc., transfer 25 Cc. of the liquid to a glass-stoppered bottle (having the capacity of about 100 Cc.), add 2 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour at a temperature of 40° C. (104° F.). After it has been allowed to cool it should require not less than 32 Cc. of tenth-normal sodium thiosulphate solution before the color of the liquid is dis-

charged (each Cc. of the volumetric solution indicating 0.5 per cent. of metallic iron).—U. S.

These tests, suggested by F. B. Power, demand about 1 per cent. of strychnine, and practically 79 per cent. of anhydrous ferric citrate, corresponding to 16 per cent. of metallic iron. The limits of 0.9 and 1 per cent. are based on the variable quantity of water present. Dr. Squibb has pointed out that the solution of the salt is not permanent, but soon begins to form a deposit containing much strychnine, which is likely to lead to alarming if not dangerous effects.

Action and Uses.—This preparation may be employed in those conditions in which iron and strychnine are usually indicated, namely, in cases of nervous debility with anæmia, as in convalescence. It has the disadvantage that the dose of one ingredient cannot be increased or diminished without affecting the other agent also. The dose is from 3 to 5 grains (0.2–0.30 Gm.), best given in pill-form, as its solution is said to be unstable.

FERRI HYDROXIDUM, *U. S.*—Ferric Hydroxide.

Ferri oxidum hydratum, U. S., 1890. *Ferri peroxidum.—Hydrated oxide of iron; Moist peroxide of iron*, E.; *Sesquioxide (Peroxyde) de fer hydraté humide; Hydrate de peroxyde de fer gélatineux*, Fr.; *Feuchtes Eisenoxydhydrat*, G.

Formula of freshly prepared ferric hydroxide, $Fe(OH)_3$ or $Fe_2(OH)_6$. Molecular weight, 106.14 or 212.28.

Preparation.—Solution of ferric sulphate, 100 Cc.; ammonia-water, 138 Cc.; water, a sufficient quantity. To the ammonia-water, previously diluted with 500 Cc. of cold water, add, with constant stirring, the solution of ferric sulphate, previously diluted with 1000 Cc. of cold water. As soon as the precipitate has subsided, draw off the clear liquid by means of a siphon, then mix the precipitate intimately with about 1000 Cc. of cold water, again draw off the clear liquid after subsidence of the precipitate, and repeat this operation until a portion of the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally transfer the precipitate to a wet muslin strainer, and, after it has drained, mix it with sufficient cold water to make the mixture weigh 300 Gm.

When ferric hydroxide is to be made in haste for use as an antidote, the washing may be performed more quickly, though less perfectly, by bringing the precipitate at once on a wet muslin strainer, pressing forcibly with the hands until no more liquid passes, and then adding sufficient water to make the whole weight about 300 Gm.

The official ferric hydroxide may also be prepared by adding a mixture of 3½ fluidounces of solution of ferric sulphate and 2 pints of water, with constant stirring, to 5 fluidounces of ammonia water previously diluted with 20 fluidounces of water.

The reaction is one of double decomposition; thus, $Fe_2(SO_4)_3+6NH_4OH=Fe_2(OH)_6+3(NH_4)_2SO_4$. The ammonium sulphate formed is soluble and removed by washing. The brown ferric hydroxide remaining has the formula given. It combines very easily with weak acids, and for this reason is an effectual antidote to arsenic, which forms with it an insoluble salt. It cannot be dried without losing water and being converted into oxyhydrate of the formula $Fe_2O_2(OH)_2$, which has a more decided reddish tint and combines less readily with acids, and not at all with arsenous acid. The compound of this composition was official in the British Pharmacopœia until 1898, and was obtained by heating the hydroxide not over 100° C. (212° F.). The loss of water from the official hydroxide is retarded by keeping it mixed with water in the form of a magma; but after some time it parts with half its water of hydration, forming the reddish-brown ferric oxyhydrate, $Fe_2O_3.Fe_2(OH)_6$, which has lost the power of combining with weak acids, such as arsenous or acetic acid. A similar effect may be wholly or partly obtained during the preparation of the hydroxide if the mixture be allowed to become hot. Its effectiveness as an antidote is due to two conditions—the making of the hydroxide at the *ordinary*, not at an elevated, temperature, and its *recent* preparation; the magma with water should be smooth, not granular, and should be easily soluble in acetic acid.

Action and Uses.—Ferric hydroxide is rarely employed in internal medicine. It is largely used, however, as an antidote in poisoning by arsenic (see FERRI HYDROXIDUM CUM MAGNESII OXIDO). It should always be freshly prepared and as free from ammonia-water as possible. It is thought by some, however, that traces of ammonia aid in its efficiency as an antidote. As an antidote it should be given *ad libitum*.

FERRI HYDROXIDUM CUM MAGNESII OXIDO, *U. S.*—Ferric Hydroxide with Magnesium Oxide.

Ferri Oxidum Hydratum cum Magnesia, U. S., 1890. *Antidotum Arsenici.—Arsenic antidote*, E.; *Contre-poison de l'arsenic*, Fr.; *Gegengift des Arseniks*, G.

Preparation.—Solution of ferric sulphate, 40 Cc.; magnesium oxide, 10 Gm.; water, a sufficient quantity. Mix the solution of ferric sulphate with 125 Cc. of water, and keep the liquid in a well-stoppered bottle. Rub the magnesium oxide with cold water to a smooth and thin mixture, transfer this to a bottle capable of holding about 1000 Cc., and fill it with water to about three-fourths of its capacity. When the preparation is wanted for use, shake the magnesium oxide mixture to a homogeneous, thin magma, add it gradually to the diluted ferric sulphate, and shake them until a uniform smooth mixture results.

Note.—The diluted solution of ferric sulphate and the mixture of magnesium oxide with water should always be kept on hand, ready for immediate use.—U. S.

Using wine measure, it will be found convenient to keep on hand, in separate bottles, 2 fluidounces of ferric sulphate solution, diluted with 6 fluidounces of water, and 225 grains of magnesium oxide made into a smooth mixture with 30 fluidounces of water; the amount of water to be mixed with the magnesium oxide will be found quite sufficient.

The magnesia is used in excess, more than is necessary for separating all the ferric hydroxide, and the mixture is prevented from becoming heated by the previous diffusion of the magnesia in water. Neither filtration nor straining is requisite, the compounds of the mixture being ferric and magnesium hydroxides and magnesium sulphate, none of which has any caustic or otherwise injurious effect, nor forms a soluble compound with arsenic. The mixture being made only when needed, the ferric hydroxide is in that condition in which it readily combines with arsenous acid and has not become inert for the purpose by long keeping.

Uses.—This remedy is employed exclusively as an antidote in arsenical poisoning. It should always be freshly prepared and given in large quantity. It is certain that this mixture is a more efficient antidote to arsenic than either of its ingredients would be alone.

FERRI HYPOPHOSPHIS, *U. S.*—Ferric Hypophosphite.

Ferrum hypophosphorosum.—Hypophosphite of iron, E.; *Hypophosphite de fer*, Fr.; *Ferrihypophosphit, Unterphosphorigsaures Eisenoxyd*, G.

Formula, $Fe(PH_2O_2)_3$. Molecular weight, 249.09.

It should contain not less than 98 per cent. of pure salt, and be kept in well-stoppered bottles.—U. S.

Preparation.—A solution of sodium hypophosphite which is free from carbonate is added to a solution of ferric chloride or ferric sulphate, which should not contain an excess of acid. The precipitate is well washed with distilled water and dried with a moderate heat. It is a process of double decomposition between the sodium and ferric salts. The presence of carbonate in the former would contaminate the salt with a corresponding quantity of ferric hydroxide, while an excess of acid would occasion loss by preventing the ferric hypophosphite from being precipitated. By this method a slight loss is occasioned by the partial solubility of the freshly precipitated ferric hypophosphite in water.

Moerk suggests to prepare the salt as follows: Place 30 Gm. of calcium hypophosphite into a flask with 100 Cc. of distilled water; add gradually 49.5 Gm. of ferric chloride solution, shaking well after each addition. Allow the mixture to stand 3 days with frequent agitation, then filter, and wash until all calcium has been removed. This is said to yield about 93 per cent. of a very pure salt, based upon the quantity of ferric chloride used.

Properties.—Ferric hypophosphite is a white or grayish powder, inodorous, nearly tasteless, slightly soluble in water, more so in hypophosphorous acid, but freely so in hydrochloric acid. Like other insoluble or sparingly soluble ferric salts, it dissolves in solutions of an alkali citrate, with a green color. It is readily oxidized by nitric acid and other oxidizing agents, and when heated in the dry state evolves inflammable hydrogen phosphide and leaves ferric pyrophosphate. Its formula is given above; it contains, in addition, water of hydration, the amount of which has not been determined.

Tests.—If to 0.5 Gm. of the salt 5 Cc. of acetic acid be added, no effervescence should occur (absence of carbonate), and if the mixture be subsequently heated to

boiling, the filtrate, upon cooling, should afford no turbidity with ammonium oxalate test-solution (absence of calcium). If 0.5 Gm. of the salt be boiled with 10 Cc. of sodium hydroxide test-solution, a reddish-brown precipitate is produced, and if to the filtrate from the latter slightly acidulated with hydrochloric acid magnesia mixture be added, and subsequently an excess of ammonia-water, no crystalline precipitate should be produced (absence of phosphate). If 1 Gm. of the salt be dissolved in 25 Cc. of boiling water, with sufficient hydrochloric acid, and precipitated with slight excess of ammonia-water, the filtrate should be colorless, and, after acidifying with hydrochloric acid, should not be colored or made turbid by an equal volume of fresh hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after adding ammonia to alkalinity (absence of heavy metals).

The volumetric assay of the salt by potassium permanganate solution is defective and has been dropped from the U. S., 1900, in which no method is now given.

See under Calcii Hypophosphis for reference to Jowett's criticism of the permanganate method of titration. Jowett tests for phosphite in ferric hypophosphite, by shaking up 0.5 Gm. of the salt with 10 Cc. of a 5 per cent. solution of sodium hydroxide, filtering, acidifying with acetic acid, and adding lead acetate solution. He was unable to devise a method of determining the amount of hypophosphite without introducing the error due to phosphite, but this could be partly remedied by noting the amount of lead phosphite precipitate in the above test. His method of assay is to oxidize 0.3 Gm. of the salt, then add 0.5 Gm. of sodium citrate, and finally excess of sodium hydroxide solution. The precipitate is washed and the iron in it determined iodometrically, and the phosphate in the filtrate by the usual methods. The salt prepared from ferrous compounds contains some ferrous hypophosphite, which would cause an error in the official method of titration, due to iron in the ferrous state.

Action and Uses.—Ferric hypophosphite has been recommended in the treatment of anæmias associated with a depressed condition of the central nervous system. As it does not possess the virtues of phosphorus, it is highly probable that this remedy is of much less value than was formerly supposed. The dose is from 5 to 10 grains (0.30–0.60 Gm.). It is usually administered in the form of a syrup.

FERRI LACTAS.—Ferrous Lactate.

Ferrum lacticum, P. G.; *Lactate of iron*, E.; *Lactate ferreux, Lactate de fer*, Fr.; *Eisenlactat, Milchsaures Eisenoxydul*, G.

Formula, $Fe(C_3H_5O_3)_2 3H_2O$. Molecular weight, 285.88.

Preparation.—This compound has been omitted from the U. S., 1900. It may be prepared by digesting iron filings with lactic acid until action ceases, filtering, and crystallizing. It may also be prepared from crystalline calcium lactate, $Ca(C_3H_5O_3)_2 + 5H_2O$, obtained in the preparation of lactic acid, by dissolving 31 parts of it in 750 or 800 parts of water, and mixing this with a solution of 28 parts of crystallized ferrous sulphate; by double decomposition ferrous lactate is formed and remains in solution, while most of the calcium sulphate is precipitated, the remainder being removed by mixing the liquid with one-tenth volume of alcohol; the filtrate is finally evaporated and crystallized. A similar process has been adopted by the French Codex.

Both these processes involve considerable evaporation, which may be avoided, according to Pagenstecher (1842), by mixing an alcoholic solution of sodium lactate with a freshly prepared solution of ferrous chloride, when nearly the whole of the ferrous lactate will crystallize out, and the alcohol used may be recovered by distilling the mother-liquor. Thus prepared, the salt is less prone to oxidation.

Properties.—Ferrous lactate forms a greenish-white or yellowish crystallized powder or crusts consisting of small needle-shaped crystals containing 19 per cent. of water of crystallization, and having a slight peculiar odor, a sweet and mild chalybeate taste, and a slightly acid reaction. The dry salt is nearly permanent in dry air, but in a damp atmosphere is gradually converted into ferric salt. It is almost insoluble in cold alcohol, but may be crystallized from boiling diluted alcohol; it dissolves slowly at 15° C. (59° F.) in 40 parts, P. G., of water, and in 12 parts of boiling water, the solutions being of a greenish-yellow color, and it is freely soluble with a green color in solutions of alkali citrates. On the application of heat it turns brown and black, and then, with frothing, emits white acid vapors having the odor of burnt sugar, and finally

leaves brownish-red ferric oxide, amounting to about 27.7 per cent. The aqueous solution yields a dark-blue precipitate with potassium ferricyanide, and a light blue one with potassium ferrocyanide; in contact with the air it speedily turns brown, forming ferric lactate, and then yields at once a dark-blue precipitate with potassium ferrocyanide. The salt, boiled for 15 minutes with an excess of nitric acid diluted with an equal bulk of water, yields on cooling white granules of mucic acid.

Two varieties of ferrous lactate occur in commerce, one in well-defined crystalline crusts, and another in the form of a crystalline powder. The first named is to be preferred for pharmaceutical purposes; it is, as a rule, more soluble and less likely to become oxidized.

Ferrous lactate should be kept in well-stoppered bottles.

Tests.—A 2 per cent. aqueous solution of the salt should not afford, with lead acetate test-solution, or after acidulation with hydrochloric acid, with hydrogen sulphide test-solution, more than a whitish opalescence (limit or absence of sulphate, chloride, citrate, tartrate, malate, etc., and of foreign metals). The aqueous solution, acidulated with nitric acid, should not afford more than a slight opalescence with barium chloride test-solution, or with silver nitrate test-solution (limit of sulphate or chloride). If 25 Cc. of the aqueous solution (1 in 50) be boiled for a few minutes with 5 Cc. of diluted sulphuric acid, then an excess of potassium or sodium hydroxide test-solution added, the filtrate, after the addition of a few drops of alkaline cupric tartrate solution, and heated to boiling, should not afford a red precipitate (absence of sugar). If a portion of the salt be triturated with strong sulphuric acid, no odor of butyric acid or gas should be evolved (absence of carbonate), and the mixture, after standing for some time, should not assume a brown color (absence of sugar, gum, or other organic impurities). If 1 Gm. of the salt, contained in a porcelain crucible, be moistened with nitric acid, and carefully ignited, it should leave a residue of ferric oxide weighing not less than 0.270 nor more than 0.278 Gm. This residue should not have an alkaline reaction to litmus-paper, nor yield anything soluble in water (absence of foreign salts).

Action and Uses.—This salt has been employed to some extent in the treatment of chlorosis. It is a mild, non-astringent chalybeate, and because of its feeble taste may be given without difficulty. The dose is stated to be from 1 to 20 grains (0.06–1.3 Gm.). It may be dissolved in hot syrup to the extent of 4 grains to the fluidounce, but should not be dissolved in water, owing to its liability to oxidation. The ordinary dose of the syrup is from 2 to 4 fluidrachms (8–16 Cc.).

FERRI OXIDUM SACCHARATUM.—Saccharated Ferric Oxide.

Ferrum oxydatum saccharatum, P. G.—*Saccharated oxide of iron, Saccharated iron*, E.; *Saccharate de fer, Saccharure d'oxyde de fer soluble*, Fr.; *Eisenzucker, Lösliches Eisenoxyd*, G.

Preparation.—To a mixture of 30 parts of solution of ferric chloride (specific gravity, 1.281) and 150 parts of water add gradually and with frequent stirring a solution of 26 parts of sodium carbonate in 150 parts of water until precipitation has been completed; the precipitate is repeatedly washed with water by decantation until all chlorides have been removed, then drained and expressed on a muslin filter. 50 parts of powdered sugar and 5 parts of solution of sodium hydroxide (specific gravity, 1.70) are added to the residue, the mixture is heated to perfect solution, and then evaporated to dryness and powdered; finally sufficient powdered sugar is added to make the weight of the finished product 100 parts.—P. G.

Properties.—A small quantity of sodium hydroxide is essential to cause solution of the ferric hydroxide by the sugar; without it, the hydroxide does not dissolve. The substance is a reddish-brown powder, having a sweet and mild chalybeate taste, soluble in 20 parts of hot water with feeble alkaline reaction. The usual reactions of iron are inhibited; no precipitate of iron is produced by phosphates, carbonates, arsenates, ferrocyanide of potassium, or tannic acid. All the iron is precipitated by ammonium sulphide as ferrous sulphide. After addition of hydrochloric acid, potassium ferrocyanide produces slowly a dark-blue precipitate. An acidified solution precipitates insoluble iron saccharate, which is decomposed by more acid, forming an iron salt.

If 1 Gm. of saccharated iron oxide be dissolved in 10 Cc. of diluted sulphuric acid, and, after disappearance of the brown color, dilute solution of potassium permanganate be added until a red tint is produced of a few moments' duration, and then 2 Gm. of

potassium iodide be added and the mixture allowed to stand in a stoppered bottle 1 hour at ordinary temperature, it should require 5–5.3 Cc. of tenth-normal sodium thiosulphate to titrate the iodine separated by oxidation, corresponding to 2.8–2.97 per cent. of metallic iron (each Cc. of the thiosulphate solution represents 0.0056 Gm. of iron).

Action and Uses.—The saccharated oxide of iron is said to be an efficient ferruginous preparation, and is believed by some to be the best antidote in arsenical poisoning. A syrup of the soluble oxide of iron may be prepared by dissolving 1 part of it in 1 part of distilled water and 1 of syrup, and given in quantities representing from 3 to 10 grains (0.2–0.60 Gm.) of the salt, although smaller doses usually produce better results.

FERRI PHOSPHAS SOLUBILIS, *U. S.*—Soluble Ferric Phosphate.

Ferri phosphas, U. S. 1880.—*Ferri et sodii citro-phosphas; Ferrum phosphoricum cum natrio citrico.—Soluble phosphate of iron, Sodio-ferric citro-phosphate*, E.; *Citro-phosphate de fer et de soude*, Fr.; *Natriumferricitrophosphat*, G.

It should contain not less than 12 per cent. of metallic iron, and be kept in well-stoppered amber bottles, away from light.—U. S.

Preparation.—Ferric citrate, 50 Gm.; sodium phosphate, uneffloresced, 55 Gm.; distilled water, 100 Cc. Dissolve the ferric citrate in the distilled water by heating on a water-bath. To this solution add the sodium phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that when dry the salt may be obtained in scales. Keep the product in dark, amber-colored, well-stoppered bottles.—U. S., 1890.

To prepare a small quantity of soluble ferric phosphate, 1 avoirdupois ounce of ferric citrate should be dissolved in 2 fluidounces of hot distilled water; to the solution add 481 grains of uneffloresced sodium phosphate and proceed as stated above.

The official title of this preparation serves to distinguish it at once from other commercial varieties of ferric phosphate which are insoluble in water. The proportion of the two salts is based upon the assumption that carefully prepared ferric citrate in scales contains 10 molecules of water, and has the formula $Fe_2(C_6H_5O_7)_2 + 10H_2O$; it is important that uneffloresced sodium phosphate be used, as otherwise an excessive amount of the latter will cause the scales to become white on standing.

Properties and Tests.—Thin, bright-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air when excluded from light, but becomes dark and discolored on exposure to light. Freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt has a slightly acid reaction. With potassium ferrocyanide test-solution the solution affords a blue color, but does not yield a blue precipitate unless it has been acidulated with hydrochloric acid. If 1 Gm. of the salt be boiled with 15 Cc. of potassium or sodium hydroxide test-solution, a reddish-brown precipitate is produced; and if the colorless filtrate from the latter be strongly acidulated with hydrochloric acid, then magnesia mixture added, and subsequently a slight excess of ammonia water, an abundant white crystalline precipitate is produced. During the boiling with the alkali, no odor of ammonia should be evolved.

The Pharmacopœia requires 12 per cent. of metallic iron, which is determined in a manner exactly as given under Ferri Pyrophosphas Solubilis (which see), 0.555 Gm. of the salt requiring about 12 Cc of tenth-normal sodium thiosulphate solution. This is 2 per cent. more than is required for the similar salt, Ferri Pyrophosphas Solubilis.

Composition.—The exact composition of the soluble ferric phosphate cannot be stated, and it is possible that no less than four salts are present, viz., sodium and ferric phosphates and sodium and ferric citrates; if the interchange of acid radicals were complete, the chemical formula might be written as $Fe_2(PO_4)_2 2Na_2HC_6H_5O_7 + Aq$.

Action and Uses.—This salt possesses practically the properties of the other chalybeates. It has been employed in the treatment of the various menstrual disorders and of indigestion resulting from anæmia. The dose is from 5 to 10 grains (0.30–0.60 Gm.).

True Phosphates of Iron.—*Ferri phosphas*, Br.; *Ferrum phosphoricum.—Phosphate of iron, Ferroso-ferric phosphate*, E.; *Phosphate de fer, Phosphate ferroso-ferrique*, Fr.; *Ferroferriphosphat, Phosphorsaures Eisenoxydul-Oxyd*, G. $Fe_3(PO_4)_2.FePO_4.12H_2O$.—Dissolve 3 ounces

of ferrous sulphate in 30 ounces of boiling distilled water, and 2¾ ounces of sodium phosphate in a like quantity of water. When each solution has cooled to between 37.8° and 54.4° C. (100° and 130° F.), add the latter to the former, pouring in also a solution of ¾ ounce of sodium bicarbonate in a little distilled water. Mix thoroughly. Transfer the precipitate to a calico filter, and wash it with hot distilled water till the filtrate ceases to give a precipitate with barium chloride. Finally, dry the precipitate at a temperature not exceeding 48.9° C. (120° F.).—Br. This salt is employed in doses of from 5 to 10 grains (0.30–0.60 Gm.) for the same purposes as *Ferri Phosphas Solubilis.*

The mineral *vivianite*, which forms pale-blue crystals, is mainly ferrous phosphate. On bringing together solutions of ferrous sulphate and sodium phosphate a white precipitate of ferrous phosphate is produced, which on exposure and during the washing is oxidized, and acquires a more or less blue, greenish-blue, or grayish-blue color. During the reaction a portion of the sulphuric acid is set free, and retains phosphates of iron in solution, to obtain which sodium acetate is added, which, reacting with the free sulphuric acid, forms sodium sulphate and free acetic acid, in which the phosphates of iron are insoluble. Or the free acid may be nearly neutralized with sodium carbonate or bicarbonate, as directed above. The washing of the precipitate should be continued until the filtrate fails to give a reaction for sulphuric acid.

Thus prepared, phosphate of iron is a tasteless and inodorous bluish powder, varying somewhat in shade. It is insoluble in water, but dissolves in hydrochloric acid, yielding a yellow solution in which dark-blue precipitates are produced by both potassium ferrocyanide and ferricyanide. If the acid solution is treated with sufficient tartaric acid, and then with an excess of ammonia, no precipitate is produced, but on the addition of magnesium sulphate a white precipitate of ammonio-magnesium phosphate falls. When the powder is boiled with caustic soda the filtrate, after being neutralized, yields a yellow precipitate with silver nitrate. Both precipitates indicate phosphoric acid. The chemical composition varies to some extent, and is influenced by its exposure to the atmosphere while moist, the temperature at which it is dried, etc. The above formula is that of Rammelsberg. Wittstein obtained a somewhat different result. The British Pharmacopœia regards it as containing at least 47 per cent. of ferrous phosphate ($Fe_3(PO_4)_2 + 8H_2O$); 1 Gm. dissolved in hydrochloric acid should require for complete oxidation not less than 28.2 Cc. of the volumetric solution of potassium dichromate, which indicates 47 per cent. of the ferrous salt.

The salt should yield nothing to hot distilled water (insufficient washing), and the solution in hydrochloric acid should yield only a white turbidity of sulphur with hydrogen sulphide, but not a black (copper, etc.) or a yellow (arsenic) precipitate. The same solution, digested with bright copper, should not form a dark deposit of arsenic upon the metal.

Ferri phosphas albus.—Ferrum phosphoricum oxydatum.—Ferric phosphate, White phosphate of iron, E.; *Phosphate ferrique*, Fr.; *Ferriphosphat*, G. $Fe_2(PO_4)_2 + 4H_2O$. Molecular weight, 371.1.—On mixing 4 fluidounces of solution of ferric sulphate with a solution of 1 ounce of sodium acetate, and adding solution of sodium phosphate, a white precipitate of ferric phosphate is obtained. After washing and drying at 100° C. (212° F.) it is a white or yellowish-white tasteless powder having the composition stated, is decomposed by alkalies, and dissolves readily in dilute mineral acids, in citric and tartaric acids, and in alkali citrates, the latter solutions having a green color. The freshly precipitated and washed salt, mixed with water until the mixture contains 1 or 1.2 per cent. of ferric phosphate, has been used under the name of *Lac ferri, milk of iron.*

FERRI PYROPHOSPHAS SOLUBILIS, *U. S.*—Soluble Ferric Pyrophosphate.

Ferri pyrophosphas, U. S. 1880.—*Ferri et sodii citro-pyrophosphas, Ferrum pyrophosphoricum cum sodio citrico.—Pyrophosphate of iron with sodium citrate, Sodio-ferric citro-pyrophosphate*, E.; *Citro-pyrophosphate de fer et de soude*, Fr.; *Pyrophosphorsaures Eisenoxyd mit Citronensaurem Natron*, G.

It should contain not less than 10 per cent. of metallic iron, and be kept in well-corked amber bottles, away from light.—U. S.

Preparation.—Ferric citrate, 50 Gm.; sodium pyrophosphate, uneffloresced, 50 Gm.; distilled water, 100 Cc. Dissolve the ferric citrate in the distilled water by heating on a water-bath. To this solution add the pyrophosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistency of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark, amber-colored, well-stoppered bottles.—U. S., 1890.

As seen by the above formula, ferric citrate and sodium pyrophosphate are used in the proportion of equal weights; this change from the 1880 Pharmacopœia is based on

the recommendations of Lake and Power. In view of the insolubility in water of true ferric pyrophosphate, the addition of the word "soluble" to the official title was desirable.

On precipitating a solution of sodium pyrophosphate by ferric sulphate, a white precipitate of *ferric pyrophosphate*, $Fe_4(P_2O_7)_3$, is obtained, which, like other insoluble ferric salts, is readily soluble in alkali citrates, forming green solutions. Formerly, ammonium citrate was used for this purpose, but owing to the slow volatilization of the ammonia the salt gradually became insoluble.

Properties and Tests.—The salt is obtained in inodorous, transparent, apple-green scales, which are permanent in dry air when excluded from light, but turn dark on exposure to light. The salt has an acidulous, slightly saline, and scarcely chalybeate taste, and a slightly acid reaction, is insoluble in alcohol, but dissolves freely in water, yielding a greenish solution; this gives with potassium ferrocyanide a blue color, but no precipitate unless acidulated with hydrochloric acid. If 0.555 Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 10 Cc. of water, then 10 Cc. of hydrochloric acid, and subsequently 40 Cc. of water added, and, after the addition of 1 Gm. of potassium iodide, the mixture be allowed to stand for half an hour at a temperature of 40° C. (104° F.), and then allowed to cool, and mixed with a few drops of starch test-solution, it should require about 10 Cc. of tenth-normal sodium thiosulphate test-solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution indicating 1 per cent. of metallic iron).—U. S.

Like the soluble ferric phosphate, this preparation is evidently of a complex nature, and, as in all the scale compounds of iron, the amount of water of hydration is variable.

Composition.—Regarding the chemical composition of this and similar preparations, two views have been entertained. According to the one, they are double salts of ferric pyrophosphate and alkali citrate; according to the other, which has been advocated by Rother (1876), they should be regarded as mixtures of alkali-ferric pyrophosphate, $Fe_4(P_2O_7)_3 3Na_4P_2O_7$, with alkali-ferric citrate and ferric citrate. The formula given for the double pyrophosphate corresponds with that of Gladstone for sodio-ferric pyrophosphate, for which Fleitmann and Persoz (1848) gave the formula $Fe_4(P_2O_7)_3.2Na_4P_2O_7$.

Action and Uses.—This is an excellent ferruginous preparation because of its mild taste, free solubility, and large percentage of iron. It may be given either in pill or solution, in water or syrup. The dose is from 2 to 5 grains (0.12–0.30 Gm.).

FERRI SULPHAS, *U. S., Br.*—Ferrous Sulphate.

Ferrum sulfuricum, P. G.; *Ferrum vitriolatum purum, Vitriolum martis purum.*—*Sulphate of iron*, E.; *Sulfate (Protosulfate) de fer, Sulfate ferreux*, Fr.; *Ferrosulfat, Schwefelsaures Eisenoxydul*, G.

Formula of crystallized or precipitated ferrous sulphate, $FeSO_4 + 7H_2O$; molecular weight, 276.01; of exsiccated ferrous sulphate, approximately, $2FeSO_4 + 3H_2O$; molecular weight, 355.34.

It should contain not less than 99.5 per cent. of pure salt, and should not be effloresced. Keep well corked.—U. S.

Preparation.—For medicinal use, it should be prepared directly from sulphuric acid acting upon iron wire or clean iron filings in the presence of water, when hydrogen is evolved, ferrous sulphate remaining in solution: $Fe_2 + 2H_2SO_4$ yields $2H_2 + 2FeSO_4$. The salt is prone to oxidation if its chemically neutral solution is evaporated to crystallization, but in the presence of free sulphuric acid yields crystals which are far more permanent. This explains the necessity of having some free sulphuric acid in the liquid from which ferrous sulphate is crystallized. The crystals are collected upon a diaphragm, washed rapidly with a little water (according to the Fr. Cod. with a little alcohol) to remove the mother-liquor, and then dried. No process is given in the U. S. and Br. pharmacopœias for its preparation. Ferrous sulphate of the P. G. is identical in appearance with granulated ferrous sulphate (see below), and is not made by direct crystallization, but by pouring the solution into strong alcohol and washing the resulting granular product with alcohol.

Ferrous sulphate is obtained on a large scale from alum shale, and by roasting iron pyrites, exposing to the air, and exhausting the mass with water; also by passing solutions of copper sulphate over scraps of iron, whereby copper is precipitated, the iron entering into solution. It is also obtained as a by-product in various manufactures in

which sulphuric acid is used for the purpose of purifying certain products. The article thus obtained is usually impure and not fit for medicinal purposes, except for disinfecting, and in this impure state is known as *copperas*, or *green vitriol* (*Ferrum sulphuricum crudum*, P. G.; *Couperose verte, Vitriol vert*, Fr.; *Kupferwasser, Eisenvitriol, Grüner Vitriol*, G.). It usually contains copper, zinc, aluminum, and magnesium sulphates.

Properties.—Ferrous sulphate is in transparent bluish-green monoclinic prisms, or sometimes in rhombic crystals, having the specific gravity 1.9. When crystallized from neutral solutions the salt is pale-green, and in the presence of ferric salt of deeper, more emerald-green color. It is inodorous, has a styptic and somewhat saline taste, a slight acid reaction, melts by heat in its water of crystallization, leaving finally a whitish residue, and when exposed to the air effloresces and is gradually oxidized; the efflorescence takes place more rapidly above 35° C. (95° F.), and when finally heated to 115° C. (239° F.) the loss of water of crystallization amounts to 38.87 per cent. The salt is insoluble in alcohol and ether, but it dissolves at 25° C. (77° F.) in 0.9 and at 100° C. (212° F.) in 0.3 part of water.—U. S. The aqueous solution yields with barium chloride a white precipitate insoluble in hydrochloric acid, a dark-blue one with potassium ferricyanide, and a bluish-white one with potassium ferrocyanide.

Tests.—Impurities are rarely present if the salt has been prepared from iron and sulphuric acid. 1 Gm. of the salt heated to boiling in 25 Cc. of water and 1 Cc. of diluted sulphuric acid, oxidized with nitric acid, and then precipitated with a slight excess of ammonia-water, should give a colorless filtrate, which, after acidifying with hydrochloric acid, should not be colored or made turbid by an equal volume of fresh hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after adding ammonia-water to alkalinity (absence of heavy metals). The filtrate from another portion of the salt, oxidized and precipitated as just described, should not leave a weighable residue on evaporation and ignition (absence of salts of the alkali metals). If 1 Gm. in small fragments be agitated for 5 minutes with 10 Cc. of alcohol, the filtrate should not turn moistened blue litmus-paper red (absence of free acid). If 1.38 Gm. of the uneffloresced salt be dissolved in about 25 Cc. of diluted sulphuric acid, not less than 49.75 Cc. of tenth-normal potassium-permanganate solution should be required to impart to the liquid a permanent pink color (each Cc. of the volumetric solution indicating 2 per cent. of crystallized ferrous sulphate).—U. S.

Each molecule of potassium permanganate is capable of converting 5 molecules of ferrous salt into ferric salt; thus, $10FeSO_4.7H_2O + 2KMnO_4 + 8H_2SO_4 = 5Fe_2(SO_4)_3 + K_2SO_4 + 2MnSO_4 + 78H_2O$; hence each Cc. of tenth-normal permanganate solution used in the above test corresponds to 0.027601 Gm. of ferrous sulphate (crystals), which is equal to 2 per cent. of the weight of the sample used, for 1.3801 : 0.027601 :: 100 : 2. The Br. P. employs a volumetric solution of potassium dichromate, and 1 Gm. of ferrous sulphate should require 36 Cc. (using potassium ferricyanide as indicator), which represents 100 per cent.

Ferri Sulphas Exsiccatus, U. S., Br.; *Ferrum sulfuricum siccum*, P. G.—*Dried (exsiccated) ferrous sulphate or sulphate of iron*, E.; *Sulfate ferreux desséché*, Fr.; *Getrocknetes Ferrosulfat*, G.—Ferrous sulphate, in coarse powder, 100 Gm. Allow the salt to effloresce at a temperature of about 40° C. (104° F.), and then heat it in a porcelain dish, on a water-bath, until the product weighs from 64 to 65 Gm. Lastly, reduce the residue to a fine powder, and transfer it at once to perfectly dry, well-stoppered bottles.—U. S.

The British Pharmacopœia directs the use of a porcelain or iron dish, and the heat to be raised only to 100° C. (212° F.). At a somewhat higher temperature the yield is about 61 per cent. The German Pharmacopœia employs the same method as the U. S.

Crystallized ferrous sulphate contains 45.3 per cent. of water of crystallization, a portion of which is lost in a dry atmosphere at the ordinary temperature, the remainder, except 1 molecule, at 115° C. (239° F.). The last molecule of water is expelled only at about 280° C. (536° F.), and, if proper care be taken, without loss of sulphuric acid.

Exsiccated ferrous sulphate forms a grayish-white powder, which dissolves slowly in cold, more rapidly in hot, water, leaving only a small quantity of ferric oxysulphate. Otherwise, the behavior and tests of purity are the same as for the crystalline salt, nearly 10 parts of which are represented by 6 parts of the exsiccated salt.

Ferri Sulphas Granulatus, U. S.; *Ferri sulphas præcipitatus*, U. S. 1880.—*Precipitated or granulated ferrous sulphate or sulphate of iron*, E.; *Sulfate ferreux précipité*,

Fr.; *Præcipitirtes Ferrosulfat*, G.—Ferrous sulphate, 100 Gm.; distilled water, 100 Cc.; diluted sulphuric acid, 5 Cc.; alcohol, 25 Cc. Dissolve the ferrous sulphate in the distilled water previously heated to boiling, add the diluted sulphuric acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain capsule, on a sand-bath, until it weighs 150 Gm., and then cool it quickly, with constant stirring. Place the product into a glass funnel stopped with a plug of absorbent cotton, and, when it has thoroughly drained, pour upon it the alcohol. When this has also drained, spread the crystallized powder on bibulous paper, dry it quickly, at the ordinary temperature, and transfer it at once to perfectly dry, well-stoppered bottles.—U. S.

Granulated ferrous sulphate may also be prepared by dissolving 8 avoirdupois ounces of the pure salt in 8 fluidounces of boiling distilled water, and adding 2½ fluidrachms of diluted sulphuric acid. After filtration the solution is evaporated to 12 avoirdupois ounces, as directed above, and the granules are washed with 2 fluidounces of alcohol.

The present official directions differ materially from those of 1880, in which the precipitation of the salt was directed with a large volume of alcohol, and also a subsequent washing with alcohol until all free acid was removed. The addition of sulphuric acid (as already stated) is to prevent the oxidation of the ferrous salt, and the washing of the granular product with alcohol removes acid and water, but not entirely. The Br. P. (1898) dropped this preparation.

Action and Uses.—Ferrous sulphate is one of the most astringent salts of iron. When taken in overdose it produces gastric pain, nausea, vomiting, and purging. Because of its astringency it is supposed to be especially adapted to the treatment of leucorrhœa, metrorrhagia, menorrhagia, and other abnormal discharges resulting from anæmia. It has also been employed with advantage in the treatment of gastro-intestinal hemorrhages, gastric ulcer, chronic gastric catarrh, and chronic diarrhœa. Externally a lotion containing from ½ to 2 per cent. of the salt in water has been recommended in chronic conjunctivitis and in leucorrhœa, but is not frequently employed. A 5 per cent. solution in water, or an ointment containing 1 or 2 parts of the salt in 30 parts of lard, may be locally applied in the treatment of erysipelas and eczema. Commercial iron sulphate is largely employed as a disinfectant, but possesses little germicidal power. The dried sulphate of iron is frequently prescribed in pill-form, as the crystallized salt is unfit for that purpose. It should be remembered that 3 grains of the dried ferrous sulphate are practically equivalent to 5 grains of the crystalline salt. The ordinary dose is from 1 to 2 grains (0.06–0.12 Gm.).

FERRUM, *U. S., Br.*—Iron.

Ferrum pulveratum, P. G.—*Mars, Fer*, Fr.; *Eisen*, G.

Symbol, Fe. Atomicity bivalent and apparently trivalent. Atomic weight, 55.5.

Metallic iron, in the form of fine, bright, and non-elastic wire, U. S.; wrought iron in the form of wire or nails free from oxide, Br.; iron in fine powder, P. G.

Origin.—Iron is the most useful and one of the most widely diffused metals in nature, being present in most rocks and soils, and generally forming one of the constituents of the ashes of plants and animals. It is rarely found in the metallic state. It is often combined with sulphur, as *iron pyrites*, more frequently oxidized, as *magnetic iron*, *spathic iron*, *hæmatite*, and other ores, and likewise in combination with mineral acids. It is found in large quantities in several States of North America, and in Great Britain, Sweden, Germany, France, and other European countries.

The manufacture of metallic iron must of necessity vary with the nature of the ore, but the principle is in all cases the same. The ore frequently requires roasting or calcination, mainly for the purpose of rendering it more porous and better adapted for the smelting process; this process is conducted in blast-furnaces, the ore being mixed with carbonaceous matter,—coke and the like,—some flux, either lime or clay, being added at the same time, whereby a more readily fusible silicate of aluminum and calcium compounds present as impurity is formed, which on cooling forms the glass-like slag. The crude iron obtained from the blast-furnace is called *pig* or *cast iron*, and contains various proportions of carbon, silicon, sulphur, phosphorus, and other impurities, from which it must be purified to adapt it for various uses in the arts. In the *refining* or *puddling* process it is fused, and by stirring brought into contact with a blast of air, by which the impurities are oxidized, or the oxidation is effected with the aid of an oxide of iron. The slag still remaining in the iron is then at a white heat pressed out under a steam-hammer,

and the iron thus purified rolled into bars. For many purposes a further purification is requisite.

Properties.—Iron is a grayish metal having the specific gravity 7.7 to 7.9. Its tenacity or strength is nearly twice as great as that of any other metal commonly used, and when heated to redness it possesses a ductility admitting of its being drawn into the thinnest wire. At a white heat it becomes pasty and may be welded, but it can be fused only by the full heat of a blast-furnace, and on congealing it expands somewhat in volume. Iron remains unchanged in dry air, but in the presence of moisture its surface becomes covered with brown-red oxide (*rust*). It enters into combination with nearly all the elements, and forms the base of two important series of salts, the *ferrous* and *ferric*. In the former the valence of iron is two, but in ferric compounds there is at present uncertainty as to the real valence of the iron. It is regarded by some as trivalent, and the formula for ferric chloride, for example, is written $Fe^{III}Cl_3$; others give a double formula to this and similar compounds, thus $Fe^{II}_2Cl_6$, in which it is thought that two iron atoms are united, each exerting a valence of four; thus, $Cl_3Fe—FeCl_3$. A further knowledge of the facts is needed before a final conclusion can be reached. From the close analogy between ferric and aluminum compounds, it seems to be justifiable to consider iron trivalent in the ferric state, as aluminum is considered trivalent in its compounds.

Ferrous salts, when anhydrous, are mostly white, and bluish-green in the hydrated state; the oxalate is yellow. When moist or in solution they are easily oxidized on exposure to the air or under the influence of oxidizing agents. Their aqueous solutions are colored brownish-black by nitric oxide, and yield black precipitates with ammonium sulphide, and white ones, changing to green, black, and brown, with alkalies and their carbonates; the precipitation, particularly with ammonia, is incomplete. Soluble phosphates precipitate white ferrous phosphate, changing to greenish-blue; potassium ferrocyanide produces a bluish-white precipitate, changing to dark-blue, and potassium ferricyanide a dark-blue one. Ferrous solutions free from ferric salt are not affected by potassium sulphocyanate or tannin. The soluble normal ferrous salts have an acid reaction to test-paper; those insoluble in water dissolve in hydrochloric acid.

Ferric salts are either normal or basic; the normal salts, when soluble, having an acid reaction, are mostly white when anhydrous, and brown-yellow when hydrated; the basic salts are of a darker brown or reddish-brown color. Those insoluble in water dissolve in hydrochloric acid. Hydrogen sulphide reduces ferric to ferrous salts, sulphur being separated; ammonium sulphide produces the same reduction, and afterward a black precipitate. Alkali and alkali carbonates added in excess separate brown ferric hydroxide, in the latter case with the evolution of carbon dioxide; the precipitation is prevented by the presence of tartaric acid and some other organic compounds. Alkali acetate, added in the cold, colors the solutions deep brown-red, the color disappearing on the addition of hydrochloric acid; on boiling, a brown precipitate of basic ferric acetate or ferric hydroxide is deposited. Solutions of ferric salts treated with metallic iron, sulphurous acid, or other deoxidizing agents, are reduced to ferrous salts. Sodium phosphate precipitates white ferric phosphate, which is insoluble in acetic acid, becomes brown by ammonia, and if excess of sodium phosphate be present dissolves in ammonia with a red-brown color. Sodium arsenate has a behavior similar to that of the phosphate. Gallotannic acid causes a blue-black color and precipitate (writing-ink). Meconic acid and sulphocyanates color the solutions blood-red, the color produced by the latter reagent being destroyed by corrosive sublimate and by strong mineral acids. Potassium ferricyanide darkens solutions of ferric salts to an olive-brown color; potassium ferrocyanide precipitates Prussian blue.

The official iron powder of the P. G. should contain at least 98 per cent. of iron, by the iodometric method, and should be free from other metals and arsenic, and contain no more than a trace of sulphur, which is tested for as hydrogen sulphide on dissolving the iron in dilute hydrochloric acid, by means of lead acetate paper held in the mouth of the test-tube.

Action and Uses.—Iron in one sense is both a medicine and a food, in that it is useful when the system is in a condition requiring iron to relieve certain pathological states, and also because it is a part of most of the food which is ingested and is utilized daily by the body in the maintenance of health. It is, however, of the greatest importance from a therapeutic point of view to remember that the quantity of iron which is taken in the food each day is exceedingly minute, and that the quantity in the entire

body is very small. For this reason the administration of large doses of iron in the majority of instances is useless and to some extent harmful. The effect of iron when taken in very large doses is to produce constipation, a sense of fulness of the head, and some disorder of the stomach. How largely the head-symptoms are dependent upon the gastric disorder, and how much upon the iron itself, is not fully determined. The drug is absorbed from the stomach and bowels. The bowels also have the ability of excreting it when it is taken into the body in excess.

The exact form in which iron is absorbed has not been determined, but the clinical fact remains that it is a most valuable remedy in the treatment of all forms of anæmia, and particularly in those forms which are characterized by a diminution in the quantity of hæmoglobin rather than by a diminution in the number of the red blood-corpuscles. In other words, it finds its chief field of usefulness in secondary rather than in primary anæmias. As a type of the latter class of anæmia, however, in which iron is valuable is that frequent disorder in young women known as "chlorosis." The usefulness of iron is greatly increased by the employment in moderate quantities of good food, tonics, and mild stimulants, and this is particularly true in the treatment of anæmia following prolonged exhausting diseases, such as typhoid fever and similar infectious maladies. It would also seem probable from clinical experience that the administration of iron is a valuable aid to a patient in combating septic infection, although how it acts under these circumstances is unknown.

All preparations of iron tend to produce constipation if administered in full dose, and for this reason it is often necessary to give laxatives simultaneously. Indeed, in many cases iron seems to be absorbed and utilized much better if administered with a laxative than if administered alone. If given to persons who do not require it, it speedily produces a condition of plethora, and causes a condition which has been known as "iron headache"; that is, pain in the head, and a sensation of fulness, particularly in brow and vertex. For some unknown reason, these disagreeable symptoms are particularly prone to occur in persons who have a gouty or rheumatic tendency. Iron also usually fails to be of much advantage in persons who are suffering from gastro-intestinal catarrh, and from febrile movements non-septic in character. Sometimes in young children the administration of iron produces irritability and catarrh of the bladder, and so results in incontinence of urine. When given in large dose, so much of the iron escapes through the feces as a sulphide that the excrement is colored black, and not infrequently the coating of the tongue is also black, probably due to the formation of a sulphide of iron as a result of decomposition-changes in the saliva. When massive doses of iron are administered, the greater portion of it escapes from the bowels in the feces; a small portion is utilized, and a moderate quantity after absorption is stored in the liver and spleen, where it is used as needed, or ultimately eliminated.

The number of medicinal preparations of iron is exceedingly great. Some of them have therapeutic properties which iron itself does not possess. For the properties of these peculiar preparations of iron, see the preparations already named.

As already pointed out, iron is commonly given in too large quantities. Indeed, in the opinion of the writer, the doses of all the iron preparations, as commonly recommended in works of reference, are too large. Because these doses are accepted as "standard doses," however, they are given in the text dealing with the various preparations of iron, instead of the smaller ones which the writer believes are preferable in most cases.

UNOFFICIAL COMPOUNDS OF IRON.

Ferralbumose.—Finely cut meat freed from fat is digested with artificial gastric juice, the liquid is filtered and freed from albumin by boiling, after which it is exactly neutralized with sodium carbonate, again filtered, and evaporated to dryness in vacuo; 10 Gm. of the dry albumose, dissolved in 90 Cc. of water, are treated with a 10 per cent. solution of ferric chloride until a precipitate ceases to form, after which the precipitate is washed, dried, and sifted. It contains 10 per cent. of iron or 14 per cent. of ferric oxide.

Ferratin.—According to Bunge, iron occurs in foods in a special form very closely combined with albumin. Schmiedeberg extracted this compound from hog's liver and called it ferratin. Böhringer & Sons have patented a process for making artificial ferratin; having the same properties as the natural substance. It is obtained by interaction between egg-albumin, ferric tartrate, and caustic soda. Purified ferratin is a reddish-brown powder, insoluble in plain and weakly acidified water, but soluble in a large proportion of tartaric acid,

and easily soluble in slightly warmed weakly alkaline water. It contains 7–10 per cent. of iron, not in the form of a salt, but apparently united with carbon. It differs from the usual iron albuminates in not turning dark when 1 drop of ammonium sulphide solution is added to a 0.3 per cent. solution in water containing ammonia. Recently a soluble sodium-ferratin has been put on the market. Ferratin is readily absorbed, and causes no digestive disturbances. It is given in chlorosis, acute anæmia, and in cases of great loss of blood, in doses of from 3 to 5 grains (0.20–0.3 Gm.), 3 times a day.

Ferri Albuminas. *Ferrum albuminatum.—Iron albuminate*, E.; *Eisenalbuminat*, G.—35 parts of dry egg-albumin are dissolved in 1000 parts of water at a temperature not above 50° C. (122° F.), and filtered; the solution is then added while stirring to 120 parts of solution of iron oxychloride (P. G.); the resulting turbid, rust-colored solution, which has an acid reaction, is exactly neutralized with 0.75 per cent. sodium hydroxide solution, whereupon the iron albuminate is precipitated (excess of alkali must be avoided, as it dissolves the latter). The precipitate is washed thoroughly by decantation with water at 50° C. (122° F.) until free from chloride (silver nitrate test), filtered, allowed to drain, and pressed to free it from mother-liquor. It is then spread out to dry at a temperature not above 30° C. (86° F.), powdered, and protected against light. Iron albuminate is soluble in dilute alkali, and such a solution is official in the P. G. as *Liquor Ferri Albuminatis.* The powder is ochre-colored, insoluble in water, and contains 13–14 per cent. of iron. A soluble iron albuminate in scales is prepared by the aid of sodium citrate. Used in anæmia and chlorosis. Dose 5 to 20 grains (0.30–1.30 Gm.).

Ferri Benzoas. *Ferrum benzoïcum.—Ferric benzoate*, E.; *Eisenbenzoat, Ferribenzoat*, G. $Fe_2(C_7H_5O_2)_3(OH)_3 + 6H_2O$.—The salt is obtained by interaction between solution of ammonium benzoate and diluted ferric chloride solution. The precipitate is washed thoroughly by decantation, filtered, and dried in the shade at a temperature not above 30° C. (86° F.). It is a brownish-red, odorless, tasteless powder, insoluble in water. It is soluble in hot acids, with deposition of benzoic acid on cooling. Caustic alkalies precipitate ferric hydroxide. Freshly prepared iron benzoate is soluble in codliver oil. It contains 17–18 per cent. of iron or 24.28–25.71 per cent. of ferric oxide.

Ferri Bromidum. *Ferrum bromatum.—Ferrous bromide*, E.; *Eisenbromid, Ferrobromid*, G.; *Bromure ferreux*, Fr. $FeBr_2$.—It is prepared by gradually adding 2 parts of bromine to 1 part of iron filings or wire and 10 parts of water, and digesting until the liquid has a greenish color, when it is filtered and evaporated to dryness in an iron dish. It forms a grayish-black mass, which on exposure to air acquires a brown color through oxidation. From its hot concentrated solution in water it may be obtained in transparent pale-green rhombic plates, of the composition $FeBr_2.6H_2O$. On being heated to redness in contact with the atmosphere, it is converted into ferric oxide and ferric bromide, the latter subliming in yellow scales. Ferrous bromide is used in the form of syrup, which see.

Ferri Caseinas. *Ferrum caseïnatum, Ferrum nucleoalbuminatum.—Iron caseïnate, Iron nucleoalbuminate.*—Diluted skimmed milk is treated with just sufficient strongly diluted acetic acid to precipitate the casein, which is washed repeatedly with warm water, then with alcohol, and finally with ether to remove fat. 1 part of casein is rubbed with 1 part of calcium carbonate and 100 parts of water, and the solution filtered. The calcium caseinate in the filtrate is precipitated with a small excess of a 1 per cent. freshly prepared solution of ferrous lactate. After washing and drying, the precipitated iron caseinate is a flesh-colored, odorless, tasteless powder, insoluble in water, soluble in weak sodium carbonate and ammonia solutions. It contains 2.5 per cent. of iron, and is digested by pancreatin and pepsin and hydrochloric acid. Recommended by Dawydow as an easily absorbable iron compound in place of iron albuminate.

Ferri Ferrocyanidum. *Ferrum cyanatum, Ferrum borussicum.—Ferric ferrocyanide, Prussian blue, Berlin blue*, E.; *Ferrocyanure ferrique, Bleu de Prusse (de Berlin)*, Fr.; *Ferrocyaneisen, Blausaures Eisen, Berliner Blau*, G. $Fe_4[Fe(CN)_6]_3$.—Obtained by adding a solution of 10 parts of potassium ferrocyanide to 20 parts of solution of ferric chloride (1.28 specific gravity) in 200 parts of water. The precipitate is washed with warm dilute hydrochloric acid by decantation, and then thoroughly with water, and dried. It requires considerable washing to free it from the potassium salt, and when dried at a temperature of about 40° C. (104° F.) or lower it retains $18H_2O$ in combination, which it gradually loses at a higher temperature. The double decomposition taking place is expressed thus: $3K_4Fe(CN)_6 + 4FeCl_3 = Fe_4[Fe(CN)_6]_3 + 12KCl$. Ferric ferrocyanide is in dark-blue masses, which exhibit upon the fresh somewhat conchoidal fracture a reddish metallic luster and yield a deep-blue powder. It is inodorous, tasteless, insoluble in water, alcohol, and dilute mineral acids, but dissolves while moist in solution of ammonium nitrate with a violet-blue color, and yields with oxalic acid, equal to one-sixth or more of its own weight, a powder which dissolves completely in water, and which has been used as *wash-blue* and *blue ink;* the residue left on evaporating the solution to dryness has been known as *Bleu suisse* or *Swiss blue.* Commercial Prussian blue should previously be purified for this purpose by treating it with dilute hydrochloric or sulphuric acid and washing with water. Concentrated mineral acids decompose it, with liberation of hydrocyanic acid; when boiled with alkalies, ferric hydroxide is separated and

alkali ferrocyanide dissolved; and when heated in contact with air, ammoniacal vapors are given off and a rust-colored residue is left containing ferric oxide and potassium cyanate, the latter resulting from potassium compounds present in the pigment. Prussian blue is hygroscopic, and contains about 28 per cent. of water. For uses in the arts Prussian blue is made by precipitating ferrous sulphate with potassium ferrocyanide, and exposing the bluish-white precipitate to the air or treating it with oxidizing agents until it has acquired the proper shade; the commoner varieties contain alumina and other impurities. The pigment was accidentally discovered by Diesbach, a manufacturer of colors in Berlin, and a notice of the discovery published in 1710; but processes for preparing it were first published by Woodward, John Brown, and Stephane F. Geoffroy (1724–25); most of the noted chemists of the eighteenth and of the early part of the nineteenth century were engaged in the investigation of its composition and of that of allied compounds. *Soluble Prussian blue* is obtained on adding a solution of a ferric salt (anhydrous ferric chloride, 1 part) to a solution of potassium ferrocyanide (3 parts) (not the reverse), keeping the latter in excess. The deep-blue precipitate will become soluble in water as soon as the greater portion of the foreign salts has been washed out; the precipitate is *potassium ferri-ferrocyanide*, $K_2Fe_2'''[Fe''(CN)_6]_2$. A similar soluble precipitate is obtained by adding a ferrous salt to a solution of red prussiate of potassium (potassium ferricyanide), but it has the composition $K_2Fe_2''[Fe(CN)_6]_2$, and is *potassium ferro-ferricyanide*. *Turnbull's blue, ferrous ferricyanide*, was discovered by Gmelin (1827), and is obtained by adding potassium ferricyanide to a solution of ferrous salt. Ferric ferrocyanidum has no chalybeate effect upon the human economy and is not used in internal medicine.

Ferri Glycerophosphas. *Ferrum glycerinophosphoricum.—Iron glycerophosphate*, E.; *Glycerinphosphorsaures Eisen*, G. $Fe_2[C_3H_5(OH)_2PO_4]_3$.—This salt is obtained by dissolving freshly precipitated ferric hydroxide in glycerophosphoric acid, evaporating the solution in a vacuum apparatus to syrupy consistence, and then spreading on plates of glass and drying at a gentle heat. It forms yellow scales, soluble in water and diluted alcohol. This salt is employed for the same purposes and in the same doses as calcium glycerophosphate (which see).

Ferri Iodidum. *Ferrum iodatum.—Ferrous iodide, Iodide of iron*, E.; *Iodure de fer*, Fr.; *Eisenjodür*, G. FeI_2.—It may be made by mixing 6 Gm. of bright iron wire with 17 Gm. of iodine and 20 Cc. of distilled water in a flask and shaking the mixture occasionally until the solution has acquired a green color and lost the smell of iodine. The solution is then filtered and evaporated rapidly in a dish of polished iron until a drop of the solution on the end of an iron wire solidifies on cooling. The liquid should now be poured into a porcelain dish, and as soon as it has solidified should be broken into fragments and kept in a well-stoppered bottle. The solution of ferrous iodide, on evaporation, is readily oxidized; hence the direction to evaporate in a polished iron dish, which, however, cannot prevent the formation of oxide, or possibly oxyiodide, of iron. The residuary salt is therefore never completely soluble in water. According to de Luca, pure anhydrous ferrous iodide is white, and in the presence of moisture greenish. By the above process, however, it is usually obtained as a steel-gray laminated mass, with a metallic luster, fusing at about 177° C. (350° F.) and evolving vapors of iodine. It is deliquescent when pure, and dissolves readily with a green color in water, also in glycerin and alcohol. Solid ferrous iodide is at best a very unsatisfactory medicinal preparation, owing to the unavoidable changes occurring under ordinary circumstances. Saccharated ferrous iodide was formerly recognized in the U. S. and German pharmacopœias. It is made by mixing a solution of 20.75 Gm. of freshly prepared ferrous iodide, made as stated above, with 40 Gm. of powdered milk-sugar and evaporating on a water-bath, with frequent stirring, until a dry mass remains, which is then transferred to a heated iron mortar, reduced to powder, and intimately mixed with 1 Gm. of reduced iron and sufficient powdered milk-sugar to make the final product weigh 100 Gm. The finished product is a yellowish or grayish-white powder, very hygroscopic, odorless, with a sweetish ferruginous taste and slight acid reaction, and is soluble in 7 parts of water at 15° C. (59° F.). It is given in doses of from 3 to 5 grains (0.20–0.30 Gm.). (See Syrupus Ferri Iodidi.)

Ferri Malas. *Ferrous malate*, E.—Impure malate of iron is recognized by several European pharmacopœias as *extractum ferri pomatum*, which is prepared by digesting the expressed juice of sour apples with 3 or 4 per cent. of iron filings until the reaction has ceased, filtering, and evaporating. It has a blackish-green color, and contains a variable quantity of iron, sometimes as much as 8 per cent. 1 part of it dissolved in 9 parts of cinnamon water, containing one-tenth its weight of alcohol, is known as *Tinctura Ferri Pomata*, P. G. (See also Tinctura Ferri Pomata, N. F.).

Ferri Oxalas. *Ferrum oxalicum oxydulatum.—Ferrous oxalate*, E.; *Ferrooxalat*, G. $FeC_2O_4.2H_2O$.—This is obtained by interaction between solutions of ammonium oxalate and ferrous sulphate as a pale-yellow to lemon-yellow, odorless, nearly tasteless, stable powder, which is difficultly soluble in cold or hot water, soluble and decomposed in hot acids. Used technically as a photographic developer and for preparing iron reduced by hydrogen.

Ferri Oxidum Magneticum. *Ferrum oxydatum magneticum.—Ferroso-ferric oxide, Black oxide of iron, Magnetic oxide of iron*, E.; *Oxyde ferroso-ferrique, Oxyde de fer noir (magnétique), Ethiops martial*, Fr.; *Magneteisen, Ferroferrioxyd, Eisenoxyd-Oxydul*, G. $Fe_3O_4 = FeO.Fe_2O_3$.

—Magnetic oxide, which is found in Sweden and Michigan as magnetic iron ore, consists of 1 molecule each of ferrous and ferric oxide. It is black or brownish-black, and is one of the best ores for manufacturing iron, Swedish iron being of superior quality. It was formerly official in the Br. P. (1867), and was prepared by adding solution of sodium hydroxide to a mixture of ferrous and ferric sulphate in proper proportion, filtering, washing, and drying at 49° C. (120° F.). Under the name of *Æthiops martialis* various pharmacopœias formerly recognized black ferroso-ferric oxide, which varied in composition according to the different methods of preparation.

Ferri Oxidum Rubrum. *Crocus martis adstringens, Colcothar, Caput mortuum.—Ferric oxide*, E.; *Colcothar, Safran de mars astringent*, Fr.; *Eisenoxyd, Rother Eisensafran, Englisch-Roth, Todtenkopf*, G. Fe_2O_3.—It is obtained by heating to redness ferric hydroxide or by igniting ferrous sulphate in contact with air, when the salt is decomposed, water and sulphuric and sulphurous acids being given off. It is brown-red, more or less gritty, inodorous, tasteless, and insoluble in diluted acids. It is no longer employed medicinally, the ferric hydroxide being used instead, but it is used extensively in the arts. It forms the main constituent of iron paint, which is sold as *English red, Berlin red* (*Minium de fer*, Fr.; *Eisenmennige*, G.), and under various other names, and usually consists of ferric oxide mixed with from 5 to 50 per cent. of alumina or other insoluble compound. When obtained as a fine powder by elutriation, it is known as *polishing rouge, terre douce de vitriol, rouge anglais, Polirroth*, and is employed for polishing metals. The mineral *hæmatite* or *red hæmatite, ferret d' Espagne, sanguine, Blutstein*, is ferric oxide, while the various *brown hæmatites* are different ferric hydroxides.

Ferri Peptonas. *Ferrum peptonatum.—Iron peptonate*, E.; *Eisenpeptonat*, G.; *Peptonate de fer*, Fr.—A mixture of 24 parts of solution of dialyzed iron (oxychloride of iron, P. G.) and 200 parts of water is added, in a thin stream and while constantly stirring, to a solution of 2 parts of dry peptone in 200 parts of water; 1.5 per cent. solution of caustic soda is added till a very weak alkaline reaction is produced, whereupon the iron peptonate is precipitated, which is washed as quickly as possible with water by decantation until silver nitrate shows the absence of chlorine; it is then drained on a wet cloth, and dissolved in 3 parts of 25 per cent. hydrochloric acid. The solution is then evaporated on a water-bath, and finally spread on plates to dry at 50°–60° C. (122°–140° F.). Iron peptonate forms shining, brown, translucent scales, containing 24–25 per cent. of iron. It is slowly soluble in cold, more quickly in warm water, the solution having a slight acid reaction, and not being clouded by boiling nor by addition of alcohol. A liquor and a syrup of iron peptonate are also employed. Iron peptonate and its solutions are recommended as superior to the inorganic salts of iron in the treatment of chlorosis and other chlorotic anæmias. The points of superiority consist in their decrease in astringency and in the absence of corrosive effect upon the teeth and mucous membranes. The dose is from 3 to 10 grains (0.20–0.60 Gm.).

Ferri Salicylas. *Ferrum salicylicum.—Ferric salicylate*, E.; *Ferrisalicylat*, G.—Obtained by mixing concentrated solutions of ferric chloride and sodium salicylate, as a brown powder, soon turning to violet, which, after washing and drying, forms an amorphous brown mass or a black-brown powder. It is occasionally given in doses of from 3 to 10 grains (0.2–0.6 Gm.), in pills, as a tonic, antiseptic, astringent, and antirheumatic.

Ferri Subcarbonas, U. S. 1870. *Crocus martis aperitivus* (*aperiens*).—*Subcarbonate of iron*, E.; *Safran de mars apéritif*, Fr.; *Eisensafran*, G.—This compound, formerly official, was prepared by mixing solutions of 8 ounces of sodium carbonate and 9 ounces of ferrous sulphate, washing, and drying without heat. At first a white precipitate of ferrous carbonate is obtained, which in contact with the air rapidly darkens, changing in color through various shades of green, blue, and olive into brown, carbon dioxide being at the same time given off. This change of color is accompanied with its conversion into ferric hydroxide, with the exception of small and variable proportions of ferrous carbonate, which escape oxidation. This preparation must therefore be regarded as identical, or nearly so, with ferric hydroxide. It is an amorphous reddish-brown powder, inodorous and almost tasteless, and closely resembling ferric hydroxide. If it has been dried at an elevated temperature, it is of a brighter red color, does not readily dissolve in warm dilute hydrochloric acid, and consists mainly of the oxyhydrate, $Fe_2O_2.(OH)_2$. Dried at ordinary temperature, it consists chiefly of the oxyhydrate, $Fe_2O_3.Fe_2(OH)_6$. It may be employed for the same purposes as the saccharated ferrous carbonate, but it is not considered as efficient as the latter remedy. The dose is 5 grains (0.30 Gm.).

Ferri Sulphidum. *Ferrum sulphuratum.—Ferrous sulphide*, E.; *Ferrosulfid, Schwefeleisen*, G.; *Sulfure de fer*, Fr. FeS.—Iron unites with sulphur in various proportions, some of the compounds, like iron pyrites, FeS_2, being found in nature. The monosulphide, which is employed for generating hydrogen sulphide, is made by mixing 3 parts of iron filings with 2 parts of sublimed sulphur, introducing the mixture in small portions into a crucible heated to bright redness and kept covered after each addition; or a rod of iron is raised nearly to a white heat and then brought into contact with sulphur; ferrous sulphide will at once form and melt, and should be permitted to drop into cold water to solidify. It is in yellowish-black or blackish masses or irregular pieces, which have a metallic luster and are permanent in dry air, but are oxidized when kept in a damp atmosphere. It dissolves readily in dilute

sulphuric or hydrochloric acid, with the evolution of hydrogen sulphide, and without residue when the sulphide is pure. As met with, it sometimes contains an excess of sulphur, but usually has an excess of iron, and the hydrogen sulphide evolved is mixed with hydrogen. The chief use of ferrous sulphide is for the generation of hydrogen sulphide, H_2S, a colorless gas having an odor like that of rotten eggs and a specific gravity of 1.19 (air = 1). Water dissolves 3 volumes of the gas; the solution is not permanent in the air, but is oxidized, water being formed and white sulphur deposited.

Ferri Tannas. *Ferrum tannicum.—Ferric tannate*, E.; *Ferritannat, Gerbsaures Eisenoxyd*, G.; *Tannate ferrique*, Fr.—Ferric tannates, free from gallate and containing but little of ferrous compound, are produced by precipitating cold solutions of ferric salts with tannin; a mixture of ferrous salt and tannin exposed to the air likewise deposits ferric tannate. Wittstein (1874) found these precipitates to contain between 8.4 and 56.25 per cent. of ferric oxide, the nature of the iron salt and the order of mixing the solutions influencing the composition of the precipitate. A compound containing about one-third its weight of ferric oxide is obtained by preparing the hydroxide from 3 fluidounces of solution of ferric sulphate, and triturating the washed and pressed precipitate with 1 troyounce of tannin and sufficient alcohol, after which it is dried on a water-bath. Tannate of iron is a black or bluish-black powder which is decomposed by mineral and the stronger organic acids. When boiled with water the ferric is reduced to ferrous salt.

Ferri Valerianas. *Ferrum valerianicum.—Ferric valerianate, Valerianate of iron*, E.; *Eisenvalerianat, Baldriansaures Eisenoxyd*, G.—Valerianate of iron is a basic salt of variable composition. It is obtained by adding to a cold solution of ferric sulphate a cold solution of sodium valerianate as long as a precipitate is produced, collecting this upon a filter, washing with a little water, and drying it at a temperature not exceeding 20° C. (68° F.). Prolonged washing and an elevated temperature will produce a more basic salt. It is a dark brick-red light amorphous powder, having a slight odor and a taste of valerianic acid, and is insoluble in cold water, but readily soluble in alcohol. The U. S. P. of 1890 required that the salt upon ignition should leave a residue of 21.42–28.57 per cent. of ferric oxide, representing 15 to 20 per cent. of metallic iron. In the doses of from 1 to 3 grains (0.05–0.20 Gm.) it has been recommended in chlorosis with hysterical attacks.

FERRUM REDUCTUM, *U. S., P. G.*—Reduced Iron.

Ferrum redactum, Br.; *Ferrum hydrogenio reductum, Ferrum ope hydrogenii paratum.—Iron reduced by hydrogen, Iron by hydrogen*, E.; *Fer réduit par l'hydrogène*, Fr.; *Reducirtes Eisen*, G.

It should contain not less than 90 per cent. of pure metallic iron.—U. S., P. G.

Preparation.—Ferric hydroxide is prepared as directed under FERRI HYDROXIDUM, and dried. It is then introduced into an iron tube and heated to dull redness in a current of hydrogen gas, which is purified of acid vapors and other products by passing it through a solution of potassium permanganate, basic lead acetate, and sulphuric acid. After hydrogen ceases to be absorbed, the reduced iron is allowed to cool in the hydrogen to prevent reoxidation, and is then preserved in dry-stoppered bottles. The reaction is $Fe_2O_3 + 6H = Fe_2 + 3H_2O$.

If the temperature is too high, the reduced iron will be more or less granular, instead of being in a finely divided state. 2 pounds of ferric hydroxide require from 5 to 8 hours for complete reduction. The metallic iron reduced by electricity from ferrous sulphate (Böttger), or from ferrous chloride (Collas), has no advantage over that prepared by means of hydrogen.

Properties.—Reduced iron is a very fine gray (grayish-black, U. S., Br.) powder, free from metallic luster, but exhibiting metallic streaks when rubbed with firm pressure in a mortar, and yielding a lustrous scale when struck on an anvil with a hammer. It is without odor or taste, and is not altered in dry air, but is gradually oxidized and becomes rust-colored in a damp atmosphere, and when touched with a lighted taper ignites and is converted into black ferroso-ferric oxide. It is strongly attracted by a magnet, and is insoluble in all simple solvents, but is easily dissolved by dilute hydrochloric or sulphuric acid, with the evolution of hydrogen, the solution showing the reactions of ferrous salts. Reduced iron of a very dark or black appearance should be looked on with suspicion, as it contains a large quantity of oxide which has escaped reduction, or carbon.

Tests.—On treating reduced iron with diluted hydrochloric acid, the undissolved residue should not weigh more then 1 per cent. (carbon).—U. S. The hydrogen should be free from noxious odor, and should not impart a black color to filter-paper moistened with solution of lead acetate and stretched over the orifice of the test-tube; the black color would be due to the presence of sulphur, resulting from the sulphate which remains

in incompletely washed ferric hydroxide. If 1 Gm. of reduced iron be shaken with 5 Cc. of water, the liquid should not change the color of litmus-paper. To 0.5 Gm. of reduced iron in a small covered beaker add 20 Cc. of diluted sulphuric acid; after a while warm on a water-bath until action ceases, then collect any residue of impure iron arsenide upon a very small filter, add the rinsings of the beaker to the filter, and wash the residue with water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, add about 0.25 Gm. of potassium chlorate and 5 Cc. of hydrochloric acid, and evaporate slowly to dryness on a water-bath. Dissolve the residue in water to 50 Cc., then add 5 Cc. of this solution to 5 Cc. of a saturated solution of sulphurous acid and heat on a water-bath for 15 minutes, until all traces of sulphurous acid have been removed. The resulting solution should not respond to the modified Gutzeit's test for arsenic (given under ARSENI TRIOXIDUM). Introduce 0.555 Gm. of reduced iron into a glass-stoppered flask of about 100 Cc. capacity, add 6 Cc. of water, 2 Gm. of potassium iodide, and 2.6 Gm. of iodine, accurately weighed in a weighing-bottle. Securely stopper the 100 Cc. flask, thoroughly rotate the contents, and let stand for 1 hour. Dilute the contents with water to 100 Cc., mix well, and to 25 Cc. of this solution add tenth-normal sodium-thiosulphate solution until the last trace of brown color has disappeared. Divide the weight of iodine taken by 0.02518, and subtract from the quotient twice the number of Cc. of tenth-normal sodium thiosulphate solution used; the remainder represents the percentage of metallic iron present in the reduced iron, and this should not be less than 90 per cent.—U. S.

Note.—The percentage purity of the iodine used should be accurately determined by a previous experiment, and in place of 2.6 Gm., as directed, its equivalent in pure (100 per cent.) iodine taken.—U. S. The P. G. gives the same method of assay. In the above assay only free metallic iron is acted on by the iodine, thus $Fe + I_2 = FeI_2$. The potassium iodide acts as a solvent for the iodine, thus bringing the latter in intimate contact with the iron. From the reaction 55.5 Gm. of Fe require $2 \times 125.9 =$ 251.8 Gm. of iodine, or 0.555 Gm. of Fe taken in the determination require 2.518 Gm. of iodine, if the iron is perfectly pure. Each Cc. of tenth-normal sodium thiosulphate solution is equivalent to 0.01259 Gm. of iodine. If nCc. of thiosulphate solution is required to titrate the excess of iodine in the 25 Cc. portion of the iron solution, the actual amount of iodine entering into combination with the 0.555 Gm. of reduced iron taken would be $(2.6 - 4n \times 0.01259)$ Gm. The weight of pure metallic iron equivalent to this is $\frac{0.555}{2.518} \times (2.6 - 4n \times 0.01259)$ Gm., which is present in 0.555 Gm. taken for assay. Hence the percentage of purity is $\frac{0.555}{2.518} \times (2.6 - 4n \times 0.01259) \times \frac{100}{0.555}$. This expression, when simplified, becomes $\frac{2.6}{0.02518} - 2n$, which is the rule in the Pharmacopœia for finding the percentage. Or, since 215.8 Gm. of iodine are capable of combining with 55.5 Gm. of pure metallic iron, 0.02518 Gm. of iodine will correspond to 1 per cent. of pure iron in the 0.555 Gm. used for the assay, and the quotient obtained by dividing 2.6 by 0.02518 will express the percentage of pure iron corresponding to the 2.6 Gm. of iodine taken. If all the iodine taken could combine with the 0.555 Gm. of reduced iron there would be no necessity for further calculation, but as an unknown excess of iodine is intentionally used, the exact amount in combination must be determined. 1 Cc. of tenth-normal sodium thiosulphate solution corresponding to 0.01259 Gm. of iodine also corresponds to ½ per cent. of pure iron in the 0.555 Gm. used. As only one-quarter of the excess of iodine is titrated in the 25 Cc. of solution, the total excess of iodine is equivalent to 4 times the number of Cc. of tenth-normal sodium thiosulphate solution used, and hence the percentage of pure metallic iron corresponding to such total excess of iodine must be represented by 4 times the number of Cc. of thiosulphate solution multiplied by ¼, or, in other words, by the number of Cc. multiplied by 2. This product subtracted from the quotient obtained above leaves the actual percentage of pure iron present.

The Br. P. requires at least 75 per cent. of metallic iron, which is determined by adding 0.25 Gm. of reduced iron to a hot solution of 1 Gm. of copper sulphate in 15 Cc. of water, closing the flask immediately and shaking occasionally. After 10 minutes the liquid is rapidly filtered out of contact with air as much as possible, acidified with sulphuric acid, and titrated with volumetric potassium dichromate solution, of which 33.7 Cc. should be used before a blue precipitate ceases to form with potassium ferricyanide

(each Cc. of the volumetric solution represents 0.0056 Gm. of iron). The action of the iron on the copper sulphate is $Fe + CuSO_4 = FeSO_4 + Cu$, ferrous sulphate and copper being formed.

Action and Uses.—The medicinal properties and uses of the reduced iron are discussed under FERRUM (which see).

FERRUM PULVERATUM S. ALCOHOLISATUM S. PORPHYRISATUM, or *Pulverized iron*, may be mistaken for reduced iron. It is made in Europe on a large scale from a good quality of cast iron, and therefore contains carbon. It has the general properties of reduced iron, from which it differs in being denser, in having a distinct metallic luster, and in not igniting when touched with a lighted taper; the hydrogen evolved by it has a distinct odor, but should contain only traces of hydrogen sulphide. A solution of the iron in hydrochloric acid should not yield a dark color nor precipitate with hydrogen sulphide (absence of lead, copper, etc.), and when oxidized with nitric acid and treated with ammonia in excess the filtrate should be colorless (copper, etc.), and should not be rendered turbid by ammonium sulphide.

FICUS, *U. S., Br.*—Fig.

Caricæ, Ficus passa, Fici, Fructus caricæ.—*Feige*, G.; *Figue*, Fr.; *Higo*, Sp.

The partially dried fruit of *Ficus Carica* L. (Fam. *Moraceæ*).

Origin and Preparation.—A small soft-wooded tree, or in less favorable climates a shrub, native of southwestern Asia and cultivated in all warm-temperate or subtropical regions. The inflorescence consists of a short, enlarged, hollow axillary branch, which is lined by innumerable minute flowers. The staminate flowers are few and near the mouth. In fruit this hollow branch becomes fleshy and each of the pistillate flowers develops a small yellowish akene, commonly called the seed. The unripe fig is green and contains a milky acrid juice; but on ripening, this juice becomes saccharine and the fruit assumes a yellowish to purple color. In Italy, the early figs, which appear in the axils of the previous year's leaf-scars, are known as *grossi* or *orni*, while those produced in the axils of leaves are known as *forniti* or *cratiri*, the latter name being given to those which ripen after the fall of the leaves. The ripe figs are dried either in the sun or by artificial heat. They then have a wrinkled or shrivelled appearance and a stiff consistency, and thus packed are classed as *natural figs*. When rendered pliant by kneading and squeezing before being packed, they are called *pulled figs*.

FIG. 181.

Ficus Carica L.: *a*, section of fig; *b*, staminate flower; *c*, pistillate flower.

Description.—Irregularly short pear-shaped, about 7.5 Cm. (3 In.) long, and having an average diameter about two-thirds as great; brown or yellowish, or more or less whitened by superficial effloresced sugar; either much shrivelled or wrinkled, or with flat and even surfaces due to pressure of packing, and of a stiff or pliant texture; internally fleshy, mucilaginous, usually translucent, and containing numerous imbedded yellow, seed-like akenes; odor peculiar, fruity; taste sweet, mucilaginous, and pleasant.

Smyrna figs are large and puffy; *Greek figs* are smaller and more wrinkled.

Constituents.—Besides 15 per cent. of akenes and cellular tissue, the fruit yields 50–60 per cent. of glucose, with gum, fat, phosphates, chlorides, etc., but nothing of any special medicinal activity.

Action and Uses.—Figs have long been employed for their nutritive value, but if eaten in large quantities are apt to occasion flatulent colic and diarrhœa. In medicine they are occasionally eaten for their laxative effect in the treatment of habitual constipation. The laxative property resides in the saccharine juice of the fresh fruit, and in the dried fruit is probably due to the indigestible seeds and skin. Applied externally, roasted figs are employed as emollient poultices over gum-boils and small abscesses; and demulcent decoctions are prepared from them and employed in the treatment of catarrhal affections of the nose and throat.

FILICES.—The Ferns.

Except for decorative purposes, this very large group of flowerless plants has few important uses. Under ASPIDIUM, the anthelmintic property of a number of species has been described. This is the most important medicinal property of the group, and most of the species possessing it are at the same time poisonous, very much like Aspidium. It has been claimed that horses and cattle have been poisoned by eating the herbage of *Pteridium aquilinum* (L.) Kuhn (*Pteris a.* L.), the common *Brake* or *Bracken*, but this appears scarcely probable. Gardeners, in handling the herbage of *Davallia Mooreana* Hook. et A., frequently suffer from a cutaneous irritation somewhat resembling that caused by nettles. The poisonous agent in this case has not been determined. Although quite a large number of species are used in native or domestic practice as expectorants, diuretics, carminatives, and astringents, very few of them have been employed in scientific medicine.

Adiantum, Venus-hair or Maiden-hair, Herba capillorum veneris.—Capillaire, Fr. Cod.; *Frauenhaar, Venushaar*, G.; *Capelvenere*, It.; *Culantrillo*, Sp.—This is the frond of *A. capillus-veneris* L. or of *A. pedatum* L. (Fam. *Polypodiaceæ*). These are slender and delicate herbs, growing from slender horizontal rhizomes, the first-named widely distributed through warm-temperate and tropical regions, the second throughout most of eastern and central North America. Venus-hair is about 30 Cm. (1 Ft.) high, the cylindrical stipe blackish-brown and shining, the frond bipinnate to tripinnate below, the pinnules short-stalked, unequal, roundish wedge-shaped with oblique base, obtusely lobed, with linear marginal sori. Maiden-hair is similar, but rather larger, the stem forked at the summit, each branch slightly recurved and divided into 6 or 7 horizontal pinnate branches, the whole leafy portion somewhat horseshoe-shaped, the pinnules triangular-oblong, the inferior margin entire, the superior margin cleft and spore-bearing. The odor is faint; the taste sweetish, slightly bitter and faintly astringent. The constituents are a little tannin, an unknown bitter principle, a trace of volatile oil, with sugar, gum, etc. Adiantum is somewhat aromatic, demulcent, and stimulant. It has been used in the treatment of chronic affections of the respiratory tract, and is said to be of value for the relief of cough. It is employed in the form either of a syrup or an infusion. The so-called *Black maiden-hair* of Europe is *Asplenium Adiantum nigrum* L., and the *White maiden-hair* is *A. rutamuraria* L. *A. trigonum* Labill. is said by Maiden to be used in Tasmania as an astringent and mild emetic.

Scolopendrium Scolopendrium (L.) Karst. (*Asplenium S.* L.; *Phyllitis S.* Greene; *S. vulgare* J. E. Sm.; *S. officinarum* Swz.; *S. officinale* DC.) is *Folia Scolopendrii, F. Phyllitidis* or *F. Linguæ Cervinæ, Hart's-, Lamb's-, Adder's-*, or *Fox-tongue, Snake-, Caterpillar-*, or *Finger-fern; Hirschzunge*, G. The leaves of this peculiar fern, widely distributed through the north-temperate zone, though rare in North America, were formerly much used as a sedative expectorant, mild astringent and alterative, and contain gum, tannin, and a little volatile oil.

Cibotium, Penghawar Djambi, Paleæ or *Pili Cibotii; Farnhaar* (G.), is the chaffy hairs from the bases of the stipes of *Cibotium Djambianum* Hassk., *C. Barometz* J. Sm., and *C. glaucescens* Kunze (Fam. *Polypodiaceæ*), tree-ferns of the East Indies. They are employed generally among the natives as an application to open wounds to check hemorrhage, and this use has prevailed to some extent in scientific surgery. The article is applied either in the entire condition or after being reduced to powder. Different opinions as to whether the mode of action is identical with that of lint have been expressed. It has been assumed that coagulation is chiefly due to absorption of the blood-serum by the dry fiber, but the action seems more energetic than would be thus explained. The hairy rhizomes of these plants, growing in peculiar forms, constituted the *Agnus Scythicus* or *Tartarian Lamb* of ancient fable. *Pulu* is a similar, but finer product yielded by *C. Menziesii* Hook. and *C. glaucum* Hook. et A., of the Sandwich Islands. The similar, but thicker and stiffer material obtained from the base of *Alsophila lurida* Hook., and allied species of Java, is similarly employed under the name *Paku-kidang* or *Pakoe-kidang*. All the above products are employed to a considerable extent as a substitute for hair in stuffing mattresses and other furniture. In Mexico, a similar product, similarly employed under the name *Ocopetate* or *Cola de Mono*, is obtained from *Cibotium Schiedei* Schlecht. (or *Cyathea Mexicana* Ch. et Sch.?).

In South America, a gummy exudation is obtained by wounding the stems of several tree-ferns, and is applied as a protective covering to wounds. Upon drying, it adheres very tightly, resists the action of water, and is highly elastic, like collodion.

In the East Indies and Polynesia the rhizomes of a number of ferns are eaten as starchy foods, or the starch is extracted from them. Cumarin has been reported as occurring in several ferns, and a number have contributed dyestuffs. Although the idea of employing the wood of ferns must appear strange to most persons, yet Maiden reports that beautiful walking-sticks, rustic furniture, and lattice-work are made from the trunk-wood of several arborescent species of *Alsophila*.

FLUIDEXTRACTA.—Fluidextracts.

The term fluidextract, in its present acceptation, is applied to concentrated alcoholic or hydro-alcoholic solutions of vegetable principles, which are permanent and represent all the active virtues of the drugs from which they are made; they are officially recognized in the pharmacopœias of the United States, Great Britain, Germany, and Switzerland, differing but slightly in strength in the four countries.

Fluidextracts, or liquid extracts, as they are called in Great Britain, were first introduced about 1832. Prior to 1847 little interest appears to have been taken in this class of preparations in the United States, only 3 fluidextracts being on record as in use at that time—namely, those of senna, valerian, and rhubarb; from that time forward fluidextracts grew in favor, and the Pharmacopœia of 1850 gave working formulas for 7 concentrated solutions, of which, however, only 1 (valerian) is deserving of the title of fluidextract in the present definition of that term; 2 were oleoresins (cubebs and black pepper), and 4 concentrated syrups (rhubarb, sarsaparilla, senna, and spigelia and senna). In 1860 the number of fluidextracts officially recognized was increased to 25, in 1870 to 46, in 1880 to 79, in 1890 to 88, and in the present (1900) edition of the Pharmacopœia 85 are directed. Besides these a large number of unofficial fluidextracts are annually produced, and this class of preparations must be considered as the most important galenicals used by physicians.

Prior to 1880 the strength of fluidextracts, as prescribed by the Pharmacopœia, was 1 grain of drug to 1 minim of fluidextract; since that time the pharmacopœial strength is based upon the relation of the metric measures of weight and capacity, so that any weight of a given drug is to be converted into a fluidextract having the bulk of the same weight of water at its maximum density, or, in other words, 1 Gm. of the drug is represented by 1 Cc. of the fluidextract. The exceptions to this rule are the fluidextracts of aconite, belladonna root, cinchona, coca, colchicum seed, conium, hydrastis, hyoscyamus, guarana, ipecac, nux vomica, pilocarpus, scopola, and stramonium, all of which are directed to be standardized to definite alkaloidal strength. The present strength of official fluidextracts is about 5 per cent. weaker than formerly. British liquid extracts, with the exception of those of belladonna, cinchona, ipecac, licorice, nux vomica, male fern, opium, and pareira, are of the strength of 1 avoirdupois ounce to 1 Imperial fluidounce, which practically corresponds to our own. In Germany each Gm. of drug is represented by 1 Gm. of fluidextract, the relation being weight for weight.

All the official fluidextracts are directed to be prepared by percolation, a menstruum uniform in alcoholic strength being employed during the process of exhaustion. When, however, glycerin is used with the first portion of the menstruum, percolation is continued and finished with a liquid of the same alcoholic strength, but not mixed with glycerin. By evaporating the weak percolate to a soft extract, most of the water is also expelled, and the comparatively small portion remaining with the extract will occasion but a slight change in the menstruum of the reserved portion, which, at the same time, is the best solvent for the extractive matter; finally, the addition of fresh menstruum will not change the alcoholic strength of the liquid.

It is important that the exhaustion of the drug be conducted as carefully as possible, so that the reserved portion may represent a solution of nearly the whole active virtues of the drug; with this end in view, the rate of percolation for 1000 Gm. of drug should be adjusted to about 5 (not over 8) drops per minute, at which rate about 20 Cc. can be collected in an hour. In the hands of a careful operator, handling such quantities as are given in the pharmacopœial formulas, the official process yields very satisfactory results, and the danger arising from evaporation of the weak percolate may well be disregarded, since from 85 to 90 per cent. of the active principles are most likely contained in the reserved portion, therefore only a small proportion of the medicinal virtues of the drug will be subjected to heat.

The official directions for the preparation of fluidextracts are intended for the quantity of drug designated in the formulas, and must of necessity often be modified by manufacturers who operate upon hundreds of pounds at one time; fineness of powder, degree of packing, and rate of percolation must be adapted to the quantity of material in hand. Manufacturers in some cases resort to repeated maceration and expression instead of percolation.

Authority is given by the Pharmacopœia to employ, where it may be applicable, the

process of repercolation without change of initial menstruum. This process is followed by several manufacturers, and does away with all possibility of injury from application of heat. E. R. Squibb, who was the author of the process, defined it to be "the successive application of the same percolating menstruum to fresh portions of the substance to be percolated." His suggestion was based upon the observation that a weak solution of the constituents of a drug is a better solvent for the soluble active principles of that drug than fresh menstruum. The following example will serve to illustrate the process of repercolation: 1000 Gm. of a properly powdered drug are divided into 5 portions of 200 Gm. each; one portion is moistened, packed, macerated, and percolated to exhaustion, the first 150 Cc. of the percolate being set aside as finished product, the remainder being collected in fractions of 200 Cc., and numbered respectively 1, 2, 3, etc., in the order in which they are collected. The second portion of the drug is moistened with No. 1 weak percolate, packed and percolated to exhaustion, the different weak percolates being used in the order in which they have been collected, followed by fresh menstruum if necessary, the first 200 Cc. of the percolate from this second portion of the drug being set aside as finished product, the remainder being again collected in fractions of 200 Cc., and numbered 1, 2, 3, etc., as before. The third, fourth, and fifth portions of the drug are treated exactly like the second portion, the first 200 Cc. of the percolate in each instance being set aside as finished product. When the fifth portion of the drug has been exhausted there will be on hand five lots of finished product (150, 200, 200, 200, and 200 Cc.; total, 950 Cc.), and, besides, four or five lots of weak percolate supposed to hold in solution the soluble matter from 50 Gm.; these weak percolates, properly numbered, are set aside, to be again used in place of fresh menstruum for the next lot of the same preparation, the process henceforth being continued exactly as directed above for the second portion of the drug. This retention of 25 per cent. of the soluble matter of one portion of the drug in the weak percolates is based on numerous carefully conducted experiments, the results of which showed that when 100 Gm. of drug are exhausted by percolation, from 70 to 80 per cent. of the total soluble constituents present are contained in the first 75 Cc. of percolate. By some the process of repercolation is termed fractional percolation, and modifications of Squibb's method, stated above, have been suggested; in every instance, however, the same principle is kept in view, namely, the use of weak percolates instead of fresh menstruum.

The following directions are given in the National Formulary for application of the process of fractional percolation in the manufacture of fluidextracts: Take of the drug, in powder of the prescribed fineness, 1000 Gm., and divide it into 3 portions, of 500, 325, and 175 Gm., respectively. Moisten the first portion of the drug (500 Gm.) with the menstruum and percolate in the usual manner. Set aside the first 175 Cc. of percolate, and continue until 1500 Cc. more of percolate have passed, which must be received in several portions, so that the more concentrated will be separate from the last, weak percolate. Then moisten the second portion of the drug (325 Gm.) with the more concentrated percolates received during the preceding operation after the first 175 Cc. have passed, and percolate again in the usual manner, using the several reserved percolates, successively, as menstrua. Set aside the first 325 Cc., and continue the percolation until 650 Cc. more have passed, which should also be received in several portions. Finally, moisten the third portion of the drug (175 Gm.) with the most concentrated of the last reserved percolates, and proceed as directed for the second portion. Collect 500 Cc. of percolate, and mix with the two portions (325 and 175 Cc.) previously set aside, so as to make 1000 Cc. of fluidextract.

It stands to reason that when either repercolation or fractional percolation is employed in the manufacture of fluidextracts, the menstruum must remain uniform throughout, not only in regard to the proportion of alcohol present, but also as to the amount of glycerin or other addition made to the original liquid.

Since it is intended in the above process of fractional percolation to represent in 1000 Cc. of finished product the active constituents of 1000 Gm. of drug, the question arises whether this is always possible. Some drugs are more easily exhausted than others, and in our experience complete exhaustion of the drug has at times not been effected with the collection of the last 500 Cc. of percolate. This defect does not occur with repercolation, since only 950 Cc. of finished fluidextract are made from 1000 Gm. of drug, the remaining 50 Gm. being represented in the several lots of weak percolate set aside for another occasion.

All fluidextracts, no matter how carefully made, will begin to deposit soon after they are completed, and this precipitation will continue for a varying length of time. The menstruum dissolves certain extractive principles which it is incapable of retaining in perfect solution afterward under changes of temperature, and thus far no method is known to prevent entirely such separation, which is augmented by exposure to light, air, and heat. Fluidextracts prepared without heat are less prone to deposit than when made by the official process, and in these the amount of precipitate is often very trifling; happily, frequent examinations of precipitates in fluidextracts have disclosed the facts that they consist chiefly of inert extractive matter, and therefore do not affect the medicinal value of the preparation. All freshly made fluidextracts should be set aside in well-stoppered glass vessels, in dark and moderately cool places, for a period of 2 or 3 months, before filtering and bottling them; this plan is universally followed by large manufacturers, and explains the absence, in many cases, of appreciable deposits.

With few exceptions the fluidextracts of the Pharmacopœia are prepared by the following general formula: the quantity of menstruum for moistening the drug, the degree of pressure to be used in packing, and the quantity of percolate to be set aside as reserve being specified in each case:

1000 Gm. of the powdered drug of the prescribed degree of fineness are thoroughly moistened with a certain quantity of the initial menstruum and packed more or less firmly in a cylindrical percolator; the drug, having been properly covered with a paper diaphragm, enough menstruum is poured on to saturate completely the powder and leave a stratum above it. When liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator to prevent evaporation, macerate for 48 hours. Then allow percolation to proceed slowly, gradually adding menstruum (alcohol or alcohol and water), until the drug is exhausted. Reserve the first 700 to 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion and add sufficient menstruum to make the fluidextract measure 1000 Cc.

Concentration of the weak percolate is usually effected by distilling off the alcohol in a suitable apparatus on a water-bath, and finally evaporating the liquid, in a porcelain capsule, to the proper consistence, preferably with constant stirring. The Pharmacopœia does not in every case specify the temperature for evaporation, but it is best to keep it always below 50° C. (122° F.), so as to avoid changes in the extractive, as far as possible.

Of the 85 official fluidextracts, 10 are made with alcohol alone.

Arranged according to the menstruum, the official fluidextracts may be divided into 22 classes, as follows:

Alcohol: aromatic powder, capsicum, cimicifuga, cubeb, gelsemium, ginger, Indian cannabis, lupulin, savin, veratrum.

Alcohol 4 volumes, water 1 volume: belladonna root, eriodictyon, euonymus, mezereum, podophyllum, rhubarb, scopola, serpentaria, stavesacre.

Alcohol 3 volumes, water 1 volume: aconite, buchu, calamus, eucalyptus, grindelia, ipecac, leptandra, matico, nux vomica (with acetic acid), sumbul, valerian, xanthoxylum.

Alcohol 7 volumes, water 3 volumes: calumba.

Alcohol 2 volumes, water 1 volume: bitter orange-peel, colchicum seed, hyoscyamus, stramonium, viburnum opulus, viburnum prunifolium.

Alcohol 6½ volumes, water 3½ volumes: convallaria.

Alcohol 1 volume, water 1 volume (diluted alcohol): berberis, chimaphila, chirata, coca, conium (with acetic acid), cypripedium, digitalis, ergot (with acetic acid), eupatorium, gentian, guarana, krameria, lappa, phytolacca, pilocarpus, quillaja, rubus, scutellaria, senna, spigelia, stillingia, taraxacum.

Alcohol 5 volumes, water 8 volumes: frangula.

Alcohol 4 volumes, water 6 volumes: rhamnus purshiana.

Alcohol 1 volume, water 2 volumes: quassia, sarsaparilla.

Alcohol 8 volumes, glycerin 1 volume, water 1 volume, followed by a mixture of alcohol 8 volumes, water 2 volumes: cinchona.

Alcohol 6 volumes, water 3 volumes, glycerin 1 volume, followed by a mixture of alcohol 2 volumes, water 1 volume: hydrastis.

Alcohol 6 volumes, water 3 volumes, glycerin 1 volume, followed by a mixture of alcohol 6 volumes, water 4 volumes: apocynum, geranium, pareira.

Diluted alcohol 9 volumes, glycerin 1 volume, followed by diluted alcohol: granatum, quercus, rhus glabra, rose, sarsaparilla (compound fluidextract).

Alcohol 3 volumes, water 6 volumes, glycerin 1 volume, followed by a mixture of alcohol 1 volume, water 2 volumes: hamamelis.

Alcohol 2 volumes, water 5 volumes, glycerin 3 volumes: uva ursi.

Alcohol 2 volumes, water 6 volumes, glycerin 2 volumes: wild cherry.

Alcohol 6 volumes, water 3 volumes, solution of potassium hydroxide 0.3 volume: senega.

Alcohol 1 volume, glycerin 1 volume, water 2 volumes, followed by diluted alcohol: aromatic rhamnus purshiana.

Diluted acetic acid, 10 per cent. solution: lobelia, sanguinaria, squill.

Boiling water: glycyrrhiza, triticum. Finished product contains about 25 per cent. by volume of alcohol as a preservative, and in the case of glycyrrhiza also 25 per cent. of glycerin and 5 per cent. of ammonia-water.

The following fluidextracts were dropped in the revision of the 1890 Pharmacopœia: arnica root, asclepias, aspidosperma, castanea, colchicum root, cusso, dulcamara, gossypium, iris, menispermum, rumex, scoparius, stramonium seed.

The following fluidextracts have been introduced for the first time in the 1900 Pharmacopœia: berberis, euonymus, granatum, quercus, quillaja, rhamnus purshiana (aromatic), scopola, stavesacre, sumbul, stramonium leaves.

FLUIDEXTRACTUM ACONITI, *U. S.*—Fluidextract of Aconite.

Fluidextractum aconiti radicis.—Fluidextract of aconite root, E.; *Extrait liquide de racine d'aconit*, F.; *Flüssiges Akonitknollenextrakt*, G.

Preparation.—Aconite, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical glass percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the aconite is exhausted. Reserve the first 900 Cc. of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of aconitine in the remainder of the liquid, add to this enough menstruum to make each 100 Cc. of the finished fluidextract contain 0.4 Gm. of aconitine.

Assay of Fluidextract of Aconite.—Fluidextract of aconite, 10 Cc.; ether, distilled water, ammonia-water, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin test-solution, of each a sufficient quantity. Pour 10 Cc. of fluidextract of aconite into an evaporation-dish and evaporate carefully to dryness on a water-bath at a temperature not exceeding 60° C. (140° F.). Add 5 Cc. of tenth-normal sulphuric acid and 10 Cc. of distilled water. When the extract is dissolved, filter into a separator, washing the dish and filter with about 40 Cc. of distilled water. To the contents of the separator add 25 Cc. of ether and 2 Cc. of ammonia-water, and agitate for a minute. Draw off the lower layer into a flask and filter the ether into a beaker. Return the aqueous fluid to the separator, add 15 Cc. of ether, and agitate a minute. Again draw off the lower layer into the flask and filter the ether into the beaker. Repeat the process with 2 other portions of 10 Cc. each of ether. Evaporate the ether to dryness and dissolve the residue in 3 Cc. of tenth-normal sulphuric acid. Add to the solution 5 drops of hematoxylin test-solution, and then carefully run in fiftieth-normal potassium hydroxide solution until a violet color is produced, the transition stages being as follows: first yellow, then green, finally passing into violet. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 3 (the 3 Cc. of tenth-normal sulphuric acid used), multiply the remainder by 0.064, and this product by 10 (or multiply at once by 0.64), which will give the weight in grammes of aconitine in 100 Cc. of the fluidextract of aconite.—U. S.

25 avoirdupois ounces of aconite should be moistened with about 10 fluidounces of the menstruum (alcohol 3 volumes, water 1 volume), and the first 22 fluidounces of the percolate set aside as reserve.

When assaying preparations of aconite, it is important to avoid a rise of temperature above that directed, as aconitine is easily decomposed. It will also be found advantageous to add 5 Gm. of powdered pumice stone to the fluidextract before evaporation, as this will facilitate subsequent extraction of the resinous residue and filtration of the liquid.

The correct end-reaction in the assay of aconite, when hematoxylin is used as indicator, is green, the color of transition from yellow to violet, but the first appearance of violet will also answer.

EXTRACT OF ACONITE has very properly been dropped from all the pharmacopœias. The solid extract is not a very satisfactory preparation, since the alkaloid present in the percolate of the root is apt to undergo decomposition during the prolonged exposure to heat required for evaporation to a pilular substance, and the extract is often found to have an acid reaction.

If small quantities of extract of aconite are wanted, they may be readily obtained by evaporating a convenient amount of the fluidextract in a porcelain capsule on a water-bath, at a temperature not exceeding 50° C. (122° F.), to a pilular consistence.

Uses.—The action of this preparation is identical with that of ACONITUM (which see). It is frequently employed as an ingredient to liniments for the purpose of relieving superficial neuralgias, but is rarely employed in internal medicine. The internal dose is from ½ to 1 minim (0.025–0.05 Cm.).

FLUIDEXTRACTUM APOCYNI, *U. S.*—Fluidextract of Apocynum.

Fluidextract of Canadian hemp, E.; *Extrait liquide de chanvre du Canada*, Fr.; *Flüssiges Canadisch-Hanfwurzelextrakt*, G.

Preparation.—Apocynum, in No. 60 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 600 Cc. of alcohol and 300 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolater; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of 600 Cc. of alcohol to 400 Cc. of water, until the apocynum is exhausted. Reserve the first 900 Cc. of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with 10 fluidounces of the menstruum (alcohol 6 volumes, water 3 volumes, glycerin 1 volume), and the first 22 fluidounces of the percolate set aside as reserve. The final volume of the finished product is made up to 24 fluidounces by addition of a mixture of alcohol 6 volumes and water 4 volumes.

It has been found that a slightly weaker menstruum than that formerly (1890) used, extracts the drug equally well and yields a satisfactory preparation.

Uses.—The employment of this remedy is identical with that of APOCYNUM (which see). Dose, 5 minims (0.30 Gm.). As an emetic it may be given in doses of from 15 to 20 minims (1–1.3 Cc.).

FLUIDEXTRACTUM AROMATICUM, *U. S.*—Aromatic Fluidextract.

Extrait liquide des aromates, Fr.; *Flüssiges Gewürzextrakt*, G.

Preparation.—Aromatic powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of alcohol, and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and,

having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the aromatic powder is exhausted. Reserve the first 850 Cc. of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powder should be moistened with about 9 fluidounces of alcohol, and the first 21 fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

This preparation is of a rich red-brown color, and has the warm aromatic taste of the powder.

Uses.—This preparation is valuable for disguising the odor and taste of many remedies. It may be added in small quantities to powdered drugs in order to produce a more eligible preparation. It is rarely administered alone. The dose is from 10 to 30 minims (0.60–2 Cc.).

FLUIDEXTRACTUM AURANTII AMARI, *U. S.*—Fluidextract of Bitter Orange-peel.

Extrait liquide d'écorce d'orange amère, Fr.; *Flüssiges Pomeranzenschalenextrakt*, G.

Preparation.—Bitter orange-peel, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it moderately in a conical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the orange-peel is exhausted. Reserve the first 800 Cc. of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of the menstruum (alcohol 2 volumes, water 1 volume), and the first 19½ fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

In preparing this fluidextract it should be remembered that the orange-peel should consist almost exclusively of the glandular epidermal layer, known in commerce as Curaçoa orange-peel. Prepared from good material, the preparation will be of a yellowish-brown color and have the agreeable odor and pleasantly bitter taste of the peel.

Uses.—Because of its aromatic properties this remedy is frequently employed with other bitter tonics. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM BELLADONNÆ RADICIS, *U. S.*—Fluidextract of Belladonna Root.

Extractum Belladonnæ Liquidum—Liquid Extract of Belladonna, Br.—*Extrait liquide de racine de belladone*, Fr.; *Flüssiges Tollkirschenwurzelextrakt*, G.

Preparation.—Belladonna root, in No. 60 powder, 1000 Gm.; alcohol, water, a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the belladonna root is exhausted. Reserve the first 800 Cc. of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of alkaloids in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished fluidextract contain 0.5 Gm. of the alkaloids from belladonna root.

Assay of Fluidextract of Belladonna Root.—Fluidextract of belladonna root, 10 Cc.; distilled water, ammonia-water, chloroform, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin or iodeosin test-solution, each a sufficient quantity. Measure 10 Cc. of fluidextract of belladonna root into a separator, add 10 Cc. of distilled water, 20 Cc. of chloroform, and 2 Cc. of ammonia-water. Shake well for several minutes, and draw off the lower chloroformic layer into a second separator. Repeat the extraction twice with 10 Cc. of chloroform, and draw each 10 Cc. of chloroform into the second separator. To the latter add 5 Cc. of normal sulphuric acid and 20 Cc. of distilled water, shaking well for several minutes. Draw off and reject the lower chloroformic layer, and filter the acid aqueous layer into a clean separator. Wash the last separator and filter with 10 Cc. of distilled water, adding this to the aqueous fluid in the separator. To the latter add 10 Cc. of chloroform and 4 Cc. of ammonia-water, and shake well for several minutes. Draw off the lower chloroformic layer into a beaker, and repeat the extraction twice with 10 Cc. of chloroform, adding the chloroform to the beaker. Allow the chloroform in the beaker to evaporate on a moderately warm water-bath until the residue is perfectly dry. Add 5 Cc. of tenth-normal sulphuric acid to the beaker, and when the residual alkaloids have all dissolved, titrate the solution with fiftieth-normal potassium hydroxide solution, using 5 drops of hematoxylin or iodeosin test-solution as indicator. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.0287, and this product by 10 (or multiply at once by 0.287), to obtain the weight in grammes of alkaloids contained in 100 Cc. of the fluidextract of belladonna root.—U. S.

25 avoirdupois ounces of the powdered root should be moistened with about 9 fluidounces of the menstruum (alcohol 4 volumes, water 1 volume), and the first 20 fluidounces of the percolate set aside as reserve.

Liquid extract of belladonna of the Br. P. is made by repercolation, as follows: 8 ounces of the root in No. 20 powder are moistened with 6 fluidounces of a menstruum composed of 90 per cent. alcohol 7 volumes and water 1 volume, and set aside for 6 hours; the powder is then packed firmly in a percolator and 6 fluidounces more of the menstruum added; when the liquid begins to drop, the lower orifice of the percolator is closed and maceration continued for 24 hours, after which percolation is allowed to go on slowly, using more menstruum as required and collecting the percolate in small portions. A second quantity of powdered root is moistened with the first 6 fluidounces of percolate collected, and then treated exactly as in the case of the first lot of drug, using as menstruum, however, the liquid collected in portions as percolate from the first 8 ounces. Two more portions of 8 ounces of powdered root are then treated exactly as the second portion, the third portion being extracted with the liquid from the second percolator, and the fourth portion with the liquid from the third percolator. From the fourth portion of drug 12 fluidounces of strong percolate are finally collected, in which the proportion of alkaloids present is determined, and sufficient of the alcohol and water mixture given above added to produce a liquid extract containing 0.75 Gm. of total alkaloids in 100 Cc. or $\frac{3}{4}$ grain in 110 minims. The alkaloids in the strong percolate are determined by the following method:

Introduce 10 Cc. of the liquid into a separator, add 10 Cc. of chloroform, 50 Cc. of water, and a decided excess of ammonia-water; set aside; draw off the chloroformic layer. Twice repeat the agitation with chloroform and the separation. Shake the combined chloroformic solutions with 5 Cc. of diluted sulphuric acid, mixed with twice its volume of warm water; separate the chloroformic fluid and repeat the agitation with acidulated water. The mixed acid liquids are washed with 3 Cc. of chloroform, and then agitated with 10 Cc. of chloroform and an excess of ammonia-water. Separate the chloroformic solution and twice repeat the agitation with chloroform and the separation; wash the mixed chloroformic solutions with 5 Cc. of water containing 1 drop of ammonia-water; draw off the chloroformic layer into a tared dish and evaporate on a water-bath; finally dry the residue below 100° C. (212° F.) and weigh. Dissolve the residue in 10 Cc. of tenth-normal hydrochloric acid and add hundredth-normal sodium hydroxide solution until the liquid is neutral, using tincture of cochineal as indicator. Deduct the volume of sodium hydroxide solution thus required from 100 Cc., and multiply the remainder by 0.00287; the product will represent the weight of total alkaloids contained in the 10 Cc. of strong percolate used for the assay.

Since a fluidextract of belladonna leaves is occasionally employed, the above preparation should always be designated by the title of the U. S. P., given above. Care should be taken in the selection of belladonna root, which should not be woody. This fluidextract has a reddish-brown color.

The alcoholic strength of the menstruum is sufficient to exhaust the drug perfectly and yield a stable preparation, hence the addition of water is fully justified.

Uses.—This preparation is equally as efficient as the drug from which it is prepared. The dose is from 1 to 2 minims (0.05–0.10 Cc.).

FLUIDEXTRACTUM BERBERIDIS, *U. S.*—Fluidextract of Berberis.

Fluidextract of barberry, E.; *Extrait liquide de bérberide (d'épine-vinette)*, Fr.; *Flüssiges Berberitzenextrakt*, G.

Preparation.—Berberis, in No. 60 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol and pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol until the berberis is exhausted. Reserve the first 700 Cc. of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of the menstruum, and the first 18 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Uses.—The properties of this preparation are fully described under BERBERIS (which see). Dose, 2 to 5 minims (0.10–0.3 Cc.).

FLUIDEXTRACTUM BUCHU, *U. S.*—Fluidextract of Buchu.

Extrait liquide de bucco, Fr.; *Flüssiges Buccoextrakt*, G.

Preparation.—Buchu, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol and 250 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the buchu is exhausted. Reserve the first 850 Cc. of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of the menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The menstruum of fluidextract of buchu has again been changed to a mixture of alcohol and water, as it was in 1880, since this has been found to exhaust the drug equally well and the finished product keeps well. When made with the present menstruum, the fluidextract has about the same physical properties as that of the 1890 Pharmacopœia, as regards color, odor, and taste.

Uses.—This preparation exhibits the entire activity of buchu, but unless it is largely diluted with water is inferior to the infusion in the treatment of renal diseases. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM CALAMI, *U. S.*—Fluidextract of Calamus.

Extrait liquide d'acore vrai, Fr.; *Flüssiges Kalmusextrakt*, G.

Preparation.—Calamus, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 350 Cc. of the menstruum, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the calamus is exhausted.

Reserve the first 900 Cc. of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of powdered calamus should be moistened with about 9 fluidounces of a mixture of alcohol 3 volumes, water 1 volume, and the first 22 fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Made from peeled calamus, this fluidextract is of a brownish-yellow color, but if prepared from the unpeeled rhizome, which is directed to be used, it is of a considerably darker tint, the characteristic odor and taste being likewise more prominent. The reduction in alcoholic strength of the menstruum (the U. S. P. 1890 directed strong alcohol) is justified by experience, as it has been found that calamus can be completely exhausted by the present mixture of alcohol and water, the finished product keeping well. For preparing the powder the air-dry calamus should be dried over unslaked lime, but not by heat, which would expel much of the volatile oil. In view of the large intercellular passages contained in the tissue of calamus a powder passing through a No. 40 or even No. 30 sieve would seem to be sufficiently fine for ready extraction.

Extractum Calami, P. G.—*Extract of calamus*, E.; *Extrait d'acore vrai*, Fr.; *Kalmusextrakt*, G.—The German Pharmacopœia directs extract of calamus to be made by exhausting finely cut calamus with a mixture of alcohol 2 parts and water 3 parts by maceration, filtering the expressed liquid, and evaporating to the consistence of a thick extract. Extract of calamus is of a reddish-brown color, has the peculiar aromatic odor of the drug, and forms a turbid solution when mixed with water.

Uses.—The fluidextract may be used in all the cases for which calamus is appropriate. It is a convenient form of that drug. Dose, from 5 to 20 minims (0.3–1.3 Cc.).

FLUIDEXTRACTUM CALUMBÆ, *U. S.*—Fluidextract of Calumba.

Extrait liquide de colombo, Fr.; *Flüssiges Kolomboextrakt*, G.

Preparation.—Calumba, in No. 20 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 700 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the calumba is exhausted. Reserve the first 700 Cc. of the percolate; by means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of the menstruum (alcohol 7 volumes, water 3 volumes) and the first 17½ fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The fluidextract is of a rich orange-brown color, and possesses a strongly bitter taste.

Solid extract of calumba is sometimes prescribed. It can be readily prepared by evaporating the fluidextract to a pilular consistence, in a porcelain capsule, on a water-bath.

Uses.—This preparation represents the bitter properties of the drug. Being one of the few which contains no tannic acid, it may be readily employed in conjunction with the various preparations of iron. The dose is from 10 minims to 1 fluidrachm (0.6–4 Cc.).

FLUIDEXTRACTUM CANNABIS INDICÆ, *U. S.*—Fluidextract of Indian Cannabis.

Extrait liquide de chanvre indien, Fr.; *Flüssiges Indisch-Hanfextrakt*, G.

Preparation.—Indian cannabis, in No. 30 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the Indian cannabis is exhausted. Reserve the first 900 Cc. of the percolate; by means of a water-bath distil off the alcohol from the remainder and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of alcohol, and the first 22 fluidounces of percolate set aside as reserve.

There is scarcely any necessity for this preparation, since the extract of Indian cannabis is readily soluble in alcohol. The fluidextract is of a dark-green color. If properly prepared it may be used for the extemporaneous preparation of the extract.

Uses.—This preparation is of variable strength and should always be physiologically tested before being used. When good it represents the virtues of the drug. The beginning dose is from ½ to 1 minim (0.025–0.05 Cc.), which amount may be gradually increased if necessary.

FLUIDEXTRACTUM CAPSICI, *U. S.*—Fluidextract of Capsicum.

Fluidextract of red pepper, E.; *Extrait liquide de capsique, de piment des jardins*, Fr.; *Flüssiges Spanisch-Pfefferextrakt*, G.

Preparation.—Capsicum, in No. 50 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 500 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the capsicum is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of capsicum should be moistened with 12 fluidounces of alcohol, and the first 22 fluidounces of percolate set aside as reserve.

There is likewise little need for this preparation, the drug being already represented by the oleoresin and the tincture. The fluidextract is of a rich brown-red color, yields a turbid mixture with water, and has the burning taste of the drug.

Uses.—The dose is from 1 to 2 minims (0.05–0.10 Cc.).

FLUIDEXTRACTUM CHIMAPHILÆ, *U. S.*—Fluidextract of Chimaphila.

Fluidextract of pipsissewa, E.; *Extrait liquide de pyrole ombellée*, Fr.; *Flüssiges Doldenmangoldextrakt*, G.

Preparation.—Chimaphila, in No. 30 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol and pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the chimaphila is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of the menstruum, and the first 20 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Experience has shown that the addition of about 10 per cent. of glycerin improves the stability of the fluidextract; the same result might be obtained by using a mixture of alcohol 2 volumes and water 1 volume.

Uses.—The employment of this preparation is described under CHIMAPHILA. The fluidextract is thought by some to be less efficient than an infusion. The dose is from 30 to 60 minims (2–4 Cc.) several times daily.

FLUIDEXTRACTUM CHIRATÆ, *U. S.*—Fluidextract of Chirata.

Extrait liquide de chirette, Fr.; *Flüssiges Chirettaextrakt*, G.

Preparation.—Chirata, in No. 30 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the chirata is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of diluted alcohol, and the first 21 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The fluidextract is reddish brown, and has the intensely bitter taste of the drug. The bitter principles of chirata being soluble in water, the present weaker menstruum is indicated for this drug. Although precipitation takes place after some time, the active principles are probably not affected thereby.

Uses.—Dose, 15 to 30 minims (1–2 Cc.).

FLUIDEXTRACTUM CIMICIFUGÆ, *U. S.*—Fluidextract of Cimicifuga.

Extractum Cimicifugæ Liquidum—Liquid Extract of Cimicifuga, Liquid Extract of Actæa racemosa, Br.—*Fluidextract of black cohosh*, E.; *Extrait liquide à grappes*, Fr.; *Flüssiges Cimicifugaextrakt*, G.

Preparation.—Cimicifuga, in No. 60 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 250 Cc. of alcohol, and pack it in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cimicifuga is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of cimicifuga should be moistened with 6 fluidounces of alcohol, and the first 22 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

This has all the sensible properties of the drug from which it was made, and is a permanent preparation. That of the Br. P. is nearly identical with the foregoing, the menstruum being 90 per cent. alcohol.

Uses.—This is probably the best preparation of cimicifuga to employ, as it possesses all of the virtues of the drug. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM CINCHONÆ, *U. S.*—Fluidextract of Cinchona.

Extractum Cinchonæ Liquidum—Liquid Extract of Cinchona, Br.; *Extractum chinæ calisayæ fluidum.—Extrait liquide de quinquina jaune*, Fr.; *Flüssiges Chinaextrakt, Kalisayarindenextrakt*, G.

Preparation.—Cinchona, in No. 60 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 800 Cc. of alcohol and 100 Cc. of water. Moisten the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When

the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, and when the liquid in the percolator has disappeared from the surface gradually pour on a mixture of alcohol and water, made in the proportion of 800 Cc. of alcohol to 200 Cc. of water, and continue the percolation until the cinchona is exhausted. Reserve the first 700 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain, by calculation, the amount of anhydrous ether-soluble alkaloids in the remainder of the liquid, and add to this sufficient of a mixture of alcohol and water, using the same proportions as before, to make each 100 Cc. of the fluidextract contain 4 Gm. of anhydrous ether-soluble alkaloids from cinchona.

Assay of Fluidextract of Cinchona.—Fluidextract of cinchona, 10 Cc.; normal sulphuric acid, ammonia-water, chloroform, ether having a specific gravity not above 0.720 at 25° C. (77° F.), each a sufficient quantity. Place 10 Cc. of fluidextract of cinchona into a flask or bottle and pour over it a mixture of 100 Cc. of ether, 25 Cc. of chloroform, and 10 Cc. of ammonia-water. Cork securely and shake vigorously for 10 minutes. Decant or pipette off 66 Cc., representing 5 Cc. of the fluidextract, into a measuring cylinder, and transfer to a separator, washing the cylinder out with 5 Cc. of ether, and adding this to the separator. Add to the latter about 10 Cc. of normal sulphuric acid, or sufficient to make the solution distinctly acid, and shake vigorously for several minutes. Draw off the lower layer into a second separator. To separator No. 1 add 5 Cc. more of normal sulphuric acid and 5 Cc. of distilled water, shake for several minutes, and when the liquids have separated draw off the lower layer into separator No. 2. Now add 5 Cc. of distilled water to separator No. 1, shake as before, and also draw off the lower aqueous layer into separator No. 2. To the contents of separator No. 2 add 25 Cc. of ether and a small piece of red litmus-paper. Then add, gradually, ammonia-water, keeping the temperature of the liquids below 25° C. (77° F.), until the reaction is alkaline. Then shake vigorously for 1 or 2 minutes, and let liquids separate for 10 minutes, at a temperature below 15° C. Draw off and discard the lower aqueous layer, and then transfer the ethereal layer into a tared beaker. Add 5 Cc. more of ether to the separator, rinse carefully, and add the rinsings to the tared beaker, and entirely evaporate the ether at a moderate heat on a water-bath. Then dry the beaker in an air-bath at 120° C. (248° F.) for 2 hours, and weigh, allowing to cool, preferably in a desiccator. Replace in the air-bath, and heat again for half an hour, cool, and weigh, repeating until the weight is constant. The weight of alkaloids so obtained multiplied by 20 gives the number of grammes of anhydrous ether-soluble alkaloids in 100 Cc. of the fluidextract.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of menstruum (alcohol 8 volumes, glycerin 1 volume, water 1 volume), and the first 20 fluidounces of percolate set aside as reserve; when 24 fluidounces of menstruum have been used, percolation is to be continued with a mixture of alcohol 8 volumes and water 2 volumes.

The Br. P. gives the following directions:

Macerate for 2 days red cinchona, in No. 60 powder, 20 ounces with water 100 ounces, glycerin 2½ fluidounces, and hydrochloric acid 5 fluidrachms; percolate, exhaust with water, evaporate below 82.2° C. (180° F.) to 20 fluidounces. After determining the alkaloidal strength of the liquid, every volume of it containing 5 Gm. of total alkaloids is first brought to 85 Cc. either by evaporation, or, if necessary, by dilution with distilled water; then a volume of 12.5 Cc. of 90 per cent. alcohol is to be added, and the final adjustment of the volume to 100 Cc. is to be made by addition of distilled water. The finished liquid extract will thus contain 5 Gm. of the total alkaloids of cinchona bark in every 100 Cc.

The assay of the liquid extract is directed to be carried out as follows: 5 Cc. of the liquid are put into a separator, together with 25 Cc. of water; 30 Cc. of benzolated amyl alcohol and 15 Cc. of solution of potassium hydroxide are then added, and the mixture thoroughly and repeatedly shaken; after complete separation of the liquids, draw off the alkaline aqueous fluid into another separator. To the contents of the second separator add 30 Cc. of benzolated amyl alcohol and agitate thoroughly; allow to separate; draw off and reject the lower layer, and add the alcoholic fluid to the contents of the first separator. Wash with a little water; add 30 Cc. of a warm mixture of 1 volume of diluted hydrochloric acid and 5 volumes of water, and agitate thoroughly; allow to separate; draw off the lower acid layer into a clean separator; agitate the alcoholic layer with a second quantity of 30 Cc.

of the mixture of acid and water; when separated, draw this off and add to the other acid liquid. To the mixture add 10 Cc. of chloroform and sufficient ammonia-water to impart a strongly alkaline reaction; shake thoroughly; allow to separate; draw off the lower chloroformic layer into a tared dish; repeat the agitation and separation with 2 successive portions of 10 Cc. of chloroform, and add the chloroformic liquids to the contents of the dish. Evaporate the chloroform slowly on a water-bath, dry the residue at a temperature of 110° C. (230° F.), and weigh.

The first formula is decidedly the better. Fluidextract of cinchona is of a rich, red-brown color, and if made from good bark contains all the alkaloids in their natural combination. Water alone will but partially exhaust cinchona bark, and during the long-continued evaporation a portion of the alkaloids will become insoluble through alteration of the tannin. On the other hand, a stronger alcohol will dissolve more cinchonic red, but secure the more thorough exhaustion of the alkaloids.

Uses.—This preparation may be employed as a tonic in doses of from ½ to 1 fluidrachm (2–4 Cc.). It is probably superior to any one of the various alkaloids contained in the bark, but because of the large doses which would be required it is rarely used in the treatment of severe malarial fevers.

FLUIDEXTRACTUM COCÆ, *U. S.*—Fluidextract of Coca.

Extractum Cocæ Liquidum—Liquid Extract of Coca, Br.; *Extractum erythroxyli fluidum*, U. S., 1880.—*Fluidextract of erythroxylon*, E.; *Extrait liquide de coca*, Fr.; *Flüssiges Cocaextrakt*, G.

Preparation.—Coca, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 450 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the coca is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of ether-soluble alkaloids in the remainder of the liquid, and add to this sufficient diluted alcohol to make each 100 Cc. of the fluidextract contain 0.5 Gm. of ether-soluble alkaloids from coca.

Assay of Fluidextract of Coca.—Fluidextract of coca, 10 Cc.; ammonia-water, ether, distilled water, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin or iodeosin test-solution, each a sufficient quantity. Measure 10 Cc. of fluidextract of coca into a separator, add 25 Cc. of ether, and then 2 Cc. of ammonia-water, shaking together for several minutes. When the fluids have separated, draw off the lower aqueous layer into a second separator, and to this second separator add 20 Cc. more of ether, and repeat the shaking for a minute. Draw off and reject the lower aqueous layer from the second separator, and add the ethereal layer to the first separator. To this separator now add 5 Cc. of normal sulphuric acid and 5 Cc. of distilled water, shaking well for a minute or two. After the liquids have separated, draw off the lower aqueous layer into a clean separator, and repeat the extraction in the first separator with 9 Cc. of distilled water and 1 Cc. of normal sulphuric acid, shaking for a minute. Add the aqueous solution to the other separator, and reject the ether. Now add to the acid liquid 20 Cc. of ether and sufficient ammonia-water to make it distinctly alkaline, and shake for a minute or two. Draw off the separated aqueous layer into another separator and the ethereal layer into a beaker. Repeat the extraction of the aqueous layer in the other separator with 10 Cc. and again with 10 Cc. of ether, and add the resulting ethereal extracts to the beaker. Now evaporate off the ether from the beaker spontaneously, and when dry add to it 5 Cc. of tenth-normal sulphuric acid, and stir until the alkaloids are all dissolved. Then add 5 drops of hematoxylin or iodeosin test-solution, and titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of Cc. of fiftieth-normal potassium-hydroxide solution used by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.03, and this product by 10 (or multiply at once by 0.3), to obtain the weight in grammes of ether-soluble alkaloids contained in 100 Cc. of the fluidextract of coca.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10¼ fluidounces of menstruum, and the first 19½ fluidounces of percolate set aside as reserve.

The liquid extract of coca of the Br. P. is made in a very similar manner to the above, 60 per cent. alcohol being directed as the menstruum. No requirement for definite alkaloidal content, however, is made.

Fluidextract of coca is of a deep-brown or olive-brown color, has a pleasant tea-like odor, and the bitter astringent and slightly aromatic taste of the leaves.

Uses.—This is an excellent preparation of coca, and is largely employed in doses of from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM COLCHICI SEMINIS, *U. S.*—Fluidextract of Colchicum Seed.

Extrait liquide de semence de colchique, Fr.; *Flüssiges Zeitlosensamenextrakt*, G.

Preparation.—Colchicum seed, in No. 50 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the colchicum seed is exhausted. Reserve the first 750 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of colchicine in the remainder of the liquid, and add to this enough menstruum to make each 100 Cc. of the fluidextract contain 0.5 Gm. of colchicine.

Assay of Fluidextract of Colchicum Seed.—Fluidextract of colchicum seed, 10 Cc.; ether, chloroform, alcohol, ammonia-water, normal sulphuric acid, distilled water, each a sufficient quantity. Measure into a separator 10 Cc. of fluidextract of colchicum seed, add 1 Cc. of ammonia-water, and shake out the alkaloid with 3 successive portions, 15, 15, and 10 Cc. of chloroform. Collect the chloroformic solutions in a beaker or dish, and evaporate it nearly to dryness by applying a very gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether is evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in the beaker or dish. Redissolve the residue in a little ether, add 5 Cc. of water, and proceed as before. Wash the container, and filter with a little water, and shake the aqueous solution well for 1 minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a tared flask, and again shake out the aqueous liquid, successively, with three portions of 10 Cc. each of chloroform, collecting these solutions in the tared flask. Evaporate the chloroferm completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve it in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.) until the weight, after cooling in a desiccator, remains constant. Multiply the weight of the residue by 10 to obtain the weight, in grammes, of colchicine contained in one hundred cubic centimetres of the fluidextract of colchicum seed.—U. S.

25 avoirdupois ounces of the powdered seed should be moistened with about 7½ fluidounces of menstruum (alcohol 2 volumes, water 1 volume), and the first 18 fluidounces of percolate set aside as reserve.

Uses.—The fluidextract of the root is probably more efficient than that prepared from the seed, but they may be used interchangeably. Dose, from 2 to 8 minims (0.10–0.50 Cc.).

FLUIDEXTRACTUM CONDURANGO.—Fluidextract of Condurango.

Extractum Condurango fluidum, P. G.—*Extrait liquide de condurango*, Fr.; *Flüssiges Condurangoextrakt*, G.

Preparation.—Condurango bark, in No. 25 powder, 100 parts; glycerin, $6\frac{2}{3}$ parts; alcohol, water, each a sufficient quantity to make 100 parts. Mix the glycerin with $66\frac{2}{3}$ parts of alcohol and $26\frac{2}{3}$ parts of water, and, having moistened the powder thoroughly with sufficient of the menstruum, set the mixture aside in a closed vessel for 2 or 3 hours. Transfer to a percolator, pack firmly, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 24 hours at a temperature of 15°–20° C. (59°–68° F.). Allow percolation to proceed at the rate of 15–20 drops per minute, pouring on menstruum composed of alcohol 1 part, water 3 parts, until the drug is exhausted. Reserve the first 85 parts; evaporate the remainder of the percolate to a syrupy consistence, and add sufficient menstruum to make 15 parts. Mix the two liquids, and set aside for 2 or 3 days, then filter.—P. G.

Fluidextract of condurango is of brown color and has the specific gravity 1.038–1.040, yielding from 16–20 per cent. of extractive.

It should be borne in mind that all liquid preparations of the German Pharmacopœia are made by weight.

Uses.—This is probably the best preparation of condurango to employ. The dose is from 1 to 2 fluidrachms (4–8 Cc.).

FLUIDEXTRACTUM CONII, *U. S.*—Fluidextract of Conium.

Extractum conii fructus fluidum.—Fluidextract of hemlock fruit, of conium seed, E.; *Extrait liquide de semence (fruit) de ciguë*, Fr.; *Flüssiges Schierlingsfruchtextrakt*, G.

Preparation.—Conium, in No. 40 powder, 1000 Gm.; acetic acid, 20 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the acetic acid with 980 Cc. of diluted alcohol, and, having moistened the powder with 300 Cc. of the menstruum, pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the conium is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of coniine in the remainder of the liquid, and add to this sufficient diluted alcohol to make each 100 Cc. of the fluidextract contain 0.45 Gm. of coniine.

Assay of Fluidextract of Conium.—Fluidextract of conium, 10 Cc.; ether, alcohol, ammonia-water, normal sulphuric acid, sodium carbonate test-solution, hydrochloric acid (5 per cent.), distilled water, of each a sufficient quantity. Transfer 10 Cc. of fluidextract of conium to an evaporating dish containing a little clean sand, and evaporate it to dryness by means of a water-bath. Mix the sand uniformly with the extract and transfer it to an Erlenmeyer flask of about 250 Cc. capacity, rinsing the dish with 100 Cc. of a mixture of ether 320 Cc., alcohol 25 Cc., and ammonia-water 10 Cc., added in portions, and transfer the rinsings to the flask. Insert the stopper securely and shake the flask at intervals during 1 hour. Decant 50 Cc. of the liquid (representing 5 Cc. of the fluidextract) into a beaker, and add sufficient normal sulphuric acid to produce a distinctly acid reaction. Evaporate the ether at a gentle heat by aid of a water-bath; then add 15 Cc. of absolute alcohol, and set the beaker aside in a cool place for 2 hours to allow the ammonium sulphate to deposit. Filter the liquid; wash the residue and filter with a little absolute alcohol, and add the washings to the filtrate; neutralize any excessive amount of acid with sodium carbonate test-solution, being careful to retain a slight acidity. Concentrate the liquid to 3 Cc. by the aid of a gentle heat on a water-bath, add 3 Cc. of distilled water and 2 drops of normal sulphuric acid. Add 15 Cc. of ether to remove traces of fatty matter, pour off the ether solution, and repeat the washing. Then transfer the acid liquid to a separator, introduce a small piece of red litmus-paper, and add sufficient sodium carbonate test-solution to render the liquid slightly alkaline; then shake out with sucessive portions of 15, 10, and 10 Cc. of ether. To the combined ether-solutions

in a tared beaker add, drop by drop, sufficient hydrochloric acid (5 per cent.) to insure an excess of acid, and then evaporate the ether by means of a gentle heat on a water-bath. Remove the excess of hydrochloric acid by adding to the residue 3 Cc. of alcohol and heating gently to evaporate the liquid, repeat this operation once, and dry the residue at a temperature not exceeding 60° C. (140° F.) until the weight remains constant after cooling. Multiply the weight of the residue by 0.777 and then by 20 (or at once by 15.54), to obtain the weight in grammes of coniine contained in 100 Cc. of the fluidextract of conium.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of the menstruum (diluted alcohol 49 volumes acetic acid 1 volume); after 24 fluidounces of menstruum have been used, percolation is to be continued with diluted alcohol, and the first 22 fluidounces of percolate set aside as reserve.

A fluidextract, prepared from the fully developed green fruit of conium, is preferable to that from the leaves. The acetic acid is added for the purpose of preventing evaporation of the readily volatile coniine. The fluidextract keeps well, is of a brown-green color, and has the peculiar odor of conium, which is considerably increased on the addition of potassium hydroxide.

Solid extract of conium may be readily prepared by evaporating a convenient quantity of the fluidextract to a pilular consistence, in a porcelain capsule on a water-bath, at a temperature not exceeding 50° C. (122° F.).

Uses.—The fluidextract is a convenient form and, next to the juice, the most reliable for the administration of conium. Dose, 2 to 5 minims (0.10–0.30 Cc.).

FLUIDEXTRACTUM CONVALLARIÆ, *U. S.*—Fluidextract of Convallaria.

Fluidextract of lily of the valley, E.; *Extrait liquide de muguet*, Fr.; *Flüssiges Maiblumenwurzelextrakt*, G.

Preparation.—Convallaria, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 650 Cc. of alcohol with 350 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the convallaria is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces should be moistened with about 10 fluidounces of the menstruum, and the first 19½ fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Experience has shown that the fluidextract, when made with a somewhat stronger alcoholic menstruum, keeps better than as formerly made with diluted alcohol.

Uses.—This preparation is the one most commonly employed. For its medicinal properties, see CONVALLARIA. The dose is from 3 to 15 minims (0.20–1 Cc.).

FLUIDEXTRACTUM CUBEBÆ, *U. S.*—Fluidextract of Cubeb.

Extrait liquide de cubèbe, Fr.; *Flüssiges Kubebenextrakt*, G.

Preparation.—Cubeb, in No. 40 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 250 Cc. of alcohol, and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cubeb is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of powdered cubeb should be moistened with about 6 fluidounces of the menstruum, and the first 22 fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

This fluidextract should not be confounded with the oleoresin of the same drug,

which was formerly recognized as fluidextract; it contains the medicinally active resin, together with most of the volatile oil, is of a dark-green color, and has the odor and taste of cubeb.

Uses.—This preparation is less efficacious than the powdered drug, but it may be employed when the drug is indicated. The dose is from 15 to 40 minims (1–2.6 Cc.).

FLUIDEXTRACTUM CYPRIPEDII, *U. S.*—Fluidextract of Cypripedium.

Fluidextract of ladies' slipper, E.; *Extrait liquide de cypripède de jaune*, Fr.; *Flüssiges Gelbfrauenschuhextrakt*, G.

Preparation.—Cypripedium, in No. 60 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cypripedium is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of menstruum, and the first 21 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Experience has taught that a mixture of alcohol 2 volumes, water 1 volume, will yield better results than either alcohol or diluted alcohol.

Fluidextract of cypripedium is of a reddish-brown color, with the taste of the drug well marked.

Uses.—Dose, 5 to 15 minims (0.3–1 Cc.).

FLUIDEXTRACTUM DIGITALIS, *U. S.*—Fluidextract of Digitalis.

Extrait liquide de digitale, Fr.; *Flüssiges Digitalisextrakt*, G.

Preparation.—Digitalis, in No. 60 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the digitalis is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of digitalis should be moistened with about 10 fluidounces of diluted alcohol, and the first 21 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The fluidextract is of a green-brown color, and a fair representative of digitalis; the precipitate which is formed on standing probably retains little or none of the active principles of the leaves. Diluted alcohol exhausts the drug thoroughly, the finished preparation keeping as well as when made with the stronger alcoholic menstruum of 1890.

Uses.—The fluidextract has no marked advantages over the tincture, which is commonly employed. The dose is from 1 to 2 minims (0.05–0.10 Cc.).

FLUIDEXTRACTUM ERGOTÆ, *U. S.*—Fluidextract of Ergot.

Extractum ergotæ liquidum—Liquid Extract of Ergot, Br.—*Extractum secalis cornuti fluidum*, P. G.—*Extrait liquide d'ergot de seigle*, Fr.; *Flüssiges Mutterkornextrakt*, G.

Preparation.—Ergot, recently ground and in No. 60 powder, 1000 Gm.; acetic acid, 20 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the acetic acid with 980 Cc. of diluted alcohol, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the mixture to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator,

macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the ergot is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of the menstruum (diluted alcohol 49 volumes, acetic acid 1 volume), and the first 21 fluidounces of percolate set aside as reserve; when 24 fluidounces of the menstruum have been used, percolation is to be continued with diluted alcohol. The final volume of the finished product should be made up to 24 fluidounces.

The corresponding preparation of the Br. P. is equally efficient. The following is the formula: Take of ergot, crushed, 20 ounces; distilled water, 7½ pints (Imperial); alcohol (90 per cent.), 7½ fluidounces. Digest the ergot in 5 pints of the water for 12 hours; draw off the infusion and repeat the digestion with the remainder of the water; press out, strain, and evaporate the liquids by the heat of a water-bath to 14 fluidounces; when cold add the alcohol; allow to stand for an hour, then filter. The product should measure 20 fluidounces.—Br.

The P. G. directs that 100 parts of ergot shall be exhausted with a menstruum composed of 1 part of alcohol and 4 parts of water (both by weight); the first 85 parts of percolate are set aside as reserve and the weak percolate, after addition of 2.4 parts of 25 per cent. hydrochloric acid, is evaporated to a syrup, mixed with sufficient menstruum to make 15 parts, and then added to the reserve tincture.

The large quantity of fixed oil present in ergot is liable to be displaced by percolation with an alcoholic menstruum, but not with water. None of the pharmacopœias direct the removal of the oil; this may be accomplished by exhausting the ergot with ether or petroleum benzin.

Uses.—The uses of fluidextract of ergot are fully described under ERGOTA (which see). It is probably the best preparation of the drug for internal administration. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM ERIODICTYI, *U. S.*—Fluidextract of Eriodictyon.

Fluidextract of yerba santa, E.; *Extrait liquide d'eriodictyon*, Fr.; *Flüssiges Eriodictyonextrakt*, G.

Preparation.—Eriodictyon, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the eriodictyon is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of the menstruum (alcohol 4 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Fluidextract of yerba santa is of a deep brownish-green color, pleasantly aromatic odor, and a slightly astringent not disagreeable taste; the menstruum perfectly exhausts the drug and yields a stable preparation.

Uses.—This preparation is employed chiefly for the purpose of disguising the bitter taste of quinine. It may be given in doses of from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM EUCALYPTI, *U. S.*—Fluidextract of Eucalyptus.

Extrait liquide d'eucalyptus, Fr.; *Flüssiges Eukalyptusextrakt*, G.

Preparation.—Eucalyptus, in No. 40 powder, 1000 Gm.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water,

and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the eucalyptus is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of eucalyptus should be moistened with about 10 fluidounces of the menstruum (alcohol 3 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Uses.—This forms an efficient method for the administration of the drug. The dose is from 5 to 15 minims (0.3–1 Cc.).

FLUIDEXTRACTUM EUONYMI, *U. S.*—Fluidextract of Euonymus.

Fluidextract of wahoo, E.; *Extrait liquide d'écorce de fusain*, Fr.; *Flüssiges Spillbaumrindenextrakt*, G.

Preparation.—Euonymus, in No. 40 powder, 1000 Gm.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of alcohol and water as before, until the euonymus is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with 9 fluidounces of the menstruum (alcohol 4 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of euonymus is one of the newly introduced preparations of the Pharmacopœia. It has a brown color and a bitter taste. Since the active virtues of the drug reside in the resinous constituents, the menstruum must necessarily be strongly alcoholic, although a somewhat weaker alcohol will also exhaust the drug perfectly. The preparation is chiefly intended for the preparation of the powdered extract.

Uses.—Dose, 1 to 2 drachms (4–8 Cc.).

FLUIDEXTRACTUM EUPATORII, *U. S.*—Fluidextract of Eupatorium.

Fluidextract of boneset.—Fluidextract of thoroughwort, E.; *Extrait liquide d'eupatoire perfoliée*, Fr.; *Flüssiges Durchwachsdostenextrakt*, G.

Preparation.—Eupatorium, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the eupatorium is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of diluted alcohol, and the first 19½ fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

This fluidextract is of a dark-greenish or brown-red color, and represents the virtues of the drug.

Uses.—The tonic properties of eupatorium are well represented in 1-fluidrachm (4 Cc.) doses of this preparation.

FLUIDEXTRACTUM FRANGULÆ, *U. S.*—Fluidextract of Frangula.

Extractum frangulæ fluidum, P. G.; *Extrait liquide d'écorce de bourdaine*, Fr.; *Flüssiges Faulbaumrindenextrakt*, G.

Preparation.—Frangula, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 500 Cc. of alcohol with 800 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the frangula is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of menstruum (alcohol 5 volumes, water 8 volumes), and the first 19½ fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The P. G. directs a menstruum of 3 parts of alcohol and 7 parts of water. both by weight.

The fluidextract has a dark brown-red color and sweetish bitter taste.

Uses.—This is an active preparation of the drug. The dose is from 10 to 30 minims (0.6–2 Cc.).

FLUIDEXTRACTUM GELSEMII, *U. S.*—Fluidextract of Gelsemium.

Extrait liquide de gelsemium, Fr.; *Flüssiges Gelsemiumextrakt*, G.

Preparation.—Gelsemium, in No. 60 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of alcohol, and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the gelsemium is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of alcohol, and the first 22 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Alcohol is well adapted for exhausting gelsemium. The fluidextract has a deep red-brown color and the strong odor and bitter taste of the drug.

Uses.—This preparation is rarely employed at the present time. Its uses are fully described under the drug. The dose is from 1 to 3 minims (0.05–0.20 Cc.).

FLUIDEXTRACTUM GENTIANÆ, *U. S.*—Fluidextract of Gentian.

Extrait liquide de gentiane, Fr.; *Flüssiges Enzianextrakt*, G.

Preparation.—Gentian, in No. 30 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the gentian is exhausted. Reserve the first 800 Cc. of the percolate. By means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of gentian should be moistened with about 9 fluidounces of

menstruum, and the first 19½ fluidounces of percolate set aside as a reserve; the final volume of the finished product should be made up to 24 fluidounces. The bitter principle of gentian is perfectly soluble in water, but a certain amount of alcohol is necessary for preventing fermentation.

Uses.—Fluidextract of gentian is employed as a stomachic and simple bitter tonic. The preparation is usually given in conjunction with other remedies having a similar action. The dose is from 10 to 30 minims (0.6–2 Cc.).

FLUIDEXTRACTUM GERANII, *U. S.*—Fluidextract of Geranium.

Extrait liquide de géranium maculé, Fr.; *Flüssiges Fleckstorchschnabelextrakt*, G.

Preparation.—Geranium, in No. 30 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 600 Cc. of alcohol and 300 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water made in the proportion of 6 volumes of alcohol and 4 volumes of water, until the geranium is exhausted. Reserve the first 750 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of the menstruum (alcohol 15 fluidounces, water 7½ fluidounces, glycerin 2½ fluidounces), and the first 17½ fluidounces of percolate set aside as reserve; after the 25 fluidounces of menstruum have been used, percolation is to be continued with a mixture of alcohol 6 volumes and water 4 volumes. The final volume of the finished product is to be made up to 24 fluidounces.

The increase of alcohol in the menstruum for fluidextract of geranium is a decided improvement, and has been found to preserve the finished product better than diluted alcohol, formerly used. The tendency to partial gelatinization has been materially lessened. The fluidextract is of dark reddish-brown color and has a strongly astringent taste.

Uses.—Because of its astringency, fluidextract of geranium may be employed with success in the treatment of serous diarrhœas. The adult dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM GLYCYRRHIZÆ, *U. S.*—Fluidextract of Glycyrrhiza.

Extractum glycyrrhizæ liquidum—Liquid Extract of Liquorice, Br.—*Fluidextract of licorice or liquorice*, E.; *Extrait liquide de réglisse*, Fr.; *Flüssiges Sussholzwurzelextrakt*, G.

Preparation.—Glycyrrhiza, in No. 20 powder, 1000 Gm.; glycerin, 250 Cc.; ammonia-water, 50 Cc.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Pour 400 Cc. of boiling water upon the glycyrrhiza, contained in a suitable vessel, and allow it to stand for 1 hour. Pack the moistened powder loosely in a metallic percolator, pour boiling water upon it, and allow the percolation to proceed, supplying boiling water until the glycyrrhiza is exhausted. Evaporate the percolate at a moderate heat until it measures 450 Cc., and, when cool, add 450 Cc. of alcohol, mix well, and set it aside for 3 days. After filtering the liquid, distil it until 500 Cc. of distillate have been obtained; transfer the liquid in the still to a glass or porcelain vessel, add the glycerin, ammonia-water, and 200 Cc. of alcohol. Finally, add sufficient water to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with 10 fluidounces of boiling water, macerated for 1 hour, and then percolated to exhaustion with boiling water. After evaporation of the percolate to 11¼ fluidounces, an equal volume of alcohol is added, and the mixture set aside for 3 days. The mixture is filtered and distilled until 12½ fluidounces of distillate have been obtained. To the residue, 6 fluidounces of glycerin, 1¼ fluidounces of ammonia-water, and 5 fluidounces of alcohol are added, and, finally, sufficient water to bring the volume of the finished product up to 24 fluidounces.

The Br. P. directs the exhaustion of the licorice root with 2 successive portions of cold water, using each time 50 fluidounces for 20 ounces of the drug, and allowing the mixture to macerate for 24 hours before expressing. The mixed infusions are heated to 100 C. (212 F.), strained through flannel, and evaporated until the liquid has acquired, when cold, a specific gravity of 1.200; ¼ of its volume of alcohol is now added and the mixture is set aside for 12 hours, after which it is filtered.

Fluidextract of licorice has a yellowish-brown color and should have a pure sweet taste free from acridity. It is not at all likely that in the British process the drug will be completely exhausted by treatment twice with cold water and subsequent expression.

Uses.—Fluidextract of licorice is employed almost exclusively as a vehicle for disguising the taste of bitter drugs. It increases the secretion of the salivary glands and acts also as a mild laxative. The dose is from 1 to 2 fluidrachms (4–8 Cc.).

FLUIDEXTRACTUM GRANATI, *U. S.*—Fluidextract of Granatum.

Fluidextract of pomegranate-root bark, E.; *Extrait liquide d'écorce de grenadier, Extrait liquide d'écorce de balaustier*, Fr.; *Flüssiges Granatwurzelrindenextrakt*, G.

Preparation.—Granatum, in No. 30 powder, 1000 Gm.; glycerin, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of diluted alcohol, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the granatum is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with about 10 fluidounces of a mixture of glycerin 2½ fluidounces and diluted alcohol 21½ fluidounces; subsequent percolation is to be continued with diluted alcohol. The first 20 fluidounces of percolate are to be set aside as reserve and the final volume of finished product brought up to 24 fluidounces.

Fluidextract of pomegranate bark is of a greenish-brown color and has a slightly astringent taste, but no decided odor. The menstruum directed is capable of exhausting the drug perfectly and the finished preparation keeps well.

Uses.—The employment of this preparation is fully described under GRANATUM (which see). The dose is from 20 to 30 minims (1.3–2 Cc.).

FLUIDEXTRACTUM GRINDELIÆ, *U. S.*—Fluidextract of Grindelia.

Extrait liquide de grindélia, Fr.; *Flüssiges Grindelienextrakt*, G.

Preparation.—Grindelia, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the grindelia is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of a mixture of 24 volumes of alcohol and 8 volumes of water, and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

This fluidextract is of a brown-green color. The official menstruum has been changed to a somewhat weaker alcohol, as it has been found that the latter exhausts the drug thoroughly, and that the finished product keeps as well as when made with alcohol alone. The active principles are, most likely, volatile oil and resin.

Uses.—This is an efficacious preparation of grindelia. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM GUARANÆ, *U. S.*—Fluidextract of Guarana.

Extrait liquide de guarana, Fr.; *Flüssiges Guaranaextrakt*, G.

Preparation.—Guarana, in No. 60 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 200 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the guarana is exhausted. Reserve the first 700 Cc. of the percolate. By means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 6 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of alkaloids contained in the remainder of the liquid; add to this sufficient diluted alcohol to make each 100 Cc. of the finished fluidextract contain 3.5 Gm. of the alkaloids from guarana.

Assay of Fluidextract of Guarana.—Guarana, 5 Cc.; chloroform, ether, ammonia-water, normal sulphuric acid, distilled water, each a sufficient quantity. Transfer to a separator 5 Cc. of fluidextract of guarana, add 15 Cc. of chloroform and 1 Cc. of ammonia-water. Shake well and allow the liquids to separate completely. Draw off the chloroform into a beaker. Shake out the fluid remaining in the separator with two additional portions of chloroform of 10 Cc. each, evaporate the combined chloroformic solutions carefully to dryness. Dissolve the alkaloidal residue in 20 Cc. of warm distilled water. Allow it to cool, and filter the solution into a separator, rinse the flask and filter with distilled water, adding the rinsings to the separator, then add 10 Cc. of chloroform, and shake the separator for 1 minute. Draw off the chloroform into a tared flask, and repeat the extraction with 10 Cc. of chloroform, adding this to the tared flask. Distil off the chloroform, and, when dry, add 2 Cc. of ether, and evaporate this very carefully with the aid of a water-bath (to avoid decrepitation). Dry the residue to a constant weight on the water-bath. Multiply the weight by 20, which will give the weight in grammes of alkaloids contained in 100 Cc. of fluidextract of guarana.—U. S.

25 avoirdupois ounces of guarana should be moistened with about 5 fluidounces of diluted alcohol, and the first 19½ fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of guarana has been in use for a number of years, but in the endeavor to obtain it as little alcoholic as possible many of the preparations formerly used gradually formed heavy deposits. Experience has shown that the present official menstruum yields very satisfactory results. The fluidextract is of a deep red-brown color and has an astringent and bitter taste.

Uses.—This is probably the best preparation of guarana to employ. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM HAMAMELIDIS FOLIORUM, *U. S.*—Fluidextract of Hamamelis Leaves.

Extractum Hamamelidis Liquidum—Liquid Extract of Hamamelis, Br.—*Fluidextract of witch-hazel leaves*, E.; *Extrait liquide de hamamélis*, Fr.; *Flüssiges Hamamelisextrakt*, G.

Preparation.—Hamamelis, in No. 40 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 300 Cc. of alcohol and 600 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of 300 Cc. of alcohol to 600 Cc. of water, until the hamamelis is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract;

dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of menstruum, composed of alcohol 7½ fluidounces, water 15 fluidounces, glycerin 2½ fluidounces, and the first 21 fluidounces of percolate set aside as reserve. Subsequent percolation is to be continued with a mixture of alcohol 3 volumes and water 6 volumes, and the final volume of finished product should be made up to 24 fluidounces.

The Br. P. directs a menstruum of 45 per cent. alcohol to be used for exhausting the leaves.

The fluidextract is of a brown color, and has the astringent and bitter taste of the leaves. The substitution of glycerin for a portion of the water yields a more permanent preparation.

Uses.—The use of this remedy is outlined under HAMAMELIDIS FOLIA (which see). The dose is from 10 to 30 minims (0.6-2 Cc.).

FLUIDEXTRACTUM HYDRASTIS, *U. S.*—Fluidextract of Hydrastis.

Extractum hydrastis liquidum—Liquid Extract of Hydrastis, Br.; *Extractum hydrastis fluidum,* P. G.—*Fluidextract of golden seal,* E.; *Extrait liquide de hydrastis,* Fr.; *Flüssiges Hydrastisextrakt,* G.; *Estratto di idraste liquido,* It.

Preparation.—Hydrastis, in No. 60 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 600 Cc. of alcohol and 300 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of 600 Cc. of alcohol to 300 Cc. of water, until the hydrastis is exhausted. Reserve the first 850 Cc. of the percolate. By means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of hydrastine in the remainder of the liquid; add to this sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 2 Gm. of hydrastine.

Assay of Fluidextract of Hydrastis.—Fluidextract of hydrastis, 10 Cc.; distilled water, potassium iodide, ammonia-water, ether, each a sufficient quantity. Measure 10 Cc. of the fluidextract into a 100 Cc. measuring flask, and add to it 85 Cc. of distilled water and 2 Gm. of potassium iodide; when this has dissolved, add sufficient water to make 100 Cc. and shake for several minutes. Then filter off 50 Cc. of the liquid into a separator. Render the liquid alkaline with ammonia, add 30 Cc. of ether, and shake at intervals during several minutes. Draw off the aqueous layer into a beaker, and then the ethereal portion into another tared beaker. Return the aqueous solution from the beaker to the separator, and shake it with 20 Cc. more of ether for a minute. Draw off and reject the aqueous layer, and then draw off the ethereal layer into the tared beaker. Allow the ether to evaporate at a gentle heat, dry the residue in the beaker to constant weight on a water-bath, and then weigh. The weight obtained, multiplied by 20, gives the weight in grammes of hydrastine contained in 100 Cc. of fluidextract of hydrastis.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum, composed of alcohol 14½ fluidounces, water 7¼ fluidounces, glycerin 2½ fluidounces, and the first 21 fluidounces of percolate set aside as reserve. Subsequent percolation is to be continued with a mixture of alcohol 2 volumes, water 1 volume.

The use of glycerin in the official menstruum is of decided advantage, and adds to the permanency of the preparation.

The liquid extract of the Br. P. is prepared with 45 per cent. alcohol. The P. G. directs the extraction of hydrastis with a mixture of 7 parts of alcohol and 3 parts of water, both by weight.

Fluidextract of hydrastis has a deep brown-yellow color and the strongly bitter taste of the root.

Uses.—The fluidextract forms a convenient method for administering the drug. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM HYOSCYAMI, *U. S.*—Fluidextract of Hyoscyamus.

Extrait liquide de jusquiame, Fr.; *Flüssiges Bilsenkrautextrakt*, G.

Preparation.—Hyoscyamus, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 2000 Cc. of alcohol with 1000 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the hyoscyamus is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 20 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of alkaloids in the remainder of the liquid; add to this sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 0.075 Gm. of alkaloids from hyoscyamus.

Assay of Fluidextract of Hyoscyamus.—The method to be employed is identical with that given for the assay of fluidextract of belladonna root, using, however, 50 Cc. of fluidextract of hyoscyamus instead of the quantity of fluidextract of belladonna root directed, and multiplying the product obtained by titration by 2 instead of 10, to get the number of grammes of mydriatic alkaloids contained in 100 Cc. of fluidextract of hyoscyamus.—U. S.

The larger quantity of fluidextract of hyoscyamus directed for the assay is necessary because the drug contains very much less alkaloid than belladonna. The coloring-matter present is apt to interfere somewhat with observation of the line of separation between the aqueous and chloroformic liquids, and some little practice is necessary for successful work.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum (alcohol 2 volumes, water 1 volume), and the first 20 fluidounces of percolate set aside as reserve.

The fluidextract is of a deep green-brown color, has the heavy odor of the drug, and keeps well.

Uses.—The employment of this remedy is described under HYOSCYAMUS (which see). The dose is from 5 to 10 minims (0.3–0.6 Cc.).

FLUIDEXTRACTUM IPECACUANHÆ, *U. S.*—Fluidextract of Ipecac.

Extractum Ipecacuanhæ Liquidum—Liquid Extract of Ipecacuanha, Br.—*Extrait liquide d'ipécacuanha*, Fr.; *Flüssiges Ipecacuanhaextrakt*, G.

Preparation.—Ipecac, in No. 80 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the ipecac is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of alkaloids in the remainder of the liquid; to this add sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 1.75 Gm. of alkaloids from ipecac.

Assay of Fluidextract of Ipecac.—Fluidextract of ipecac, 10 Cc.; normal sulphuric acid, ammonia-water, ether, tenth-normal sulphuric acid, fiftieth-normal potassium hydrox-

ide solution, hematoxylin test-solution, each a sufficient quantity. Measure 10 Cc. of fluidextract of ipecac in a graduated pipette, and transfer it to a porcelain evaporating dish. Evaporate off all the alcohol on a water-bath, and when almost cool add 5 Cc. of normal sulphuric acid, and stir until all the alkaloids have been dissolved. Filter into a separator, rinse the dish, and wash the filter successively with 10 Cc. and 5 Cc. of distilled water, and add these liquids to the separator. To the separator add 20 Cc. of ether and a small piece of red litmus-paper; render the liquid alkaline with ammonia-water, and shake for a minute. Draw off the lower aqueous layer into a beaker, and the ethereal layer into another beaker. Return the aqueous solution to the separator, and shake with 10 Cc. more of ether, adding the ethereal solution to that already in the beaker. After again returning the aqueous solution to the separator, shake again with 10 Cc. of ether, and then add the ethereal layer to that already in the beaker. Allow the combined ether-solutions to evaporate either spontaneously or with the aid of a water-bath, and then add 10 Cc. of tenth-normal sulphuric acid. Stir the liquid carefully with a glass rod to facilitate the solution of the alkaloids, and when these have all dissolved, add 5 drops of hematoxylin solution. From a graduated burette add sufficient fiftieth-normal potassium hydroxide solution to just cause the yellow color of the solution to turn purple. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 10 (the 10 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.0254, and this product by 10 (or multiply at once by 0.254), which will give the weight in grammes of alkaloids contained in each 100 Cc. of the fluidextract of ipecac.—U. S.

25 avoirdupois ounces of ipecac should be moistened with about 9 fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve.

The Br. P. demands that liquid extract of ipecac shall contain 2 to 2.25 Gm. of the alkaloids of ipecacuanha in 100 Cc., and is to be prepared as follows: Moisten 1 pound of ipecacuanha, in No. 20 powder, with 6 fluidounces of 90 per cent. alcohol; pack firmly in a percolator; add more of the alcohol, and when the liquid begins to drop close the lower orifice of the percolator; set aside for 24 hours. Then percolate slowly until 13½ fluidounces have been collected; reserve this portion. Continue percolation until nothing more is extracted; drain well. Mix 700 grains of calcium hydroxide with the marc; allow them to remain in contact for 24 hours; then continue percolation until exhaustion is complete. Recover the alcohol from the last two percolates by distillation; dissolve the residual extract in the reserved portion of percolate.

Determine the proportion of alkaloids in the resulting strong liquid extract by the following analytical process: Dilute 20 Cc. with an equal bulk of water. Remove the alcohol by the aid of a water-bath; add to the warm solution an excess of solution of lead subacetate. Filter; wash the precipitate with water and add the washings to the filtrate. Remove the excess of lead from the filtrate by precipitation with diluted sulphuric acid; filter; wash the precipitate with water and add the washings to the filtrate. Transfer the filtrate to a separator; add excess of ammonia-water and agitate with 25 Cc. of chloroform. Separate and set aside the chloroformic solution. Repeat twice the agitation with chloroform and the separation. Mix the chloroformic solutions; evaporate; dry at a temperature below 80° C. (176° F.), and weigh the residue of total alkaloids.

From the weight calculate the amount of alkaloids in the bulk of strong liquid extract, and add to the latter sufficient 90 per cent. alcohol to produce a liquid containing not less than 2 and not more than 2.25 Gm. of alkaloids in 100 Cc.

Fluidextract of ipecac is a thin dark reddish-brown liquid, having a slightly acrid, bitterish taste. It keeps well.

Uses.—The fluidextract of ipecac is not largely employed except in conjunction with other remedies. It possesses the expectorant and emetic properties of the drug, and may be given for the various conditions in which the latter is recommended. The dose, as an expectorant, is from 2 to 5 minims (0.10–0.3 Cc.); as an emetic, from 10 to 30 minims (0.6–2 Cc.).

FLUIDEXTRACTUM KRAMERIÆ, *U. S.*—Fluidextract of Krameria.

Fluidextract of rhatany, E.; *Extrait liquide de ratanhia*, Fr.; *Flüssiges Ratanhiaextrakt*, G.

Preparation.—Krameria, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol and pack it firmly in a cylindrical glass percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the krameria is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of krameria should be moistened with about 10 fluidounces of diluted alcohol, and the first 17½ fluidounces of percolate set aside as reserve; the fiual volume of finished product should be made up to 24 fluidounces.

Fluidextract of krameria is of a deep brownish-red color and strongly astringent taste.

Uses.—This preparation is employed for its astringent properties. See KRAMERIA. The dose is from 20 to 60 minims (1.3–4 Cc.).

FLUIDEXTRACTUM LAPPÆ, *U. S.*—Fluidextract of Lappa.

Fluidextract of burdock, E.; *Extrait liquide de bardane*, Fr.; *Flüssiges Klettenwurzelextrakt*, G.

Preparation.—Lappa, in No. 60 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed, gradually adding diluted alcohol, until the lappa is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum, and the first 19½ fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Experience has shown that diluted alcohol perfectly exhausts burdock root, yielding a very satisfactory preparation.

Uses.—This fluidextract may be substituted for the root. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM LEPTANDRÆ, *U. S.*—Fluidextract of Leptandra.

Extrait liquide de leptandra, Fr.; *Flüssiges Leptandraextrakt*, G.

Preparation.—Leptandra, in No. 60 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it moderately in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the leptandra is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of leptandra is of a dark reddish-brown color and has a very bitter taste.

Uses.—Fluidextract of leptandra may be employed as a purgative, but because of its disagreeable taste is rarely given. The dose is from 10 minims to 1 fluidrachm (0.6–4 Cc.).

FLUIDEXTRACTUM LOBELIÆ, *U. S.*—Fluidextract of Lobelia.

Extrait liquide de lobélie enflée, Fr.; *Flüssiges Lobelienextrakt, G.*

Preparation.—Lobelia, in No. 50 powder, 1000 Gm.; acetic acid, water, of each a sufficient quantity to make 1000 Cc. Mix 275 Cc. of acetic acid with 725 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of acetic acid and water as before, until the lobelia is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder at a temperature not exceeding 50 C. (122 F.) to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with 8½ fluidounces of a mixture of acetic acid 11 volumes and water 29 volumes, and the first 22 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The present fluidextract of lobelia is an entirely different preparation from that of 1890, the former hydro-alcoholic menstruum having been replaced by 10 per cent. acetic acid. It may be looked upon as a concentrated vinegar, being about 10 times as strong as the vinegar of lobelia of 1880 and containing about 60 per cent. more acetic acid. Fluidextract of lobelia is of a green-brown color and has the disagreeable acrid taste of the drug.

Uses.—This preparation represents fully the active properties of lobelia. The dose, as an expectorant, is from 1 to 5 minims (0.05–0.30 Cc.); as an emetic, 10 to 20 minims (0.60–1.30 Cc.).

FLUIDEXTRACTUM LUPULINI, *U. S.*—Fluidextract of Lupulin.

Extrait liquide de lupuline, Fr.; *Flüssiges Lupulinextrakt*, G.

Preparation.—Lupulin, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Pack the lupulin firmly in a cylindrical percolator; then add sufficient alcohol to saturate the lupulin and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the lupulin is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

From the percolation of 25 avoirdupois ounces of lupulin with alcohol the first 22 fluidounces obtained should be set aside as reserve, and the final volume of finished product made up to 24 fluidounces.

As pointed out by the late Alonzo Robbins in 1883, percolation of lupulin with alcohol proceeds more satisfactorily if the drug be not moistened before packing, as the moistened powder is apt to form a tough mass difficult to percolate, on account of the large proportion of resinous matter present. The fluidextract is of a deep red-brown color and has the characteristic odor and taste of lupulin.

Uses.—Fluidextract of lupulin is employed as an antispasmodic and nervous sedative in doses of from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM MATICO, *U. S.*—Fluidextract of Matico.

Extrait liquide de matico, Fr.; *Flüssiges Maticoblätterextrakt*, G.

Preparation.—Matico, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the matico is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of matico is a greenish-black liquid, having the characteristic aromatic odor of the leaves and a bitterish taste.

Uses.—The fluidextract represents the activity of the drug, and is the best form for internal administration. The dose is from 10 minims to 1 fluidrachm (0.6–4 Cc.).

FLUIDEXTRACTUM MEZEREI, *U. S.*—Fluidextract of Mezereum.

Extrait liquide de mézéréon (de garou), Fr.; *Flüssiges Seidelbastextrakt*, G.

Preparation.—Mezereum, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol and 200 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the mezereum is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of mezereum should be moistened with about 10 fluidounces of a mixture of alcohol 4 volumes and water 1 volume, and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Experience has shown that the addition of about one-fifth water to the former purely alcoholic menstruum yields an equally satisfactory preparation, and hence this change has been made. The fluidextract of mezereum is of green color and very acrid taste. It is rarely employed except as an addition to external remedies.

Solid extract of mezereum may be readily prepared by evaporation of the fluidextract in a porcelain capsule on a water-bath to the consistence of a soft residue, a pilular extract being impossible. The French Codex recognizes an ethereal extract of mezereum under the name *Extrait éthéré de garou*, which is made by first exhausting mezereum with alcohol, recovering the latter, treating the soft residue with ether, and evaporating the ethereal solution to a soft extract, the final yield being about 6 or 7 per cent.

Uses.—Fluidextract of mezereum may be locally employed as a counterirritant. Internally, it is rarely given. The internal dose is from 5 to 10 minims (0.3–0.6 Cc.).

FLUIDEXTRACTUM NUCIS VOMICÆ, *U. S.*—Fluidextract of Nux Vomica.

Extractum Nucis Vomicæ Liquidum—Liquid Extract of Nux Vomica, Br.—*Extrait liquide de noix vomique*, Fr.; *Flüssiges Brechnuszextrakt, Flüssiges Strychnossamenextrakt*, G.

Preparation.—Nux vomica, in No. 60 powder, 1000 Gm.; acetic acid, 50 Cc.; alcohol, water, of each a sufficient quantity. Mix alcohol and water in the proportion

of 750 Cc. of alcohol and 250 Cc. of water. Moisten the powder with 1000 Cc. of the mixture, to which the acetic acid has previously been added, and let it digest, in a well-covered vessel in a warm place, during 48 hours. Then pack it in a cylindrical glass percolator, gradually pour menstruum upon it, and allow the percolation to proceed slowly until the nux vomica is practically exhausted. Reserve the first 900 Cc. of the percolate, distil off the alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122 F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 20 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of strychnine in the remainder of the liquid, add to this sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 1 Gm. of strychnine.

Assay of Fluidextract of Nux Vomica.—Fluidextract of nux vomica, 20 Cc.; ammonia-water, ether, chloroform, distilled water, normal sulphuric acid, 3 per cent. sulphuric acid solution, 10 per cent. sodium hydroxide solution, nitric acid (specific gravity, 1.40), tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, iodeosin solution, of each a sufficient quantity. Transfer 20 Cc. of fluidextract of nux vomica to a porcelain dish, evaporate it to dryness by means of a water-bath, and dissolve the residue, while warm, in a mixture of 16 Cc. of ether, 5 Cc. of chloroform, and 4 Cc. of ammonia-water, and transfer the solution to a separator, rinsing the dish with a little chloroform, which is to be added to the separator, and shake the separator carefully for a few minutes. When the liquids have separated, draw off the aqueous layer into another separator, washing the chloroform-ether liquid and separator with a little water, and adding this to the second separator. Then shake the aqueous liquid with two successive portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a small portion of the liquid left in the second separator still shows, after acidifying, a reaction with mercuric potassium iodide test-solution, repeat the shaking out with 10 Cc. more of chloroform. Now shake the combined liquids in the first separator with three successive portions, respectively, of 15, 10, and 10 Cc. of normal sulphuric acid, and collect the combined acid solutions in another separator. To this acid solution add a small piece of red litmus-paper and sufficient ammonia-water to render it alkaline, then shake out successively with three portions, respectively, of 25, 10, and 10 Cc. of chloroform, and collect the chloroform solutions in a beaker. Evaporate the chloroform with the aid of a water-bath, dissolve the alkaloidal residue in 15 Cc. of 3 per cent. sulphuric acid by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cooled mixture of equal volumes of nitric acid (specific gravity, 1.40) and distilled water, and, after rotating the liquid a few times, set it aside for exactly 10 minutes, stirring it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous 10 per cent. sodium hydroxide solution, wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not quite turbid, add 2 Cc. more of the sodium hydroxide solution. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a beaker. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the beaker, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue add 10 Cc. of tenth-normal sulphuric acid, 5 drops of iodeosin test-solution, about 80 Cc. of water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide solution until the aqueous liquid just turns pink. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 10 (the 10 Cc. of tenth-normal sulphuric acid used), multiply the remainder by 0.0332, and this product by 5 (or multiply at once by 0.165), which will give the weight in grammes of strychnine contained in 100 Cc. of the fluidextract of nux vomica.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with a mixture of 16 fluidounces of alcohol, 8 fluidounces of water, and 1¼ fluidounces of acetic acid in a warm place for 48 hours, transferred to a percolator, and afterward percolated with a mixture of alcohol 3 volumes and water 1 volume, 20 fluidounces being set aside as reserve.

Since fluidextract of nux vomica is but little used and of exactly one-fifth the strength of the powdered extract, small quantities of it may be prepared, as wanted, by dissolving 5 Gm. of the extract in sufficient menstruum (alcohol 3 volumes, water 1 volume) to produce 25 Cc. of solution.

The British liquid extract of nux vomica is 50 per cent. stronger than that of the U. S. P. It is made by exhausting the drug in No. 20 powder with 70 per cent. alcohol as follows: After macerating 500 Gm. of the powder with 250 Cc. of menstruum for 6 hours, pack it firmly in a percolator, saturate with menstruum, and allow to macerate for 24 hours; continue slow percolation until 375 Cc. have been collected and set this aside as strong percolate. Continue the percolation until about 1875 Cc. of menstruum have been employed, or until the drug is exhausted. Concentrate the weak percolate to 31 Cc., add 93 Cc. of 90 per cent. alcohol, and add this mixture to the reserved portion. After 24 hours' rest, filter the liquid. Evaporate 10 Cc. of the filtered liquid to a thick syrupy consistence and dissolve in 20 Cc. of water, heating if necessary; transfer the solution to a separator and add 5 Gm. of sodium carbonate dissolved in 25 Cc. of water, and also 10 Cc. of chloroform Shake well, draw off the chloroformic solution, and repeat the treatment twice with the same quantity of chloroform. Treat the united chloroformic liquids with 3 successive portions of 2 Cc. of diluted sulphuric acid mixed with 8 Cc. of water. Mix the acid liquids and dilute with 175 Cc. of water, transfer to a flask, add 25 Cc. of 5 per cent. potassium ferrocyanide solution, shake the mixture well for ½ hour, and allow to stand for 6 hours. The resulting precipitate is transferred to a small filter, the last portions being rinsed out with water containing $\frac{1}{40}$ of its volume of diluted sulphuric acid, and washed until free from bitterness. Having rinsed the precipitate into a separator, 5 Cc. of ammonia-water are added, the mixture well shaken, and then shaken out with 2 successive portions of 15 Cc. of chloroform. The united chloroformic liquids are evaporated in a tared dish and the residue dried for 1 hour on a water-bath. From the weight of the dried residue the amount of strychnine in the strong liquid extract is calculated, and to the latter sufficient 70 per cent. alcohol is added to produce a liquid extract containing 1.5 Gm. of strychnine in 100 Cc.

Uses.—Fluidextract of nux vomica is rarely administered, the tincture being preferred. The dose is from 1 to 5 minims (0.05–0.30 Cc.).

FLUIDEXTRACTUM PAREIRÆ, *U. S.*—Fluidextract of Pareira.

Extractum pareiræ liquidum, Br.—*Liquid extract of pareira*, E.; *Extrait liquide de pareira brava*, Fr.; *Flüssiges Pareiraextrakt*, G.

Preparation.—Pareira, in No. 40 powder, 1000 Gm.; glycerin, 100 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 600 Cc. of alcohol and 300 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of 600 Cc. of alcohol to 400 Cc. of water, until the pareira is exhausted. Reserve the first 850 Cc. of the percolate. By means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum composed of alcohol 6 fluidounces, water 3 fluidounces, glycerin 1 fluidounce, and the first 21 fluidounces of percolate set aside as reserve. Subsequent percolation should be continued with a mixture of alcohol 6 volumes, water 4 volumes, and the final volume of finished product made up to 24 fluidounces.

The liquid extract of pareira of the Br. P. is prepared by exhausting the root in No. 40 powder, with boiling distilled water, first by maceration and then by percolation, collecting about 10 times as much infusion as weight of drug. After determining the percentage of extractive in the percolate, the latter is evaporated until the residual liquid contains one-third its weight of extractive, and is then mixed with sufficient 90 per cent. alcohol to produce from 3 volumes of the evaporated liquid 4 volumes of liquid extract. If necessary the mixture is filtered.

Fluidextract of pareira is of a brown color, and possesses the peculiar bitter taste of the root in a marked degree. The change in the official menstruum, by increasing the

proportion of water from 18 to 30 per cent., has been found advisable, since the drug is exhausted thoroughly and the finished product keeps well.

The British preparation is practically a concentrated infusion preserved by one-fourth its volume of alcohol.

Uses.—The fluidextract may be given for the various conditions in which pareira brava is recommended. The dose is from 1 to 2 fluidrachms (4–8 Cc.).

FLUIDEXTRACTUM PHYTOLACCÆ, *U. S.*—Fluidextract of Phytolacca.

Fluidextract of poke root, E.; *Extrait liquide du racine de phytolaque*, Fr.; *Flüssiges Kermesbeerenwurzelextrakt*, G.

Preparation.—Phytolacca root, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of the mixture, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the phytolacca root is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of diluted alcohol, and the first 19½ fluidounces of percolate set aside as reserve. The final volume of finished product should be made up to 24 fluidounces.

Experience has shown that diluted alcohol exhausts poke root as well as the stronger menstruum (alcohol 2 volumes, water 1 volume) formerly used, and as the finished product keeps well, the change seems desirable.

Uses.—Fluidextract of poke may be employed as the most eligible preparation. As an alterative the dose is from 2 to 5 minims (0.10–0.3 Cc.); as an emetic, from 10 to 30 minims (0.6–2 Cc.).

FLUIDEXTRACTUM PILOCARPI, *U. S.*—Fluidextract of Pilocarpus.

Extractum jaborandi liquidum—Liquid extract of jaborandi, Br.; *Fluidextract of jaborandi*, E.; *Extrait liquide de jaborandi*, Fr.; *Flüssiges Jaborandiextrakt*, G.

Preparation.—Pilocarpus, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the pilocarpus is exhausted. Reserve the first 750 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of alkaloids in the remainder of the liquid; add to this sufficient menstruum to make each 100 Cc. of fluidextract contain 0.4 Gm. of the alkaloids from pilocarpus.

Assay of Fluidextract of Pilocarpus.—Fluidextract of pilocarpus, 10 Cc.; chloroform, ammonia-water, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, cochineal or iodeosin test-solution, of each a sufficient quantity. Transfer 10 Cc. of fluidextract of pilocarpus to a porcelain dish containing a little clean sand, and evaporate it to dryness by means of a water-bath. Mix the sand uniformly with the extract and transfer the mixture to an Erlenmeyer flask of about 200 Cc. capacity, rinsing the dish with 25 Cc. of chloroform and transferring the rinsings to the flask. Add to the latter 2.5 Cc. of ammonia-water, cork the flask securely, and shake it well at intervals during 1 hour. Filter the contents of the flask into a separator, rinsing the flask, and filter with a little chloroform, and adding the rinsings to the separator. Then shake out the chloroform solution with 15 Cc. of normal sulphuric acid, drawing off the acid aqueous solution into another sepa-

rator. Repeat the shaking out with a mixture of 5 Cc. of normal sulphuric acid and 5 Cc. of distilled water, collecting the acid solutions in the second separator. Again repeat the shaking out with 10 Cc. of distilled water, and add the aqueous liquid to the second separator. Introduce into the second separator a small piece of red litmus-paper, add enough ammonia-water to render the liquid alkaline, and extract the liquid with 20 Cc. of chloroform, drawing off the chloroformic solution into a beaker. Repeat the shaking out with 2 portions of 15 and 10 Cc. each of chloroform, and add the chloroformic solutions to the beaker. Evaporate the chloroform by means of a water-bath, and dissolve the alkaloidal residue in 5 Cc. of tenth-normal sulphuric acid. Add 5 drops of cochineal or iodeosin test-solution, and titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid used), and multiply the remainder by 0.02, and this product by 10 (or multiply at once by 0.2), to obtain the weight in grammes of alkaloids contained in 100 Cc. of the fluidextract of pilocarpus.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of menstruum, and the first 17½ fluidounces of percolate set aside as reserve.

Fluidextract of jaborandi is of a greenish-red-brown color.

The liquid extract of the Br. P. is practically identical with the above, being made by percolation with 45 per cent. alcohol, but no definite alkaloid content is demanded.

Uses.—This is the best preparation of the leaves to employ. It is, however, inferior to the alkaloid. The dose is from 10 to 30 minims (0.6–2 Cc.).

FLUIDEXTRACTUM PODOPHYLLI.—Fluidextract of Podophyllum.

Fluidextract of May-apple or of mandrake, E.; *Extrait liquide de podophylle*, Fr.; *Flüssiges Podophyllumextrakt*, G.

Preparation.—Podophyllum, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the podophyllum is exhausted. Reserve the first 850 Cc. of the percolate; by means of a water-bath distil off the alcohol from the remainder; dissolve the residue in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum (alcohol 4 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The fluidextract is of a dark brown-red color. It may be conveniently used for the extemporaneous preparation of the solid extract of podophyllum.

Uses.—The fluidextract possesses all of the medicinal properties of the root, but it is rarely employed. The dose is from 5 to 20 minims (0.3–1.3 Cc.).

FLUIDEXTRACTUM PRUNI VIRGINIANÆ, *U. S.*—Fluidextract of Wild Cherry.

Extrait liquide d'écorce de cerisier de Virginie, Fr.; *Flüssiges Wildkirschenrindenextrakt*, G.

Preparation.—Wild cherry, in No. 30 powder, 1000 Gm.: glycerin, alcohol, and water, each a sufficient quantity to make 1000 Cc. Mix 200 Cc. of glycerin and 200 Cc. of alcohol with 600 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical glass percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of 200 Cc. of alcohol to 800 Cc. of water, and allow the percolation to proceed very slowly until the fluidextract measures 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 8 fluidounces of menstruum (glycerin 5 fluidounces, alcohol 5 fluidounces, water 15 fluidounces), and, finally, continue percolation with a mixture of alcohol 1 volume and water 4 volumes until 24 fluidounces of fluidextract have been obtained.

This is one of those troublesome fluidextracts the formula of which has been changed since its introduction in each subsequent edition of the Pharmacopœia. The one suggested by Prof. Procter in 1859, in which the bark was exhausted by alcohol, and after the evaporation of the menstruum the decomposition of amygdalin was effected by emulsion of almonds, was an efficient and elegant preparation, but objected to on account of troublesome manipulation. The present official menstruum is a decided improvement on that directed by the 1890 Pharmacopœia, and the resulting preparation mixes clear with aqueous and weakly alcoholic liquids, which was impossible with the former fluidextract on account of the strong alcohol used.

Fluidextract of wild cherry is of a deep brownish-red color, and when recently made has the odor of bitter-almond oil in a marked degree, and possesses also the astringent and pleasantly bitter taste of the bark. The odor slowly diminishes upon standing.

Uses.—The fluidextract is the most active preparation of wild cherry bark. Because of its concentration it is more easily administered than the other preparations. It is frequently prescribed in cough mixtures in doses of from 15 to 60 minims (1–4 Cc.).

FLUIDEXTRACTUM QUASSIÆ.—Fluidextract of Quassia.

Extrait liquide de quassie, Fr.; *Flüssiges Quassiaextrakt*, G.

Preparation.—Quassia, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 300 Cc. of alcohol with 600 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the quassia is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum, alcohol 1 volume, water 2 volumes, and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The bitter principle of quassia is perfectly soluble in water, and the fluidextract made with the official menstruum will probably keep as well as that made with diluted alcohol, as directed in 1880. We have had no experience with the present menstruum. The fluidextract has a brown-yellow color and a persistently bitter taste.

Uses.—For the effects and uses of this preparation, see QUASSIA. The dose is from 15 to 30 minims (1–2 Cc.).

FLUIDEXTRACTUM QUERCUS, *U. S.*—Fluidextract of Quercus.

Fluidextract of white-oak bark, E.; *Extrait liquide d'écorce du chêne*, Fr.; *Flüssiges Eichenrindenextrakt*, G.

Preparation.—Quercus, in No. 40 powder, 1000 Cc.; glycerin, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of diluted alcohol, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the quercus is exhausted. Reserve the first 700 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of powdered white-oak bark should be moistened with about 10 fluidounces of a menstruum composed of glycerin 2½ fluidounces and diluted alcohol 22½ fluidounces; subsequent percolation is to be continued with diluted alcohol. The first 19½ fluidounces of percolate are to be set aside as reserve, and the final volume of finished product brought up to 24 fluidounces.

Fluidextract of quercus is one of the newly introduced preparations of the Pharmacopœia. It has a reddish-brown color, a very astringent taste, but little or no odor. A fluidextract of red-oak bark is marketed by manufacturers, but is not officially recognized.

Uses.—This preparation is useful in diarrhœa and other conditions in which it is desired to administer quercus internally. Dose, 15 to 60 minims (1–4 Cc.). See QUERCUS.

FLUIDEXTRACTUM QUILLAJÆ, *U. S.*—Fluidextract of Quillaja.

Fluidextract of soap-bark, E.; *Extrait liquide d'écorce de quillaya*, Fr.; *Flüssiges Seifenrindenextrakt*, G.

Preparation.—Quillaja, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 400 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding diluted alcohol, until the quillaja is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with about 10 fluidounces of diluted alcohol, and the first 20 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The value of fluidextract of soap-bark in pharmacy is questionable, since its use in medicine is very limited on account of its toxic properties. The fluidextract is of a brownish color, has a slight odor, and a disagreeable acrid taste. It froths considerably when shaken alone or diluted with water.

Uses.—This fluidextract fully represents the properties of the drug. See QUILLAJA.

FLUIDEXTRACTUM RHAMNI PURSHIANÆ, *U. S.*—Fluidextract of Rhamnus Purshiana.

Extractum cascaræ sagradæ liquidum, Br.; *Liquid extract of cascara sagrada*, E.; *Extrait liquide de cascara sagrada*, Fr.; *Flüssiges Cascara Sagradaextrakt*, G.

Preparation.—Rhamnus purshiana, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 400 Cc. of alcohol with 600 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the rhamnus purshiana is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum, composed of alcohol 4 volumes and water 6 volumes, and the first 20 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The Br. P. directs that 20 ounces of cascara sagrada in No. 20 powder shall be moistened with three-fourths of its weight of cold distilled water and set aside for 6 hours; then place it loosely in a percolator and percolate with more distilled water until the powder is exhausted; evaporate the percolate to 12 fluidounces; add 4 fluidounces of 90 per cent. alcohol, previously mixed with sufficient distilled water to make up the volume of the mixed liquids to 20 fluidounces.

The reduction of the alcoholic strength of the official menstruum is in accord with the experience that cold water alone will extract all the virtues of rhamnus purshiana.

In our experience an equally efficient fluidextract can be prepared with a mixture of 1 volume of alcohol and 3 volumes of water. Percolation with cold water, as directed in the British formula, is not desirable in this country, especially in warm weather, as fermentation is apt to set in.

Fluidextract of rhamnus purshiana is of a very dark, reddish-brown color and has an intensely bitter taste; hence it has been almost entirely superseded by the next following preparation.

Uses.—For the effects and uses of this preparation, see RHAMNUS PURSHIANA. The dose is from 15 to 60 minims (1–4 Cc.).

FLUIDEXTRACTUM RHAMNI PURSHIANÆ AROMATICUM, *U. S.*—Aromatic Fluidextract of Rhamnus Purshiana.

Aromatic fluidextract of cascara sagrada, Tasteless fluidextract of cascara sagrada, E.; *Extrait liquide aromatique de cascara sagrada*, Fr.; *Bitterloses flüssiges Cascara-Sagrada-extrakt*, G.

Preparation.—Rhamnus purshiana, in No. 40 powder, 1000 Gm.; glycyrrhiza, in No. 30 powder, 100 Gm.; magnesium oxide, 125 Gm.; glycerin, 250 Cc.; compound spirit of orange, 10 Cc.; alcohol, diluted alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the rhamnus purshiana, glycyrrhiza, and magnesium oxide thoroughly, and, having added 2000 Cc. of water, allow the mixture to macerate for 12 hours, and then dry it at a gentle heat with the aid of a water-bath. Mix the glycerin with 500 Cc. of alcohol and 250 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the powder is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, add the compound spirit of orange and enough diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of powdered rhamnus purshiana should be mixed with 2½ avoirdupois ounces of powdered licorice root and 3 avoirdupois ounces of magnesium oxide, and then well moistened with 48 fluidounces of water and allowed to macerate for 12 hours. After drying the mixture with a gentle heat, it is moistened with 10 fluidounces of the menstruum composed of 6 fluidounces each of glycerin and water and 12 fluidounces of alcohol, percolation being finally completed with diluted alcohol. The first 20 fluidounces of percolate are to be set aside as reserve, and the final product made up to 24 fluidounces.

Aromatic fluidextract of cascara sagrada is one of the new preparations of the Pharmacopœia, although it has been in use for a number of years, and is much preferred on account of its more pleasant taste. Not only does the treatment with magnesia destroy the intensely bitter taste of the cascara bark, but the addition of licorice and compound spirit of orange adds to the palatableness of the preparation. It has been stated that maceration with water and subsequent drying before moistening with menstruum are not essential for the complete destruction of the bitter taste, but in our experience this modification of the process is not satisfactory. Slaked lime has also been suggested in place of magnesia, but has been found less efficient and yields an inferior preparation. The finished fluidextract is a heavy liquid of deep reddish-brown color, almost black when undiluted, and has a pleasant sweetish taste.

Uses.—The action and dose of this drug are the same as of the preceding. Its pleasant taste enhances its value. Dose, 15 to 60 minims (1–4 Cc.).

FLUIDEXTRACTUM RHEI, *U. S.*—Fluidextract of Rhubarb.

Extrait liquide de rhubarbe, Fr.; *Flüssiges Rhabarberextrakt*, G.

Preparation.—Rhubarb, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and

leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the rhubarb is exhausted. Reserve the first 750 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 70° C. (158° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum (alcohol 8 volumes, water 2 volumes), and the first 18½ fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

This fluidextract has undergone considerable modifications. The root, exhausted by an alcoholic menstruum, and the liquid, after the evaporation of the alcohol, preserved by sugar, resulted in a fluidextract which was very thick and deposited considerably. A fluidextract prepared with cold water and preserved by sugar, as recommended by George Bille (1872), is free from the last-mentioned objection, but, it was claimed, though fairly active, not to contain *all* the purgative principles of rhubarb. The use of glycerin with an alcoholic menstruum proved a failure with the fluidextract, as it did with the tincture, the liquids, although clear for a time, precipitating more copiously afterward. The present menstruum yields a fluidextract which precipitates only very slightly, and is almost identical with that proposed by A. Robbins in 1883; a fluidextract thus prepared retained its fluidity for nearly four years. None of these different fluidextracts will yield clear mixtures with aqueous liquids unless an alkali be added. Fluidextract of rhubarb is of a blackish red-brown color, and has the odor and taste of the drug.

Uses.—For the effects and uses of this preparation, see RHEUM. The dose is from 15 to 30 minims (1–2 Cc.).

FLUIDEXTRACTUM RHOIS GLABRÆ, *U. S.*—Fluidextract of Rhus Glabra.

Fluidextract of sumach berries, E.; *Extrait liquide de fruit de sumac*, Fr.; *Flüssiges Sumachbeerenextrakt*, G.

Preparation.—Rhus glabra, in No. 40 powder, 1000 Gm.; glycerin, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of diluted alcohol, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the rhus glabra is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of a menstruum composed of diluted alcohol 22½ fluidounces and glycerin 2½ fluidounces; subsequent percolation is to be continued with diluted alcohol. The first 19½ fluidounces of percolate should be set aside as a reserve, and the final volume of finished product made up to 24 fluidounces.

The fluidextract is of a deep-red color, and has a pleasant acidulous and astringent taste.

Uses.—For the effects and uses of this preparation, see RHUS GLABRA. The dose is from 15 to 30 minims (1–2 Cc.).

FLUIDEXTRACTUM ROSÆ, *U. S.*—Fluidextract of Rose.

Fluidextract of red rose, E.; *Extrait liquide de rose rouge*, Fr.; *Flüssiges Essigrosenextrakt*, G.

Preparation.—Red rose, in No. 20 powder, 1000 Gm.; glycerin, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of diluted alcohol, and, having moistened the powder with 400 Cc. of the mixture, pack

it firmly in a cylindrical glass percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the red rose is exhausted. Reserve the first 750 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of a menstruum composed of dilute alcohol 21½ fluidounces and glycerin 2½ fluidounces; subsequent percolation is to be continued with diluted alcohol. The first 18½ fluidounces of percolate should be set aside as reserve, and the final volume of finished product made up to 24 fluidounces.

This fluidextract is of a deep-red color, of an agreeable odor of rose, and of a pleasant mildly astringent taste.

Uses.—For the uses of this preparation, see ROSA GALLICA. Dose, 1 to 2 drachms (4–8 Cc.).

FLUIDEXTRACTUM RUBI, *U. S.*—Fluidextract of Rubus.

Fluidextract of blackberry-bark, E.; *Extrait liquide d'écorce de ronce*, Fr.; *Flüssiges Brombeerrindenextrakt*, G.

Preparation.—Rubus, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of diluted alcohol and pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the rubus is exhausted. Reserve the first 800 Cc. of the percolate; by means of a water-bath distil off the alcohol from the remainder and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of diluted alcohol. The first 19½ fluidounces of percolate should be set aside as a reserve, and the final volume of finished product made up to 24 fluidounces.

As the menstruum directed by the 1890 Pharmacopœia did not produce an entirely satisfactory preparation, it was thought that on account of the astringent principle present in the drug an increase in the proportion of glycerin might prove advantageous, but experience has shown that a fluidextract made with diluted alcohol alone keeps better than when made with any other menstruum. Fluidextract of rubus is of a deep-brown color, and has a decidedly astringent taste.

Uses.—For the effects and uses of this preparation, see RUBUS. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM SABINÆ, *U. S.*—Fluidextract of Savine.

Extrait liquide de sabine, Fr.; *Flüssiges Sadebaumextrakt*, G.

Preparation.—Savine, in No. 40 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 250 Cc. of alcohol, and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the savine is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 6 fluidounces of menstruum, and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of savine is a brown-green liquid containing the volatile oil, resin, and

tannin of the drug, and is not only well adapted for making Ceratum Sabinæ, but it offers likewise a convenient way for administering savine.

EXTRACTUM SABINÆ is made with 60 per cent. alcohol (Fr. Codex), the tincture being evaporated to the proper consistence; it has a greenish-brown color. The yield is 19 or 20 per cent.

Uses.—Fluidextract of savine is rarely employed internally. It may be applied externally in the form of a cerate or ointment. The internal dose is from 5 to 10 minims (0.3–0.6 Cc.).

FLUIDEXTRACTUM SANGUINARIÆ, *U. S.*—Fluidextract of Sanguinaria.

Fluidextract of blood-root, E.; *Extrait liquide de sanguinaire*, Fr.; *Flüssiges Blutwurzelextrakt*, G.

Preparation.—Sanguinaria, in No. 30 powder, 1000 Gm.; acetic acid, water, of each a sufficient quantity to make 1000 Cc. Mix 275 Cc. of acetic acid with 725 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, allow it to macerate, in a well-covered vessel, during 48 hours. Then pack it firmly in a cylindrical percolator, gradually pour menstruum upon it, using the same proportions of acetic acid and water as before, and allow the percolation to proceed slowly until the sanguinaria is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered root should be moistened with 7½ fluidounces of a mixture of acetic acid 11 volumes and water 29 volumes, and allowed to macerate for 48 hours before percolation. The first 21 fluidounces of percolate are set aside as reserve, and the final volume of fluidextract made up to 24 fluidounces.

The menstruum for this fluidextract has been greatly changed in the present formula, and the finished product now represents a concentrated vinegar of sanguinaria ten times as strong as that of 1880, and containing about 60 per cent. more acetic acid. Although the acetous menstruum will extract all the active principles of the drug, precipitation will take place as heretofore, and it is questionable whether the preparation will keep better, or even as well, as that of 1890. Fluidextract of sanguinaria is of a very deep-red color and has an acetous odor and a sour, somewhat acrid taste.

Uses.—Dose, 3 to 5 minims (0.20–0.30 Cc.). See SANGUINARIA.

FLUIDEXTRACTUM SARSAPARILLÆ, *U. S.*—Fluidextract of Sarsaparilla.

Extractum sarsæ liquidum, Br.—*Liquid extract of sarsaparilla*, E.; *Extrait liquide de salsepareille*, Fr.; *Flüssiges Sarsaparillaextrakt*, G.

Preparation.—Sarsaparilla, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 300 Cc. of alcohol with 600 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the sarsaparilla is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of menstruum (alcohol 1 volume, water 2 volumes), and the first 19½ fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Liquid extract of sarsaparilla of the Br. P. is made with 20 per cent. alcohol in the following manner: 20 ounces of the root, in No. 40 powder, are divided into 3 portions. One portion is moistened with 4 fluidounces of the alcohol, packed in a percolator, set aside for 24 hours, and then percolated with more of the alcohol, until 4 fluidounces of liquid have been obtained. The second portion of drug is moistened with the first percolate, packed in a percolator, set aside for 24 hours, and then percolated with a men-

struum obtained by further percolation of the first portion; 4 fluidounces of percolate are collected and used to moisten the third portion of the drug. The mixture is packed in a percolator, set aside for 24 hours, and then percolated with a menstruum obtained by successive percolation through the first and second portions of drug. From the third portion of drug 18 fluidounces of percolate are collected, which are then mixed with 2 fluidounces of glycerin, making a total of 20 fluidounces.

The relative strength of the two fluidextracts is practically the same. The first process appears to be well adapted for exhausting the root and preserving the fluidextract, which contains about one-third its measure of alcohol. The second formula directs repercolation and employs a menstruum containing about two-thirds as much alcohol as that of the U. S. P., the final addition of glycerin being made for the purpose of preventing deposit upon standing.

Uses.—Fluidextract of sarsaparilla is employed for the same purposes as the drug from which it is prepared. Its principal use, however, is as a vehicle for other remedies. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM SARSAPARILLÆ COMPOSITUM, *U. S.*—Compound Fluidextract of Sarsaparilla.

Extrait liquide de salsepareille composé, Fr.; *Zusammengesetztes flüssiges Sarsaparillaextrakt*, G.

Preparation.—Sarsaparilla, in No. 30 powder, 750 Gm.; glycyrrhiza, in No. 30 powder, 120 Gm.; sassafras bark, in No. 30 powder, 100 Gm.; mezereum, in No. 30 powder, 30 Gm.; glycerin, 100 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Mix the glycerin with 900 Cc. of diluted alcohol, and, having moistened the mixed powders with 400 Cc. of the mixture, pack them firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol and water, until the powder is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the mixed ground drugs should be moistened with about 10 fluidounces of a menstruum composed of diluted alcohol 22½ fluidounces and glycerin 2½ fluidounces, subsequent percolation being continued with diluted alcohol. The first 20 fluidounces of percolate should be set aside as reserve, and the final volume of finished product made up to 24 fluidounces.

The present official menstruum contains about 50 per cent. more alcohol than that of 1890, and has proved more satisfactory. The preparation deposits but slightly. The frequent use which is made of the above combination of drugs probably renders such a fluidextract desirable, though it seems to be unnecessary, since the introduction of concentrated preparations of licorice-root and mezereum affords the opportunity of giving these and sarsaparilla in any proportion that may be desired.

Uses.—This preparation has been used as a substitute for the compound decoction of sarsaparilla. It is probably equally efficient, and because of its concentration is administered with much less difficulty. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM SCILLÆ, *U. S.*—Fluidextract of Squill.

Extrait liquide de scille, Fr.; *Flüssiges Meerzwiebelextrakt*, G.

Preparation.—Squill, in No. 20 powder, 1000 Gm.; acetic acid, water, each a sufficient quantity to make 1000 Cc. Mix 275 Cc. of acetic acid with 725 Cc. of water, and, having added 800 Cc. of the mixture to the powder, allow it to macerate, in a well-covered glass or porcelain vessel, during 48 hours, then transfer it to a conical glass percolator, and allow the percolation to proceed slowly, adding menstruum gradually, using the same proportions of acetic acid and water as before, until the fluidextract measures 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with 20 fluidounces of a mixture of 11 volumes of acetic acid and 29 volumes of water, and allowed to macerate

for 48 hours, after which the mass is percolated with the same menstruum until 24 fluidounces have been obtained.

The menstruum for fluidextract of squill has been radically changed, the present preparation representing an acetous fluidextract of ten times the strength of the official vinegar of squill, and containing about 60 per cent. more acetic acid. Squill will absorb much of the watery menstruum and swell considerably, hence uniform percolation will be found difficult, as the particles of drug are apt to cake together.

Fluidextract of squill is a yellowish, somewhat syrupy liquid of decided acetous odor and a bitter and very sour taste.

Uses.—This preparation may be employed whenever squills is indicated. The dose is from 2 to 3 minims (0.10–0.20 Cc.). See SCILLA.

FLUIDEXTRACTUM SCOPOLÆ, *U. S.*—Fluidextract of Scopola.

Extrait liquide de racine de scopola, Fr.; *Flüssiges Skopolawurzelextrakt*, G.

Preparation.—Scopola, in No. 40 powder, 1000 Gm.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 350 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the scopola is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° Cc. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained ascertain, by calculation, the amount of mydriatic alkaloids in the remainder of the liquid, and add to this sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 0.5 Gm. of the mydriatic alkaloids from scopola root.

Assay of Fluidextract of Scopola.—The method to be employed is identical with that given under FLUIDEXTRACT OF BELLADONNA ROOT.—U. S.

25 avoirdupois ounces of the powdered root should be moistened with about 9 fluidounces of the menstruum (alcohol 4 volumes, water 1 volume), and the first 22 fluidounces of the percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

This is one of the new fluidextracts introduced into the Pharmacopœia of 1900. It resembles fluidextract of belladonna root in every particular, having also the same composition. Fluidextract of scopola may be used for the preparation of the solid extract by evaporating a convenient quantity to a pilular consistence, at a low temperature on a water-bath.

Uses.—The action of this preparation is closely allied to that of BELLADONNA (which see). The dose is from 1 to 5 minims (0.05–0.30 Cc.).

FLUIDEXTRACTUM SCUTELLARIÆ, *U. S.*—Fluidextract of Scutellaria.

Fluidextract of skull-cap, E.; *Extrait liquide de scutellaire*, Fr.; *Flüssiges Helmkrautextrakt*, G.

Preparation.—Scutellaria, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 350 Cc. of the menstruum, and pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum until the scutellaria is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 9 fluidounces of

menstruum, and the first 20 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The fluidextract will have a green-brown color.

Uses.—This preparation is rarely employed. It represents all the medicinal properties of the drug. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM SENEGÆ, *U. S.*—Fluidextract of Senega.

Extrait liquide de polygale de Virginie, Fr.; *Flüssiges Senegaextrakt*, G.

Preparation.—Senega, in No. 40 powder, 1000 Gm.; solution of potassium hydroxide, 30 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the solution of potassium hydroxide with 600 Cc. of alcohol and 300 Cc. of water, and, having moistened the powder with 450 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of 600 Cc. of alcohol to 300 Cc. of water, until the senega is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10½ fluidounces of a menstruum composed of alcohol 16 fluidounces, water 8 fluidounces, and solution of potassium hydroxide 6 fluidrachms, subsequent percolation to be continued with a mixture of alcohol 2 volumes, water 1 volume. The first 21 fluidounces of percolate should be set aside as reserve, and the final volume of finished product made up to 24 fluidounces.

Water is a better solvent for senegin than a strongly alcoholic menstruum, but it has also the disadvantage of dissolving a considerable proportion of various pectin compounds, which are apt after some time to convert the liquid into a gelatinous mass.

The present formula for fluidextract of senega differs slightly from that of the last Pharmacopœia, inasmuch as the ammonia-water has been replaced in the menstruum by a smaller quantity of potassium hydroxide solution, the object being, however, the same, namely, to prevent gelatinization in the finished product. The fluidextract is of a dark-brown color, and possesses the characteristic odor and acrid taste of the root.

Extractum Senegæ.—*Extract of senega*, E.; *Extrait de polygale, Extrait de sénéca*, Fr.; *Senegaextrakt*, G.—The French Codex orders alcohol of specific gravity 0.914, which yields from 16 to 20 per cent. of extract. It may be prepared extemporaneously by evaporating the fluidextract to the proper consistence.

Uses.—Fluidextract of senega may be used for all the conditions in which senega is recommended. The dose is from 2 to 10 minims (0.10–0.6 Cc.).

FLUIDEXTRACTUM SENNÆ, *U. S.*—Fluidextract of Senna.

Extrait liquide de séné, Fr.; *Flüssiges Sennaextrakt*, G.

Preparation.—Senna, in No. 40 powder, 1000 Gm.; alcohol, diluted alcohol, each a sufficient quantity to make 1000 Cc. Moisten the senna with 350 Cc. of alcohol, pack it firmly in a percolator, and percolate it with alcohol until it is practically exhausted by this menstruum. The alcoholic percolate thus obtained is rejected, and the alcohol may be recovered therefrom by distillation. Then take out the moist powder and dry it, and moisten with 400 Cc. of diluted alcohol; pack it firmly in a cylindrical percolator and add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the senna is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

After exhausting 25 avoirdupois ounces of senna with alcohol, the powder, having been dried, should be moistened with about 10 fluidounces of diluted alcohol, and the

first 20 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The present fluidextract of senna is quite different from that of the 1890 Pharmacopœia, inasmuch as the drug is first treated with alcohol for the purpose of removing odorous resinous matter, which causes griping. Diluted alcohol has been found to extract all the active virtues of senna and to preserve the finished product well. The fluidextract has a dark-brown color and characteristic taste.

Uses.—Because of the severe griping which it produces, this preparation is rarely employed except in conjunction with other remedies. In cases of obstinate constipation it may be given with equal portions of fluidextract of cascara sagrada. It is also administered with the saline purgatives, but when so given carminatives should be added to prevent or diminish the griping. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM SERPENTARIÆ, *U. S.*—Fluidextract of Serpentaria.

Extrait liquide de serpentaire, Fr.; *Flüssiges Schlangenwurzelextrakt*, G.

Preparation.—Serpentaria, in No. 50 powder, 1000 Gm.; alcohol, water, each a sufficient quantity so make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the serpentaria is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C.(122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces should be moistened with about 7½ fluidounces of menstruum (alcohol 4 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve. The final volume of finished product should be made up to 24 fluidounces.

The virtues of serpentaria are well exhausted and properly preserved by this process. The fluidextract has a red-brown color and the peculiar odor and bitter taste of the drug.

Uses.—Fluidextract of serpentaria fully represents the virtues of the drug (which see). It is given internally in doses of from 15 to 30 minims (1–2 Cc.). As a local application it is said to be of value in ivy-poisoning.

FLUIDEXTRACTUM SPIGELIÆ, *U. S.*—Fluidextract of Spigelia.

Extrait liquide de spigélie, Fr.; *Flüssiges Spigelienextrakt*, G.

Preparation.—Spigelia, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of diluted alcohol and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the spigelia is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Originally, the fluidextract was saccharine, and in 1870 the sugar was replaced by glycerin. It was found, however, that it will keep unaltered in the form of a concentrated tincture, as by the present formula. It is a dark-brown liquid.

FLUIDEXTRACTUM SPIGELIÆ ET SENNÆ.—*Fluidextract of spigelia and senna*, E.; *Extrait liquide de spigélie et séné*, Fr.; *Flüssiges Spigelien- und Sennaextrakt*, G.—After 1860 this preparation was made by mixing fluidextract of spigelia 10 fluidounces with fluidextract of senna 6 fluidounces and oils of caraway and of anise each 20 minims. A more elegant and satisfactory preparation, however, is obtained, according

to Alonzo Robbins (1883), by preparing it from the drugs, as originally suggested by Procter (1848), omitting the alkali; the proportions are spigelia 60 Gm., senna 30 Gm., anise and caraway each 5 Gm.; the menstruum is diluted alcohol, and the yield is 100 Cc.

Uses.—The action of spigelia is well represented by the fluidextract; the latter may be employed for all conditions in which the former is recommended. The dose is from ½ to 2 fluidrachms (2–8 Cc.).

FLUIDEXTRACTUM STAPHISAGRIÆ, *U. S.*—Fluidextract of Staphisagria.

Fluidextract of stavesacre seed, E.; *Extrait liquide des semences de staphisaigre*, Fr.; *Flüssiges Stephanskörnerextrakt*, G.

Preparation.—Staphisagria, in No. 40 powder, 1000 Gm.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Mix 800 Cc. of alcohol with 200 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed slowly, gradually adding menstruum, using the same proportions of alcohol and water as before, until the staphisagria is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50 C. (122 F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered seed should be moistened with 10 fluidounces of a mixture of alcohol 4 volumes and water 1 volume, and the first 20 fluidounces of percolate set aside as reserve; the final volume of the fluidextract should measure 24 fluidounces.

Stavesacre seed contains from 20 to 30 per cent. of fixed oil, and if strong alcohol were used for extraction the oil would partly separate and become very troublesome. By the addition of water it is hoped to overcome this difficulty, as the oil is less liable to be taken up. The fluidextract has a decided green color, but no particular odor or taste except that of the alcoholic menstruum.

Uses.—This, in combination with ether and alcohol, is used to destroy lice. It is not given internally.

FLUIDEXTRACTUM STILLINGIÆ, *U. S.*—Fluidextract of Stillingia.

Extrait liquide de stillingie, Fr.; *Flüssiges Stillingiaextrakt*, G.

Preparation.—Stillingia, in No. 40 powder, 1000 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of diluted alcohol, and pack it firmly in a cylindrical percolator; then add sufficient diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the stillingia is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum, and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of stillingia will sometimes become gelatinous on standing, which difficulty may be overcome by the addition of sugar (about 10 or 12 per cent. of the weight of drug used); a somewhat stronger alcoholic menstruum (alcohol 3 volumes, water 1 volume) also seems to improve the preparation materially. It is of a dark red-brown color and has the bitterish, pungent taste of the root.

Uses.—The alterative properties of this preparation are equivalent to those of the drug (which see). The dose is from 15 to 30 minims (1–2 Cc.).

FLUIDEXTRACTUM STRAMONII, *U. S.*—Fluidextract of Stramonium.

Fluidextract of stramonium seed, U. S., 1890; *Extrait liquide des feuilles de stramoine*, Fr.; *Flüssiges Stechapfelblätterextrakt*, G.

Preparation.—Stramonium, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the stramonium is exhausted. Reserve the first 800 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid as directed below; from the results thus obtained ascertain, by calculation, the amount of mydriatic alkaloids in the remainder of the liquid, and add to this sufficient menstruum to make each 100 Cc. of the finished fluidextract contain 0.35 Gm. of the mydriatic alkaloids from stramonium.

Assay of Fluidextract of Stramonium.—The method to be employed is identical with that given under FLUIDEXTRACT OF BELLADONNA ROOT.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with about 10 fluidounces of the menstruum (alcohol 2 volumes, water 1 volume), and the first 20 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

Fluidextract of stramonium is of a deep green-brown color, and has the characteristic heavy odor of the drug. It should be borne in mind that stramonium seed are no longer recognized in the U. S. P., and that the present official fluidextract is made from the leaves of stramonium.

Uses.—Fluidextract of stramonium may be employed for all the conditions in which the drug is recommended. The dose is from 1 to 2 minims (0.05–0.10 Cc.).

FLUIDEXTRACTUM SUMBUL, *U. S.*—Fluidextract of Sumbul.

Fluidextract of muskroot, E.; *Extrait liquide de sumbul*, Fr.; *Flüssiges Sumbulwurzel-oder Moschuswurzelextrakt*, G.

Preparation.—Sumbul, in No. 30 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it moderately in a cylindrical percolator, then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the sumbul is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.

25 avoirdupois ounces of the powdered drug should be moistened with about 7½ fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of sumbul is one of the new preparations officially recognized in the Pharmacopœia. It is of a yellowish-brown color and has the peculiar musk-like odor of the root. Since the virtues of sumbul reside chiefly in the oil and an acid present, the menstruum directed appears desirable for complete exhaustion of the drug.

Uses.—The antispasmodic properties of the root are well represented by the fluidextract. The dose is from 15 to 45 minims (1–3 Cc.).

FLUIDEXTRACTUM TARAXACI, *U. S.*—Fluidextract of Taraxacum.

Extractum taraxaci liquidum—Liquid extract of taraxacum, Br.; *Fluidextract of dandelion*, E.; *Extrait liquide de pissenlit*, Fr.; *Flüssiges Löwenzahnextrakt*, G.

Preparation.—Taraxacum, in No. 30 powder, 1000 Gm.; solution of sodium hydroxide, 50 Cc.; diluted alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of diluted alcohol and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed slowly, gradually adding diluted alcohol, until the taraxacum is exhausted. Reserve the first 800 Cc. of the percolate; distil off the alcohol from the remainder by means of a water-bath and evaporate the residue to a soft extract; dissolve this in the reserved portion, add the solution of sodium hydroxide, and enough diluted alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the powdered drug should be moistened with about 7½ fluidounces of diluted alcohol, and the first 20 fluidounces of percolate set aside as reserve; after evaporation of the second percolate to a soft extract and solution in the reserve portion, 1¼ fluidounces of sodium hydroxide solution should be added, and the final volume of fluidextract made up to 24 fluidounces by addition of diluted alcohol.

The Br. P. directs that 20 ounces of taraxacum root, in No. 20 powder, be macerated for 48 hours in a closed vessel with 40 fluidounces of 60 per cent. alcohol. 10 fluidounces of liquid are then expressed and set aside, the residue being mixed with 40 fluidounces of water and again allowed to macerate for 48 hours. After expression, the aqueous liquid is evaporated to 10 fluidounces and mixed with the hydroalcoholic liquid previously expressed. If necessary sufficient water is added to bring the volume up to 20 fluidounces.

Fluidextract of taraxacum is of a reddish-brown color, and if made from true dandelion root has a bitterish-sweet taste. More decided bitterness would point to the probable adulteration with chicory. The addition of sodium hydroxide solution to the percolate, as directed in the present formula, is for the purpose of avoiding effervescence should the fluidextract be dispensed together with carbonates or bicarbonates, as taraxacum yields a slightly acid percolate with diluted alcohol.

Uses.—When prepared from the fresh root, the properties of the fluidextract equal those of the drug. The dose is from ½ to 1 fluidrachm (2–8 Cc.).

FLUIDEXTRACTUM TRITICI, *U. S.*—Fluidextract of Triticum.

Fluidextract of couch-grass, E.; *Extrait liquide de chiendent*, Fr.; *Flüssiges Quecken-extrakt*, G.

Preparation.—Triticum, finely cut, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Pack the triticum in a cylindrical tinned copper or tinned iron percolator, pour boiling water upon it and allow percolation to proceed, supplying boiling water as required, until the triticum is exhausted. Evaporate the percolate to 750 Cc., and, having added to it 250 Cc. of alcohol, mix well and set it aside for 48 hours. Then filter the liquid, and add to the filtrate sufficient of a mixture composed of 3 volumes of water and 1 volume of alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of finely cut couch-grass should be exhausted by percolation with boiling water, and the infusion evaporated to 18 fluidounces; after addition of 6 fluidounces of alcohol the mixture is set aside for 48 hours, filtered, and to the filtrate sufficient of a menstruum, composed of alcohol 1 volume and water 3 volumes, added to bring the final volume of the finished product up to 24 fluidounces.

The manipulation for preparing this fluidextract will be successful only if suitable provision be made to let the liquid pass from the percolator in drops, the drug being too coarse and unyielding to permit its packing like most of the other powders. We consider digestion preferable to percolation, since the drug is thus easily exhausted, and by shortening the process fermentation of the strongly saccharine liquid is prevented. For the reason stated the liquid should be rapidly concentrated. The fluidextract is of a brown color and has a sweet taste.

A solid extract of triticum was formerly official in the P. G. under the name *Extractum Graminis*, and is still recognized in the French Codex as *Extrait de Chiendent*. The latter preparation is directed to be made by exhausting the drug with cold distilled water by maceration, using two successive portions, mixing the expressed liquids, allowing the mixture to subside, decanting, and evaporating the clear liquid to the consistence of a soft extract.

Uses.—This is the best preparation of the drug to employ, as it is thought to represent more thoroughly than any other preparation the medicinal properties of the plant. The dose is from 2 to 4 fluidrachms (8–16 Cc.).

FLUIDEXTRACTUM UVÆ URSI, *U. S.*—Fluidextract of Uva Ursi.

Extrait liquide de busserole, Fr.; *Flüssiges Bärentraubenblätterextrakt*, G.

Preparation.—Uva ursi, in No. 30 powder, 1000 Gm.; glycerin, 300 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix the glycerin with 200 Cc. of alcohol and 500 Cc. of water, and, having moistened the powder with 400 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of 200 Cc. of alcohol to 500 Cc. of water, until the uva ursi is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient of the mixture of alcohol and water to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 10 fluidounces of a mixture composed of alcohol 4¾ fluidounces, water 12 fluidounces, and glycerin 7¼ fluidounces, subsequent percolation to be continued with a menstruum of alcohol 2 volumes, water 5 volumes; the first 22 fluidounces of percolate should be set aside as reserve, and the final volume of finished product made up to 24 fluidounces.

The large quantity of glycerin directed appears to us unnecessary; in fact, glycerin may be omitted entirely, since experience has shown that diluted alcohol completely exhausts the drug and yields a fluidextract which keeps well. We should prefer the latter menstruum for this preparation. The fluidextract is of a dark-brown color and possesses a bitter, astringent taste.

Uses.—The uses of fluidextract of uva ursi are fully described under the drug (which see). It may be administered in capsules, but is probably more efficient when administered largely diluted with water. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM VALERIANÆ, *U. S.*—Fluidextract of Valerian.

Extrait liquide de valériane, Fr.; *Flüssiges Baldrianextrakt*, G.

Preparation.—Valerian, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the valerian is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of the finished product should be made up to 24 fluidounces.

The present menstruum has been found to yield excellent results. The fluidextract is of a deep red-brown color, and has the characteristic odor and taste of valerian. Little loss of oil will occur if proper care is observed in the percolation and evaporation.

EXTRACTUM VALERIANÆ has been dismissed from most pharmacopœias. The French Codex directs it to be made with alcohol of specific gravity 1.914; the yield is 19 or 20 per cent. It may be readily prepared by concentrating the fluidextract at a moderate heat on a water-bath.

Uses.—Fluidextract of valerian is a very efficient preparation, and may be employed for the various conditions in which the drug is recommended. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM VERATRI, *U. S.*—Fluidextract of Veratrum.

Extractum veratri viridis fluidum, U. S. 1890—*Fluidextract of American veratrum*, E.; *Extrait liquide de vératre américain*, Fr.; *Flüssiges Grüngermerextrakt*, G.

Preparation.—Veratrum, in No. 60 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 300 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the veratrum viride is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50°C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum, and the first 22 fluidounces set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The resins and alkaloids are readily taken up and held in solution by the menstruum directed, and the fluidextract is therefore ten times as strong as the tincture of the same drug.

Uses.—The fluidextract is employed less frequently than the tincture; it is, however, a very efficient preparation. The dose is from 1 to 2 minims (0.05–0.10 Cc.).

FLUIDEXTRACTUM VIBURNI OPULI, *U. S.*—Fluidextract of Viburnum Opulus.

Fluidextract of cramp-bark, E.; *Flüssiges Schneeballrindenextrakt*, G.

Preparation.—Viburnum opulus, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 300 Cc. of the mixture, pack it moderately in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the viburnum is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum, and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of cramp-bark has a reddish-brown color, slight odor, and somewhat astringent taste.

Uses.—This preparation may be administered whenever viburnum opulus is indicated. The dose is from 15 to 60 minims (1–4 Cc.).

FLUIDEXTRACTUM VIBURNI PRUNIFOLII, *U. S.*—Fluidextract of Viburnum Prunifolium.

Fluidextract of blackhaw-bark, E.; *Extrait liquide de viburne*, Fr.; *Flüssiges Viburnumextrakt*, G.

Preparation.—Viburnum, in No. 40 powder, 1000 Gm.; alcohol, water, each a sufficient quantity to make 1000 Cc. Mix 600 Cc. of alcohol with 300 Cc. of water, and, having moistened the powder with 300 Cc. of menstruum, pack it moderately in a

cylindrical percolator; then add sufficient of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the viburnum is exhausted. Reserve the first 850 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient menstruum to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 7½ fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 21 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

The fluidextract is of a deep brown-red color and possesses the astringent and bitter taste of the bark.

Uses.—It is thought to represent the medicinal properties of the drug. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

FLUIDEXTRACTUM XANTHOXYLI, *U. S.*—Fluidextract of Xanthoxylum.

Fluidextract of prickly ash, E.; *Extrait liquide d'écorce de clavalier*, Fr.; *Flüssiges Zahnwehrindenextrakt*, G.

Preparation.—Xanthoxylum, in No. 40 powder, 1000 Gm.; alcohol, water, of each a sufficient quantity to make 1000 Cc. Mix 750 Cc. of alcohol with 250 Cc. of water, and, having moistened the powder with 250 Cc. of the mixture, pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the xanthoxylum is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 6 fluidounces of menstruum (alcohol 3 volumes, water 1 volume), and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Fluidextract of prickly ash is of a reddish-brown color, and possesses the acrid taste of the bark.

Uses.—It is probable that this preparation contains all the active constituents of xanthoxylum. Its dose is stated to be from ½ to 1 fluidounce (2–4 Cc.).

FLUIDEXTRACTUM ZINGIBERIS, *U. S.*—Fluidextract of Ginger.

Extrait liquide de gingembre, Fr.; *Flüssiges Ingwerextrakt*, G.

Preparation.—Ginger, in No. 50 powder, 1000 Gm.; alcohol, a sufficient quantity to make 1000 Cc. Moisten the powder with 250 Cc. of alcohol and pack it firmly in a cylindrical percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the ginger is exhausted. Reserve the first 900 Cc. of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add sufficient alcohol to make the fluidextract measure 1000 Cc.—U. S.

25 avoirdupois ounces of the drug should be moistened with about 6 fluidounces of menstruum (alcohol), and the first 22 fluidounces of percolate set aside as reserve; the final volume of finished product should be made up to 24 fluidounces.

Ginger is readily exhausted by alcohol; the brownish-red fluidextract is 5 times stronger than the tincture of ginger, and has the same sensible properties, but in a higher degree. It is used in preparing Syrupus Zingiberis.

Uses.—This preparation is less convenient than the oleoresin, but it represents the medicinal properties of the drug. The dose is from 5 to 20 minims (0.3–1.3 Cc.).

FŒNICULUM, *U. S.*—Fennel.

Fœniculi fructus, Br.; *Fructus fœniculi*, P. G.; *Semen fœniculi.—Fennel-fruit, Fennel-seed*, E.; *Fenchel*, G.; *Fenouil*, Fr.; *Hinojo*, Sp.; *Funcho*, Port.; *Finocchio*, It.

The dried, nearly ripe fruit of *Fœniculum vulgare* Miller (*Anethum F.* L.; *Meum F.* Spreng.: *F. Capillaceum* Gilib.; *F. dulce* DC.; *F. Fœniculum* (L.) Karst.; *F. officinale* All.—Fam. *Umbelliferæ*).

Fennel is official in all pharmacopœias, which differ widely as to the botanical name employed and as to the varieties admitted. *F. Fœniculum* (L.) Karst. is the correct name.

Origin.—From a tall, coarse herb, annual to perennial according to the climate, native of southwestern Asia and southern Europe. It is frequently seen wild in the United States. It has a somewhat branched, light-green, glaucous, furrowed stem, very large leaves with coarsely sheathing petioles and decompound blades, the divisions narrowly linear and elongated. The large compound umbels of yellow flowers terminate the stem and branches and are entirely non-involucrate. All parts of the plant have an agreeable odor and an aromatic, sweetish taste. The cultivated forms of the plant vary so greatly that there is considerable diversity of opinion among botanists as to their being distinct species. The fruit is obtained from cultivated plants, mostly in Germany, Russia, and France, though the plant is cultivated in almost all parts of the world except where very cold, and various other countries than those named contribute more or less to commerce. Saxon fennel, the largest variety, is usually preferred.

Fig. 182.

a *b*

Fœniculum: *a*, fruit (× 3); *b*, transverse section (× 8).

Description.—Of 2 separate or united carpels, each 0.6 to 1 Cm. (¼ to ⅖ In.) long, about one-third as broad and one-sixth as thick, oblong or a little narrowed at the summit, more or less curved, bearing 5 very prominent and stout light-colored ribs upon the back, otherwise smooth, yellowish- or brownish-green; pericarp containing an oil-tube between each two ribs and 2 upon the flat side; odor pleasantly aromatic; taste sweet and pleasantly aromatic.

German, French, and Indian fennels are all about of the dimensions given above; Russian and Japanese, only about half as large. Bitter fennel, from wild plants, and mostly French, is one of the smallest. The Japanese is reported to have a distinctive odor closely approaching that of anise, than which it is but little larger. The Indian fennel plant is classed as a distinct species, *F. panmorium* DC. Roman fennel is a very large and sweet, greenish variety, referred to *F. dulce*, regarded by some as a distinct species.

Exhausted fennel, which yields a yellowish instead of a dark-brown infusion, is largely ground with the genuine, and it is reported that it is often tinged with chrome-yellow and thus sold entire. Moistening with alcohol and rubbing will detach this color.

Constituents.—The important constituent of fennel is its volatile oil, the amount of which ranges from 2 to 5 per cent., and which has a peculiar sweet taste, usually more or less camphoraceous. With this are about 12 per cent. of fixed oil, sugar, and ordinary plant-constituents. Umney found the Saxon, Russian, and Galician fruits to yield about 4.5 per cent., the French and Japanese, a little more than 2 per cent. of this oil. The ash is usually from 8 to 10 per cent., occasionally as much as 12 per cent.

Action and Uses.—Fennel is diaphoretic, aromatic, and carminative. It is sometimes employed for the purpose of expelling flatus, and a hot infusion, 3 drachms (12 Gm.) to a pint (480 Cc.) of water, is occasionally given to increase the lacteal secretion, to produce free sweating, and to establish the menstrual flow. Fennel may also be combined with purgatives for the purpose of decreasing their griping effect. The dose of the bruised or powdered fruit is from 10 to 30 grains (0.6–2 Gm.).

Allied Product.—*Fennel root* is somewhat employed in Europe. It is 15 to 25 Cm. (6 to 10 In.) long, above nearly 25 Mm. (1 In.) thick, several-headed, cylindrical, little branched, but beset with numerous thin and wrinkled radicles. The root is externally light-brown, annulate, and longitudinally wrinkled, internally white; the bark thick, fleshy, with several circles of brown resin-cells, and the meditullium yellowish and radially striate. It has an aromatic odor and a sweet fennel-like taste, and contains a little volatile oil and considerable sugar and starch.

FŒNUM GRÆCUM.—Fenugreek.

Semen fœnugræci, P. G.; *Bockshornsamen*, G.; *Fenugrec, Sencgrain*, Fr.; *Alholva*, Sp. The dried ripe seeds of *Trigonella Fœnum-græcum* L. (Fam. *Leguminosæ*).

Origin.—From a small herb, native of southwestern Asia, and extensively cultivated in tropical and subtropical Asia and Africa, and somewhat naturalized there and in southern Europe. The seeds of other species of the genus have a similar composition and properties.

Fig. 183.

Fenugreek (×3).

Description.—About 3 Mm. ($\frac{1}{8}$ In.) long and broad, and 2 Mm. ($\frac{1}{12}$ In.) thick, obliquely rhomboidal, each surface bearing a deep groove running diagonally nearly across; brownish-yellow, smooth, somewhat shining; hard and heavy; odor strong, peculiar, not agreeable; taste mucilaginous, bitterish, bean-like and peculiar. Structure exalbuminous, the embryo yellowish, the caulicle large, strongly bent against the edges of the cotyledons; a peculiar horn-like tissue, probably the tegmen, though regarded by some as perisperm, surrounds the embryo.

Powdered Fenugreek is very apt to be adulterated with starchy matters.

Constituents.—As a nutrient, the seed is essentially albuminous, about one-fourth of its weight being of such composition. There is about 6 per cent. of fixed oil. The integuments contain a little tannin and a large amount (about 28 per cent.) of gum. The specific constituents are *trigonelline*, 0.13 per cent., with about 0.05 per cent. of choline, a small amount of an amaroid, and a peculiar hydrocarbon, imparting the odor. Trigonelline ($C_7H_7NO_2$) is isomeric with pyridine-betaine. The odorous principle is derived from a *manno-galactane*, very similar to that of lucerne, which, on hydrolysis, yields mannose and galactose. The manno-galactane can be removed by macerating in excess of solution of lead acetate, removing the excess by oxalic acid, and precipitating from the aqueous filtrate by alcohol.

Action and Uses.—Fenugreek possesses emollient properties, but is no longer employed in internal medicine. It is used in the preparation of emollient poultices, demulcent lotions, and ointments. The oil is sometimes applied in the treatment of burns.

FRANCISCEA.—Brunfelsia; Manaca.

Manacán, Geratacáca, Camgámba, Mercurio Vegetal, Braz.

The dried root of *Brunfelsia Hopeana* Benth. (*Franciscea uniflora* Pohl.—Fam. *Solanaceæ*).

The stem is similarly used, but is held to be very inferior to the root. The flowers are said to be used by the natives as an application to indolent ulcers.

Origin and Description.—The Manaca plant is a large shrub, growing in lowlands along streams in Brazil and bearing a handsome purplish, infundibular-bell-shaped flower. The root occurs in short pieces about 6 to 25 Mm. ($\frac{1}{4}$ to 1 In.) thick, externally dark-brown or rust-brown, and often thinly scaly. The bark is thin and adheres tightly to the hard, tough, reddish-yellow wood. The stem contains a thin pith, the root none. Manaca is inodorous and has a disagreeably bitter taste.

Constituents.—We are uncertain as to the constituents of this drug, since the identity of the materials which have been examined was not fixed, three different Manacas being in use. It is probable, however, that the "Red Manaca," the composition of which is here considered, is that under discussion.

Red Manaca contains fat, resin, 11.25 per cent. of starch, the alkaloid *manacine*, and a fluorescent compound. This latter is probably identical with gelsemic acid, is readily soluble in alcohol and chloroform, less so in water and ether, is not a glucoside but reduces Fehling's Solution. Its aqueous solution is acid, and is yellow by transmitted light, blue by reflected light, the fluorescence being increased by ammonia. It resembles a similar constituent of *Fabiana*. *Manacine* is amorphous, slightly bitter, weakly basic, soluble in water, alcohol, and methyl alcohol, and easily decomposed in solution. It is precipitated by alkaloidal reagents, but not by alkalies. The alkaloid *francisceine* is probably the same as that just described. Brandl (1895) split it into *manaceine* and a fluorescent resinous substance identical with æsculetin. Some investigators have failed to find an alkaloid.

Action and Uses.—Manaca probably acts as a depressant to the motor centers of the spinal cord. When given in full dose, it occasions respiratory difficulty, profuse sweating, depression, nausea and vomiting, an increased urinary flow, and free purgation. In overdose it is an acrid depressing poison. In medicinal dose it has been employed in the treatment of chronic muscular rheumatism, and has been recommended as a substitute for mercury in the treatment of syphilis. The fluid extract may be given in doses of from 10 to 40 minims (0.6–2.6 Cc.), 3 times daily.

FRANGULA, *U. S.*—Frangula.

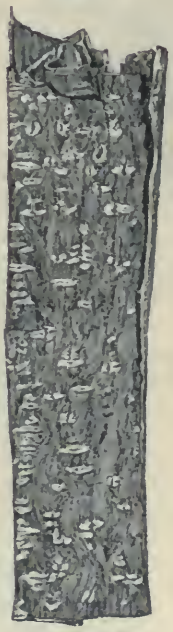
Rhamni frangulæ cortex, Br.; *Cortex frangulæ*, P. G.—*Cortex Alni Nigræ*, Russ.—*Buckthorn, Alder buckthorn*, E.; *Faulbaumrinde*, G.; *Écorce de Bourdaine* (*Bourgene*), Fr.; *Corteccia de Frangula*, It.; *Amiero Negro*, Port.

The dried bark of *Rhamnus Frangula* L. (*Frangula vulgaris* Reichb.; *F. Alnus* Mill.—Fam. *Rhamnaceæ*), collected at least one year before being used.

Frangula is official in nearly all pharmacopœias. From the last edition of the Br. P. it has been dropped in favor of *R. Purshiana*.

Origin.—From a rather slender large shrub growing throughout Europe, western Asia, and northern Africa. Introduced by Michaux to his ancient Botanical Garden at New Durham, N. J., it has escaped and is naturalized in a few places near New York City. For medicinal purposes, the bark is collected in the spring, from the younger trunks and large branches. Large quantities also result as a bye-product from the peeling of the wood for the making of gunpowder carbon. The sharply purgative properties of the fresh bark are ameliorated by the peasants by keeping it a year before using, as our definition requires.

Fig. 184.



Frangula.

Description.—In quills of variable length, rarely exceeding 2.5 Cm. (1 In.) in diameter, and frequently flattened or crushed, the bark 1 Mm. ($\frac{1}{25}$ In.) or less in thickness; externally from dark-gray to purple-black, usually with transversely elongated, rarely circular white spots and occasionally with ashy patches of lichen-growth, irregularly wrinkled and often warty-roughened; internally nearly smooth, minutely striate, dark-yellow to brown; fracture short and deep-purple in the outer, fibrous and yellow in the inner layer; odor distinct, peculiar; taste somewhat aromatic, sweetish and bitter; tingeing the saliva yellow when chewed.

When moistened with lime water, it acquires a red color. With cold water it yields a yellow, and with hot water a brown, infusion, which is colored dark-brown, but not precipitated, by ferric chloride.

The powder exhibits an absence of stone-cells, which distinguishes it from Cascara Sagrada. The official bark is to be distinguished from that recently collected by its relative weakness and less disagreeableness of odor and taste, and by the dark color of the inner surface. When first collected, this is light-yellow, but very quickly turns to a medium or deep yellow, afterward becoming darker gradually. At the end of a year most of the quills should show a brown inner surface, this becoming blackish-brown after long keeping. Dieterich believes that the same effect as that of aging (the destruction of the irritating and nauseating ferment) can be secured by heating, since he maintained the bark in a temperature of 37.7° C. (100° F.) for 48 hours without decreasing the amount of the glucosides.

Constituents.—The most important constituent is *frangulin* or *rhamnoxanthin* ($C_{21}H_{21}O_9$), which occurs in odorless and tasteless, silky-lustrous, lemon-yellow crystals; by sublimation it forms yellow needles. It is soluble in hot fixed oils, benzin, turpentine, 160 parts of warm 80 per cent. alcohol, and with a bright-purple color in alkalies; it is insoluble in water, and nearly insoluble in cold alcohol and ether. It dyes cotton, wool, or silk. Boiled with dilute acids it yields *rhamnose* ($C_6H_{12}O_5$) or *rhamnodulcite* ($C_{21}H_{20}O_9$) (Schwabe), and *emodin* ($C_{15}H_{10}O_5$). The bark also contains yellow resinous matter, tannin, an amorphous bitter principle, and an odorous volatile principle. The ash amounts to 5 or 6 per cent. When fresh, the bark contains a nauseating hydrolytic ferment, which is destroyed by heat or long keeping. Kubly's *avornin* is impure fran-

gulin, and his *frangulic acid* is *pseudofrangulin* (Aweng), which hydrolyzes to *pseudoemodin*, both being somewhat aperient.

Pharmaceutical Preparations.—Elixir of Frangula, N. F.; Fluidextract of Frangula, U. S. P.

Action and Uses.—Frangula in the fresh state is exceedingly acrid, and when taken internally produces gastro-intestinal pain, with nausea and vomiting and excessive purgation. In the dried state it loses its acridity considerably, and is then said to resemble senna and rhubarb in its action. It is employed quite extensively in Great Britain and Germany in the treatment of habitual constipation, but is rarely used in the United States for this purpose. It may be administered in the dose of 20 minims (1.3 Cc.) of the fluid extract twice daily. A decoction (1 ounce to the pint) may be given in the dose of 4 drachms (16 Cc.), in the treatment of dropsy, and may also be locally applied as a cure for itch.

FRAXINUS.—Ash.

Esche, G.; *Frêne*, Fr.; *Fresco*, Sp.

The dried bark of several species of *Fraxinus* L. (Fam. *Oleaceæ*), especially of *F. Americana* L. (*F. acuminata* Lam.; *F. alba* Marsh.; *F. epiptera* Mx.; *F. Caroliniana* Wang.), the *White* or *American ash* or *Cane ash*, and *F. excelsior* L., the *European ash*.

The European species is often cultivated as a shade-tree in the United States. The American white ash grows almost throughout eastern and central North America. It attains a height of 18 to 24 M. (60 to 80 Ft.), has a durable, tough wood, 7 to 9 ovate-oblong, acuminate leaflets, and a terete fruit extended above into a spatulate-linear wing. The bark, which has been employed, is collected from the trunk and the root, the latter being preferred.

Description.—Ash bark is 3 to 6 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ In.) in thickness, usually freed from the corky layer, whitish or yellowish, sometimes brownish, frequently with ridges of a warty cork adhering, and upon the inner surface yellowish and smooth; it breaks with a very fibrous fracture, and has a slight aromatic odor and a bitter and somewhat acrid taste.

European ash bark occurs in quills which are gray or greenish-gray externally, with numerous small gray or brownish-white warts, the inner surface yellowish or yellowish-brown and nearly smooth; fracture smooth, fibrous in the inner layer; odor slight; taste bitter and astringent.

Constituents.—European ash bark contains the bitter glucoside *fraxin* ($C_{16}H_{18}O_{10}$), the bitter substance *fraxetin* ($C_{10}H_8O_5$), tannin, quercitrin, mannit, a little volatile oil, gum, malic acid free and combined with calcium. The American contains tannin, resin, and a little volatile oil, and perhaps an alkaloid.

Action and Uses.—Ash bark has been employed as a bitter tonic and astringent, and is said to be valuable as an antiperiodic. Infusions of the leaves are said to be diuretic, diaphoretic, and purgative. They have been employed in the treatment of gout and rheumatism. The bark has been used in the treatment of intermittent fevers, but at present is rarely employed. An infusion of the leaves, 1 ounce to the pint (30 Gm. to 480 Cc.), may be given during the 24 hours.

Allied Species.—Southward, especially in Mexico, the bark and leaves of *F. nigra* Marsh. (*F. sambucifolia* Lam.), the *Black*, *Swamp*, *Water*, *Hoop*, or *Basket ash*, are similarly employed. In Mexico, also, the bark and leaves of *F. lanceolata* Borck. (*F. viridis* Mx.), the *Green* or *Blue ash*, are employed as a bitter tonic, and the root as a diuretic. The fruits of the different species of ash are regarded as somewhat more active than the bark and leaves.

Oleaceæ.—This family, to which *Fraxinus* belongs, comprises some 20 genera and about 350 species. Besides the Olive, its most important product, and Manna, it is notable for some highly ornamental plants, including the Jasmines, the Lilacs, and the Fringe-tree. Besides the species of ash above considered, the following medicinal species are worthy of note:

Chionanthus is the bark of the root of *C. Virginica* L., the *Fringe-tree*, *White fringe*, *Gray beard* or *Old man's beard*, *Shavings-tree*, or *Flowering ash*, of the southeastern United States. It has also been called *Poison ash*, apparently without reason. The bark is intensely bitter, and contributes its bitterness to both alcohol and water. The bitter principle has not been studied. The drug has many uses among the eclectics and homœopaths, especially as a depurant in hepatic and syphilitic disorders. It may be used in doses of from 15 to 30 grains (1–2 Gm.).

Ligustrum is the bark and leaves of the European *L. vulgare* L., the well-known privet, so largely used for hedges. The drug contains the crystalline tasteless glucoside *syringin*, so

called because first found in Syringa; also a bitter resin. *Syringopikrin*, another constituent of Syringa, is said also to occur in this drug. Ligustrum has been used as an abdominal astringent, especially in ulcerated conditions of the stomach and intestines. Its fruits are poisonous.

Syringa is the leaves of *S. vulgaris* L., the common garden Lilac, native of Europe. Its composition appears almost identical with that of Ligustrum, and its uses are similar.

The roots of several species of *Jasminum* L. have had various ill-defined uses in medicine. One of them, at one time known as "Gelseminum," led to a serious confusion concerning the name *Gelsemium*.

The genus *Linociera* yields a number of edible tropical fruits.

FUCUS VESICULOSUS.—Bladder-wrack.

Quercus marina, Sea-wrack, Lady-wrack, Kelp-ware, Black-tang, Cut-weed, Sea-oak, E.; *Varech vésiculeux*, Fr. Cod.; *Blasentang, Höckertang, Seetang, Seereiche, Meereiche*, G.; *Encina de mar, Fuco avejigado*, Sp.

The entire dried plant, *Fucus vesiculosus* L. (Fam. *Fucaceæ*), a coarse, light-yellow or brownish-green sea-weed, growing in the greatest abundance on submerged rocks along the northern coasts of both the Atlantic and Pacific. It is collected and dried upon the beach, care being taken to turn it frequently, to avoid the development of a putrid odor. The thallus sometimes reaches a length of 3 or 4 feet, but the drug is almost always in shorter pieces.

FIG. 185.

Fucus vesiculosus: fruiting branch (Nat.).

Description.—The size and form of thallus and air-vesicles are shown in Fig. 182. It forms a much-wrinkled mass, blackish or with more or less of a whitish efflorescence or incrustation. It has a marine odor and a mucilaginous and saline taste. Occasionally, from some unexplained cause, it is very astringent.

Constituents.—Fucus contains a very little volatile oil, to which its odor is but partly due. There is considerable mucilaginous matter, the nature of which has not been investigated, associated with a peculiar cellulose. The bitterness is probably due to a specific constituent. Its important constituents are inorganic, being iodine and bromine compounds of sodium and potassium, contained in the ash, which is from 2.5 to 4 per cent. Its charcoal, which is similarly used, is called *Æthiops vegetabilis*.

Action and Uses.—Bladder-wrack is not largely employed in medicine at the present time. It probably depends for its activity upon the iodine and bromine present. The bruised plant, and also the mucus found in the vesicles, have been locally applied to enlarged glands. Internally a decoction (4 drachms to the pint) (16 Gm.–480 Cc.) is said to have been useful in the treatment of obesity, and a charcoal prepared from the plant has been given in the treatment of goiter.

The decoction may be given in doses of 2 fluid-ounces (60 Cc.), 3 times daily. An alcoholic extract may be given in doses of 10 grains (0.60 Gm.) daily, and gradually increased.

Allied Species.—FUCUS NODOSUS L. (*Fucodium nodosum* Agardh) is about 1.2 to 1.8 M. (4 to 6 Ft.) long, and has a narrower frond or thallus without midrib, and with single vesicles, which are ovate or oblong, and usually large.

FUCUS SERRATUS L. has a veined and serrate frond, without vesicles.

FUCUS SILIQUOSUS L. (*Cystoseira s.* Agardh; *Halidrys s.* Lyngbye).—The frond is very narrow, 0.6 to 1.2 M. (2 to 4 Ft.) long, with short branches, articulated vesicles of a pod-

like appearance, and lanceolate flattened tubercular fruitification. This and the preceding species are permitted by the French Codex to be employed in the place of *F. vesiculosus.*

Fucus natans L. (*Sargassum bacciferum* Agardh) is the *Gulf-weed* of the Atlantic Ocean, and is often found in immense masses floating in the sea. The frond is terete, and has linear and serrate branches and globular aculeate and stipitate vesicles of the size of a pea.

The fronds of various species of *Laminaria* are similarly used.

FUNGI.

This great division of flowerless plants, distinguished by the absence of chlorophyll from their tissues, is, with the exception of Ergota, of slight importance in medicine. If, as in accordance with some classifications, the bacteria be included, the fungi become of great economic importance. The useful and injurious relations of bacteria to man, through their direct effects upon his body, or indirectly through their effects upon those vegetable and animal substances which contribute to its support and comfort, cannot be considered in this article. Although these relations are frequently medicinal or toxicological, their history must be sought in works upon pathology, or under special titles (see Antitoxin).

The medicinal relations of the Fungi have for the most part been considered under the titles Agaricus, Taka-diastase, Ergota, and Cerevisiæ. It may be added that *Lycoperdon Bovista* L. (*L. giganteum* Batsch ; *Bovista g.* Nees), the *Giant puff-ball, Vesse-loup* (Fr.), *Bovist* (G.), was formerly known as "Fungus Chirurgorum," and was used for arresting hemorrhages (see Agaricus). *Elaphomyces granulatus* Fries (*Lycoperdon cervinum* L.), the *Hart's truffle*, or *Puff-ball, Truffe de cerf* (Fr.), *Hirschbrunst* (G.), a brown, warty species, about as large as a walnut and purplish-brown internally, was used for its supposed stimulant properties.

Lycoperdon, Puff-ball, Tuckahoe or *Indian bread,* is the fungus *Lycoperdon solidum* Gronovius (*Pachyma Cocos* Fries). The botanical names assigned to it have little value, since its life-history is so poorly known that it has not yet been classified. It is found attached to the roots of coniferous trees in the southern United States. It is said to grow in China also, and to be there known as *Fuh-ling.* It is irregularly globular or oval, 30 Cm. (1 Ft.) or less in diameter, and sometimes weighs several pounds. The outer surface is ashy-black and rugose, the inner tissue whitish and firm, though somewhat spongy and usually somewhat mealy, and of an irregular fracture. It is odorless and nearly tasteless, and is said, when cooked, to have been an important article of food among the aborigines. It consists chiefly of cellulose and pectose, in exceedingly variable ratio, with a little gum and glucose and a very little albuminoid.

The principal object of the present article is the consideration of the following poisonous fungi, which are often mistaken for edible species :

Of the larger Fungi, the edible species vastly outnumber the poisonous ones, but comparatively few of them are used—very few of them generally so. Most of those used are more or less resembled by poisonous species, and the similarity is in some cases so great that accidental poisoning is common. Although each such case of similarity should be studied as to the individual distinctions, yet the formulation of general rules for the rejection of all poisonous species has been always regarded, and with the best of reason, as of paramount importance. The most important of these general rules is that no one should collect any fungus for food purposes unless he shall have previously become thoroughly familiar with its identification. The following general rules have been formulated by Farlow : (1) Avoid Fungi when in the button-stage, and after the flesh has begun to decay, even if slightly ; (2) avoid those with a swollen base which is surrounded by a sac-like envelope, especially if the gills are white ; (3) avoid those having a milky juice unless such juice be reddish ; (4) avoid those with a spider-web or flocculent ring hanging to the upper part of the stalk ; (5) avoid those in which the pileus is thin in proportion to the gills and in which the gills are nearly all of equal length, particularly if the pileus be brightly colored ; (6) avoid those having a tubular or hollow stem, and of which the flesh changes color when cut or in which the mouths are reddish (other tubular-stemmed forms should be treated with caution).

The phraseology employed in the above rules is explained in the following individual account of the more important edible and poisonous species. The most largely consumed fungus is undoubtedly *Agaricus campestris* L., the common mushroom. Its life-history is in a general way typical of most of the other species here considered. The edible body is known as the *thallus,* and represents a stage of development distinct from that of the *mycelium,* the filamentous underground growth from which the thallus develops. The thallus makes its appearance as a globular mass, the "button-stage" referred to above, borne upon a short stem, as yet not visible. In this condition its distinctive characters are not apparent, and a poisonous species may easily be mistaken for it. The stem now elongates, and from it separates the lower edge of the ball or button. This edge is then elevated and carried outward until the ball becomes converted into an umbrella-shaped crown, the *pileus.* The

upper surface of the latter is now brownish-white, somewhat roughish, and a thickish, soft but somewhat tough skin can easily be peeled off from it. The pileus is quite thick, and its edge especially presents a thick aspect. The inferior surface is occupied by blade-like gills or *lamellæ*, which are pinkish or pinkish-brown, do not quite reach to the stem, and are of different lengths. The stem is solid, but its center is occupied by a sort of pithy substance. When still young, a thin membrane projects shortly from the stem at the point where the edge of the pileus separated from it, but this nearly or quite disappears afterward. Although younger mushrooms are preferred by most persons, the stage above described is that in which it can be collected without much fear of a mistake. It has no acid or biting taste in the raw condition. Later, the pileus enlarges, often to a breadth of 6 inches or more; the lamellæ become brown, then black, being loaded with ripe spores; and finally the whole softens and breaks down. In these later stages, decomposition may render even wholesome species dangerous, from ptomaine-poisoning. The poisonous fungi most resembling the mushroom

FIG. 186.

Amanita phalloides (Nat.) (after Atkinson).

are the *Amanitas*. These possess an organ not found upon the mushroom, but common to many other fungi, the *volva*. This is originally a covering to the unopened pileus. With the growth of the latter, the volva becomes ruptured, but commonly persists as a cup or tube surrounding the base of the stem, its margin entire, toothed, or even divided up into a ragged circle of scales; or, part or all of the volva may persist in the form of scales upon the top of the pileus. Although one species of *Amanita*, and various other fungi possessing a volva, are edible, yet the safest plan for those not familiar with them is to avoid all species possessing this organ. The Amanitas may also be distinguished from the mushrooms by their white lamellæ or gills and the relatively thin edge of the pileus. The poisonous Amanitas are not very liable to be mistaken for the mushroom, since the top of the pileus is usually colored, from yellow through shades of orange to red, or occasionally olive-brown. *A. phalloides* is, however, frequently white, in which case its other characters must be depended upon for recognition. This species is commonly called *Death-cup*, and is the most fatally poisonous of all Fungi. Its volva is partly a ragged-edged, basal cup, partly in scales upon the top of the

pileus, one or the other position predominating in different cases. It has a well-developed, partly drooping, white veil. *A. muscaria* (L.) Pers. (*Agaricus muscarius* L.), the *Fungus muscarius*, *Fly-agaric*, *Fly-fungus*, *Flybane* or *Bug-agaric*, *Agaric mouche* (Fr.), *Fliegenschwann* (G.), most commonly found growing in pine forests, is similar. Its upper surface is usually more brightly colored, the volva mostly in the form of scales upon the top of the pileus. Other poisonous European species of this genus are *A. panterina* and *A. verna*, the latter regarded by some as a variety of *A. phalloides*. The constituents of these Amanitas are considered below. Although the mushroom is thus pretty readily distinguished from the poisonous Amanitas, the same is not true of a fungus which is very largely consumed in southern Europe, namely, the *Amanita Cæsarea* ("Cæsar's mushroom"). So closely related to the above poisonous species, it shares their general appearance, and it is in seeking for this that most of the fatal mistakes are made. It is for this reason that most of the persons poisoned in the United States are foreigners, who have brought their knowledge of edible and poisonous species with them to this country. *P. Cæsaria* does, however, grow with some freedom

FIG. 187.

Amanita muscaria (Nat.) (after Atkinson).

Common mushroom (Nat.) (after Atkinson).

in the southern United States. Its stem, veil, and lamellæ are yellow, and it has a white volva in the form of a cup.

The Lepiotæ, or *Parasol fungi*, are edible and closely related to the Amanitas. They are hollow-stemmed and have no volva. One, with green spores, is somewhat poisonous. That most eaten is *L. procera*, with a brown pileus. *L. naucinoides* is white and more closely resembles *A. phalloides*.

A great many of the puff-balls (*Calvatia*) are eaten when in their early condition of a solid ball of cheesy texture, especially the large one *C. Bovista*. There is nothing of a poisonous character likely to be mistaken for them, except perhaps some of the *Stinking fungi*, too quickly known by their offensive odor. The same statement will apply to the subterranean truffle, collected in Europe, as well as the largely eaten *Morchellas* and *Gyromitras*. The latter, as well as the puff-balls, are apt to develop poisonous properties when old, even before decomposition sets in, so that they should be eaten only before the development of the spores. In many cases, the poisonous constituent is *helvellic acid*. Partial boiling, followed by rejection of this water and washing, is a safe procedure. The common puff-ball, when cooked, is said to have been an article of diet among the North American Indians. The smoke from the burning plant has been employed in the country for the purpose of stupefying bees in order that their honey may be collected without difficulty. It was formerly thought to contain a narcotic principle, but it has been determined that the stupefying effect of the smoke is due to the presence of carbon dioxide. If inhaled in large amount, it causes anæsthesia, and excessive quantities cause death by respiratory failure. A 25 per cent. tincture has been recommended in 1 drachm (4 Cc.) doses in the treatment of nervous affections, but the drug is of little importance in internal medicine.

Of the numerous other edible species, few are very generally consumed, and space for their further consideration is wanting. Some of them are resembled by poisonous species,

but the latter commonly have either an acrid, peppery, or biting taste when raw, or a vile odor.

Poisonous Constituents.—Kobert classifies the poisonous principles in Fungi into: (1) the acids—*e. g.*, helvellic acid; (2) alkaloids or alkaloid-like substances, as muscarine and neurine; (3) albuminoid or albuminoid-like compounds, as the enzymes, and phallin and other toxalbumins. From a pharmacopathological standpoint, they may be (excepting Ergot), divided into: (1) those acting purely upon the nerves, as muscarine and fungus-atropine; (2) those that produce local irritation, as various species of *Lactarius* and *Russula;* (3) those acting primarily upon the blood, as helvellic acid and phallin. The most important constituents are *muscarine,* especially in *Amanita muscaria,* and *phallin,* especially in *A. phalloides.* Muscarine ($C_5H_{15}NO_3$) is an alkaloid which is colorless, inodorous, crystalline, very deliquescent, insoluble in ether, sparingly soluble in chloroform, strongly basic, and yielding deliquescent salts which are precipitated by mercuric chloride, auric chloride, and potassio-mercuric iodide. Phallin is much less known, in all ways, than muscarine. It appears to be an albuminoid substance, related to serpent-venom and to the poisonous constituents of ABRUS, but differing from them in its greater activity when absorbed through the stomach. It is coagulated by heat, and is soluble in a solution of common salt. "Amanitine" is now known to be identical with choline. Kobert believes that *A. muscaria* contains another alkaloid antagonistic to muscarine, which he has called *pilzatropine.*

The action of *Amanita muscaria* depends principally upon its alkaloid muscarine. It prolongs the diastolic period of the heart, and large quantities may produce diastolic arrest. Upon the vasomotor system and the respiratory center it acts as a decided depressant, and its action upon the abdominal contents is also quite marked; peristaltic action at first being held in abeyance, and secondarily being greatly increased. Muscarine has been employed as a remedy for epilepsy, but is probably of little value. A 1 per cent. solution of an alcoholic extract has also been recommended in doses of from 5 to 15 minims (0.30–1 Cc.) in the treatment of the night-sweats of phthisis, and is said by those who have employed it most to be of some value. When poisonous doses have been taken, the symptoms usually make their appearance several hours after ingestion, and consist of respiratory and circulatory depression, nausea and vomiting, lacrymation, ptyalism, and at times great muscular depression. The body becomes covered with a cold, clammy sweat, the pulse becomes rapid and thready, and the patient passes into collapse. The condition should be met by the prompt administration by the hypodermic needle of large doses of atropine, which is the physiological antagonist, by the application of external heat, and by the early use of the stomach-tube or emetics. Purgatives such as castor oil should be freely given as early as possible.

The symptoms produced by the accidental ingestion of *Amanita phalloides* are usually delayed for the greater part of twenty-four hours, and consist of great respiratory and circulatory depression followed by collapse. The body becomes covered with a cold, clammy sweat, severe headache is present, and an active delirium sometimes occurs. Suppression of urine, albuminuria, hæmoglobinuria, or jaundice may occur. The temperature is frequently increased and the pulse is running and thready. After death the internal viscera are found to be in a state of fatty degeneration. The treatment consists in the administration of stimulants as indicated, and the emptying of the alimentary canal by means of emetics and purges. Atropine is to be freely used as an antidote.

G.

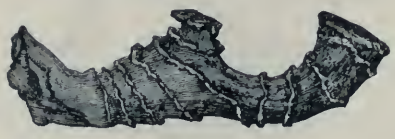
GALANGA.—Galangal.

Chinese ginger, E.; *Rhizoma (Radix) galangæ (minoris)*, P. G.; *Galgant*, G.; *Galanga*, Fr., Sp.

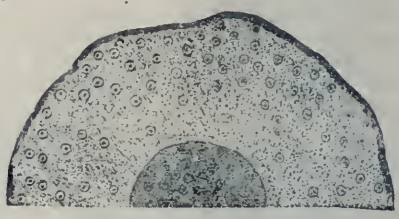
The dried rhizome of *Alpinia officinarum* Hance (Fam. *Zingiberaceæ*).

Origin.—From a perennial flag-like herb, bearing terminal racemes of white, red-veined flowers, native and somewhat cultivated in southeastern China.

FIG. 188.



Galanga.



Galanga: transverse section (× 3).

Description.—In sections, mostly short-branched, about 5 to 7 Cm. (2 to 3 In.) long and 0.5 to 2 Cm. ($\frac{1}{5}$ to $\frac{4}{5}$ In.) thick, terete, the joints somewhat thickened toward their summits; externally bright- or reddish-rust-brown, lightly wrinkled, slenderly annulate with the leaf-vestiges; internally pinkish or grayish-brown, quickly turning rust-brown after exposure; fracture tough, somewhat fibrous; transverse section exhibiting a dark endoderm at about one-third of the radial distance from the center, the oil-cells and wood-bundles scattered, the latter more numerous within the endodermis; odor and taste agreeably aromatic and pungent, ginger-like.

Constituents.—Galangal contains about 0.5 per cent. of pale- or brownish-yellow volatile oil, with a camphoraceous odor due to a large proportion of cineol, a soft acrid and pungent resin, gum, bassorin, 23 per cent. of starch, fixed oil, and 3 yellow crystalline principles, kaempferid, galangin, and alpinin ($C_{17}H_{12}O_6$). Kaempferid or "campheride" ($C_{16}H_{12}O_6$) is almost insoluble in water and alcohol, and with nitric acid forms anisic acid, oxalic acid, and other products. *Galangin* ($C_{15}H_{10}O_5$) is soluble in 68 parts of 90 per cent. alcohol and in 34 parts of absolute alcohol, and, oxidized by nitric acid, yields benzoic and oxalic acids. *Galangol* is an active pungent principle separated by Thresh.

The powder, except in color, which is rust-brown, quite closely resembles that of ginger. More fibers occur in it, and its starch-grains, much like those of ginger, average not more than half their size.

Action and Uses.—Galangal may be employed as a stimulant aromatic and carminative, promoting digestion and relieving flatulence. The drug may be given in doses of from 20 to 30 grains (1.3–2 Gm.); or a tincture (1 in 10) may be given in doses of 1 fluidrachm (4 Cc.).

Allied Drugs.—*Alpinia Galanga* Willd. (*Maranta G.* L.), the *Greater galangal*, *Radix galangæ majoris*, is rarely seen in our commerce. It resembles the preceding, but is longer and thicker, externally brown-red, internally buff-colored, and is weaker in odor and taste. Eight other species of the genus are recorded in literature as yielding aromatic products in the form either of rhizomes or seeds, several of the former being used as ginger-substitutes, of the latter as "Alpinia-" or "Galanga-cardamons."

GALBANUM, *Br., P. G.*—Galbanum.

Gummi-resina galbanum, *Galban*, *Mutterharz*, G.; *Galbanum*, Fr.; *Galbano*, Sp.

The gum-resin obtained from *Ferula galbaniflua* Boissier et Buhse (Fam. *Umbelliferæ*), and probably from other allied plants.

Origin.—Other species which have been named as sources of Galbanum are *F. rubricaulis* Boiss., *F. Schair* Borscz., *F. erubescans* Boiss., and *F. gummosa* Boiss., but it is uncertain which of these names are synonymous with that of our definition. The Galbanum plants are large, stout perennials, similar to those described under ASAFŒTIDA, and they are natives of the same general region. Little is known of the method of collecting Galbanum, but the appearance of the mass appears to indicate that it is from artificial incisions, made much after the method employed in gathering Asafetida, since sliced fragments of the root are often present. The Galbanum of the British and German pharmacopœial descriptions is that usually known as *Levant Galbanum*, and this is the one commonly understood.

Description.—Occurring in tears of variable form, these distinct or more or less agglutinated or imbedded in a brownish matrix, usually with some slices or other fragments of tissue intermixed; mass opaque or usually somewhat translucent, tears mostly less than 6 Mm. (¼ In.) in diameter, occasionally several times larger, the external color varying from a peculiar bluish-green when very fresh, to brownish or brown, or when long kept of a dark reddish-brown; rendered soft and sticky by the heat of the hand, when cold becoming dry and brittle, the fracture slightly conchoidal or, usually, granular, mostly light-yellow or yellowish-brown; odor balsamic, peculiar, and characteristic, not unpleasant; taste bitter, acrid, and disagreeable. At least 50 per cent. of Galbanum should dissolve in alcohol, and the ash should not exceed 10 per cent., not more than 8 per cent. being yielded if perfectly pure.

Moistened with alcohol, a fine purple color will be produced on the addition of a little strong hydrochloric or nitric acid. Hydrochloric acid remaining in contact with galbanum for about an hour acquires a red color, and on the gradual addition of alcohol and warming the mixture to 60° C. (140° F.) becomes transiently dark violet-colored (difference from Ammoniac, which is not colored). Water in contact with galbanum which has been heated to redness, shows a blue fluorescence on the addition of a minute quantity of ammonia water.

Lump galbanum consists sometimes of soft or harder brown masses, in which some tears are distinctly observed.

Galbanum is far less subject to adulteration than Asafetida, though earthy matters (in *Drossy Galbanum*) and vegetable tissues are often added. The latter is chiefly derived from the Galbanum plant, but foreign tissues are also included.

Constituents.—The gum-resin yields from 10 to 20 per cent. of colorless volatile oil, which becomes yellow and thick on exposure, 50 to 67 per cent. of resin, 15 to 20 per cent. of gum, and various impurities. The resin is yellowish-brown, very soft, and soluble in ether, alcohol, and alkalies. It contains 0.25 per cent. of free umbelliferon ($C_9H_6O_3$), and 20 per cent. of umbelliferon combined with galbano-resino-tannol, which amounts to 50 per cent. On destructive distillation and subsequent separation of the products it yields a colorless oil ($C_{10}H_{16}$), a clear blue oil, $(C_{10}H_{16}O)_n$, identical with the blue portion of Matricaria, fatty acids, and acicular crystals of umbelliferon. Fused with potassa, it yields resorcin and fatty acids, and boiled with nitric acid it forms *tri-nitro-resorcin* or *styphnic acid* ($C_6H_3N_3O_8$).

Oil of galbanum, which is a commercial article, has partly the odor of the drug, is of a light-yellow to brownish-yellow color, and has a specific gravity of 0.910 to 0.940. It contains d-pinene and cadinene, with other constituents.

Action and Uses.—When locally applied, galbanum acts as a counterirritant and rubefacient, and if the skin is exposed produces ulceration. Internally it acts as a stimulant expectorant and antispasmodic. In the form of a plaster it may be locally employed in the treatment of indolent ulcers and swellings for the purpose of promoting respectively suppuration or resolution. Internally it is said to be of value in the treatment of chronic bronchial affections; chronic catarrhal conditions of the intestines, and in amenorrhœa resulting from an atonic condition of the uterine mucous membrane. The internal dose is from 10 to 20 grains (0.60 to 1.3 Gm.), either in pill or emulsion, 3 times daily.

Other Galbanums.—The Galbanum described above is that commercially known as *Levant Galbanum*. Another variety is occasionally seen which is distinguished as *Persian Galbanum*. While this bears a general resemblance to the former, it differs in its peculiar shining surface and in its odor, which is characterized as turpentine-like rather than balsamic. It is usually of a darker and more reddish-brown than the Levant variety. Persian Galbanum occasionally occurs as a thick liquid, but this has the same characteristic odor as the solid form. Persian Galbanum contains less volatile oil (usually from 3 to 5 per cent. in the lump form), nearly 70 per cent. of resin, and 17 per cent. of gum. Its volatile oil is said to rotate to the right instead of to the left, as does that of the Levant variety.

GALLA, *U. S., Br.*—Nutgall.

Gallæ, P. G.; *Galla halepense, G. turcica, G. levantica, G. tinctoria, G. quercina.*—*Galls, Aleppo* or *Syrian galls*, E.; *Galläpfel, Gallen*, G.; *Galle de chêne, Noix de galle*, Fr. Cod.; *Agallas de Levante*, Sp.; *Galhas, Noz de galha*, Port.; *Noci di Galla, Galla di Lavante*, It.

An excrescence on *Quercus lusitanica* Lam. (*Q. infectoria* Olivier—Fam. *Cupuliferæ*), caused by the punctures and deposited ova of *Cynips* (*Diplolepsis*, Latreille) *Gallæ tinctoriæ* Olivier (Class *Insecta*, Order *Hymenoptera*).

Galls are official in all pharmacopœias, several of which require that the tannin-content be 60 to 70 per cent.

Origin.—*Quercus lusitanica*, the *Dyers' oak*, is a polymorphous shrub or small tree, inhabiting the eastern basin of the Mediterranean, from Greece to Persia. The tender bark of the young branches is punctured by the female of the hymenopterous insect named above, and one or more eggs are deposited in the wound. The irritation produced by this operation causes the formation of an excrescence enclosing the larva, which undergoes therein its transformations. The term *gall* is generally used to designate such excrescences formed upon any part of a plant in consequence of the puncture of an insect. If collected before the escape of the insect from them, effected by boring a hole to the exterior, the galls have the appearance described below. Otherwise they become slightly larger and lighter in weight, and assume a pale or whitish-yellow color, being then relatively deficient in tannin. Aleppo or Turkish galls are regarded as the best. Large quantities are also exported from Persia and some from Greece.

Fig. 189.

Entire. Section.

Nutgall.

Description.—Nearly spherical, about 2.5 Cm. (1 In.) or less in diameter, with a short stipe, the surface smooth except for a number of short, thick tubercles toward the summit; externally deep greenish- or bluish-gray or blackish; heavy and hard, but readily broken with a hammer, exhibiting a more or less dense granular fracture, sometimes with a waxy luster; internally, yellowish or pale brownish-gray, with a central nucleus or a cavity containing the more or less perfectly developed insect. The cellular tissue of the nucleus is mostly filled with small starch-granules and surrounded by a layer of thick-walled cells forming a shell, on the outside of which is the cellular tissue containing the tannin. This tissue has often a radiated appearance near the shell, and contains toward the surface small scattered bundles of vascular tissue. Nutgalls are nearly inodorous and have a very astringent taste. Light, spongy, and whitish-colored nutgalls should be rejected.

Nutgalls are distinguished in commerce according to their color, the *blue* or *black galls* of Syria (Aleppo) being preferred. *Smyrna galls* are usually of a grayish olive-green, more spongy in texture, and intermixed with *white galls;* the last-named are the least valuable.

Constituents.—The principal constituent of nutgalls is *tannin* or *gallotannic acid*, of which they contain about 60 per cent. Bowman (1869) assayed selected galls, finding 80 per cent., and in white galls only 30.7 per cent. 2 or 3 per cent. of gallic acid is likewise found, together with sugar, resinous and albuminous matter, and starch.

Pharmaceutical Preparations.—Ointment of Nutgall; Tincture of Nutgall, U. S. P.

Action and Uses.—Nutgall was formerly quite extensively employed for its powerfully astringent effect, but gallic and tannic acids have practically replaced it.

Other Varieties of Galls.—The number of galls produced upon different plants and by different insects is very great. They very frequently contain tannin, and a number of them are used like the official.

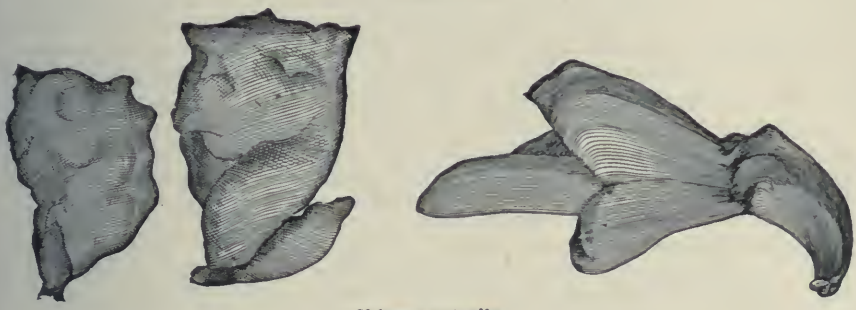
Bassorin Galls, from the same general region as the official, are imported in the form of fine powder, pressed into cakes, for dyeing purposes. They contain about 36 per cent. of tannin.

Sorian Galls are of the size of a pea, blackish, and internally not radiate. The galls which are produced upon the European oaks by different species of Cynips are of a lighter color and more spongy texture, but have an astringent taste and contain tannin.

Chinese and *Japanese Galls*, although known from a much earlier period, were not a regular article of commerce until Periera (1844) directed attention to them again. They are

produced upon the leaves or leaf-stalks of *Rhus semialata* Murray, by an insect provisionally named *Aphis Chinensis* Bell, and usually contain between 70 and 80 per cent. of tannin. They are of a very irregular shape, mostly thin, as if stalked, toward the base, much inflated above, irregularly lobed, and with few or many protuberances; they are of a reddish-brown color, but densely covered with a yellowish-gray down, consist of a thin, fragile shell, and contain in the interior numerous small dead insects. The Japanese nutgalls agree in all essential characteristics with this description, but are usually more slender and have a larger number of sharper lobes and protuberances; their origin has been referred to *Rhus japonica* Siebold. C. Hartwich (1881) found their pubescence quite dense and light-brown, and the tissue to contain unaltered starch-granules; while Chinese galls have the pubescence less dense and greenish-brown. *American Nutgalls*, as obtained from various species of *Quercus*, are light and spongy, and generally not very rich in tannin. The galls from *Quercus virens* Aiton, produced in Texas, are more analogous to Aleppo galls, but not tuberculate; they contain

FIG. 190.



Chinese nutgalls.

about 40 per cent. of tannin. The so-called *California oak-balls* are derived from *Quercus lobata* Engelmann, are about 5 Cm. (2 In.) in diameter, orange-brown and somewhat glossy externally, soft and spongy within, and appear to contain much tannin.

Tamarisk Galls are collected from *Tamarix orientalis* Forst., which grows in southern and southwestern Asia. They are $\frac{3}{12}$ Mm. ($\frac{1}{8}$–$\frac{1}{2}$ In.) thick, subglobular, knotty, and are said to contain from 40 to 50 per cent. of tannin. Similar galls are obtained in Algeria and Morocco from *T. Africana* Poir. The brown-red, fibrous, bitter, and astringent bark of *T. gallica* L., and the leaves of the same plant, are used in southern Europe.

Myrobalans.—Similar to Galls as to their general properties and uses are the dried fruits of *Buceras Bellirica* (Gærtn.) Lyons (*Myrobalanus B.* Gærtn.; *Terminalia B.* Gærtn.), the *Round* or *Belleric myrobalans*, and of *B. Chebula* (Retz.) Lyons (*Terminalia C.* Retz.; *Myrobalanus C.* Gærtn.; *Bucida comintana* Blanco), the *Long*, *Indian*, or *Black myrobalans*, *Ink-nuts*, *Hare-nuts* (Fam. *Combretaceæ*), of the East Indies. These fruits are the product of good-sized trees. Of the first-named, there are two varieties, so called, though they are more likely distinct species. The smaller one is nearly globular, with a suddenly contracted base, a little more than a half inch in diameter, brown or gray-brown, 3-ridged, finely woolly or velvety. The pulp is the astringent part. The pentagonal stone contains an oily seed. The larger form is oval-ovoid and more than an inch in length. The amount of tannin ranges from 5 to 15 per cent. or more. The kernel is edible, but there are some ill-defined claims that it is sometimes poisonous. The Long, or Chebula kind is an inch to an inch and a half long, oval or obovoid, with 5 or 6 shallow furrows separating as many indistinct faces. They are also collected unripe, when they dry black and shrivelled and only about half as large. They contain from about 30 to 45 per cent. of tannin. The tannin in all the varieties is mostly gallotannic acid.

Of *B. Arjuna* (Bedd.) Rusby (*Terminalia A.* Bedd.), the bark is used in India as an astringent. The kernel of *B. Catappa* (L.) Lyons (*Terminalia Catappa* L.; *Buceras Bucida* Crantz; *Bucida Buceras* Sieber) yields a seed which is used as a substitute for sweet almonds.

Phyllanthus Emblica L. (*Emblica officinalis* Gærtn.—Fam. *Euphorbiaceæ*), an East Indian tree, yields *emblic myrobalans*, which are drupaceous, subglobular, 6-grooved, and 3-celled, each cell containing 2 small brown-red glossy seeds.

Under the name *Vallonea*, *Valonia*, or *Acorn cups*, the involucre of the fruit of various species of *Quercus*, especially of *Q. Vallonea* Klotsch, of the Levant, are used for tanning purposes.

GAMBIR, *U. S.*—Gambir.

Catechu, Br., P. G., U. S., 1890; *Catechu pallidum, Terra japonica, Pale Catechu, Gambier*, E.; *Gambir, Gambir-Catechu*, G.; *Gambir cubique*, Fr.

An extract prepared from the leaves and twigs of *Ourouparia Gambier* (Hunter) Baill. (*Nauclea G.* Hunter; *Uncaria G.* Roxb.—Fam. *Rubiaceæ*).

Several pharmacopœias, including our own, recognize this to the exclusion of that from *Acacia Catechu*, while others authorize the use of either. The Russian requires that it contain not less than 60 per cent. of tannin substances.

Origin and Preparation.—The Gambir plant is a stout woody vine of the East Indian islands, climbing high over shrubbery and trees by means of stout hooks, formed from old peduncles. It has long been cultivated in the Singapore region, and was some years ago extensively distributed to British tropical botanical gardens, for purposes of propagation and the encouragement of its cultivation. This was regarded by the British government as one of the most important plant-distributions which they had ever made. The young, leafy shoots are boiled in water for 6 hours, being continually stirred and bruised, and the decoction evaporated, by farther boiling, to the proper consistency, then allowed to cool under constant stirring of a peculiar character. After about 25 minutes, the Gambir suddenly contracts and thickens, probably by the sudden crystallization of the catechuic acid. It is allowed to harden in various forms, the best and purest being usually that formed into thin cakes, flakes, or small cubes. It is nearly all exported from Singapore in wooden cases.

Description.—In small cubes or cakes, or in large irregular masses; externally dull grayish-brown, usually with darker-brown streaks, somewhat lighter internally; brittle to friable, slightly porous, exhibiting numerous fine acicular crystals under the microscope; of a bitterish, astringent, finally sweetish taste; partly soluble in cold water, yielding with hot water a turbid solution and with hot alcohol a clear dark-brown solution, leaving undissolved only the impurities, which should not exceed 15 per cent., and which, examined under the microscope, should be found to consist largely of parenchymatic tissue and to contain numerous epidermal hairs (distinction from Catechu, which shows woody fibers and large-pitted vessels); upon incineration it should yield not over 6 per cent. (usually not more than 5 per cent.) of ash, chiefly earthy salts.

Constituents.—Gambir yields the same substances as CATECHU, but usually less catechutannic acid and more catechin. Twelve samples (Lehmann) yielded 25–38 per cent. of tannin and 20–29 per cent. of catechin.

Action and Uses.—The uses of pale catechu are mentioned under CATECHU (which see).

Other Species.—It is said that a part of the Gambir product comes from *O. acida* (Roxb.) Lyons (*Uncaria a.* Roxb.), of the same region, and there appears no good reason why it should not be extracted from other of the 30 species of the genus.

Akakia, of India, is a catechu-like extract obtained from the fruit of *Acacia Arabica* W., there known as *Bablah* or *Web-web*, and containing about 22 per cent. of tannin. The bark of this species is also used under the name *Babul*.

GAULTHERIA.—Gaultheria.

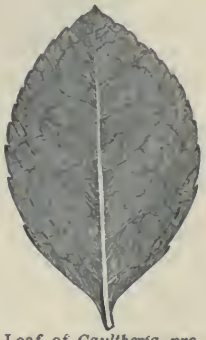
Folia Gaultheriæ.—Wintergreen, Partridge-berry, Box-berry, Checker-berry, Spice-berry, Chicken-berry, E.; *Canadischer Thee, Bergthee*, G.; *Feuilles de gaulthérie (de palommier), Thé du Canada, Thé de Terre-neuve*, Fr.

The dried leaves of *Gaultheria procumbens* L. (*Brossæa p.* O. Kuntze; *G. humulis* Salisb.; *G. repens* Raf.—Fam. *Ericaceæ*).

Origin.—This plant is very common throughout eastern North America, and is represented in the Northwest by an almost identical but rather larger species, *G. Shallon* Pursh. In partly open woodlands it often becomes very abundant, carpeting large patches to the almost total exclusion of other growth. It is a pretty little evergreen, a few inches in height, spreading by prostrate or partly subterranean creeping stems. The leaves grow in a little terminal rosette, and the white, wax-like, bell-shaped flowers are recurved and concealed underneath them. The scarlet, berry-like, inferior fruit, about as large as a black currant, is persistent and remains unchanged for nearly a year. This

fruit is gathered and eaten under the name *Checker-berry*, and is found frequently in the markets. The entire plant is commonly torn up and gathered by the use of a garden rake. After drying, most of the leaves are readily shaken off, and the remainder may be distilled along with another portion of the plants. Gaultheria should be gathered in the autumn, since during the growing season the new, thin, and inferior leaves occur with the others.

Fig. 191.



Leaf of *Gaultheria procumbens* (Nat.).

Description.—Short-petioled, about 4 Cm. (1½ In.) long and from two-thirds to nearly equally as broad, roundish-oval to obovate, finely toothed, the elongated teeth appressed to the thickish margin; thick and coriaceous, mucronate, smooth and somewhat shining, paler underneath; odor and taste agreeably and peculiarly aromatic; astringent.

Constituents.—The important constituent is from 0.5 to 1 per cent. of volatile oil (see Oleum Gaultheriæ). With this occur tannic acid, *arbutin*, *ursone*, and *ericolin* (see Ericaceæ), but no andromedotoxin.

Action and Uses.—The properties of this drug depend entirely upon its volatile oil (see Oleum Gaultheriæ).

Other Species.—The genus *Gaultheria*, L., contains about a hundred species, many of them in the Andes. The greater number are very little, if at all aromatic, though *G. fragrantissima* Wall., of India, and *G. punctata* L., *G. leucacarpa*, and *G. nummularioides*, *G. Shallon* D. Don (*G. repens* Bl.), of Java, are strongly so; and a Mexican species is said to yield far more oil than *G. procumbens*.

Chiogenes hispidula (L.) T. et G. (*Vaccinium h.* L.; *C. serpyllifolia* Salisb.; *C. Japonica* Gray), the *White tea-berry*, *W. wintergreen*, or *W. cranberry*, *Ivory plum*, *Creeping snow-berry*, *Running birch*, *Mountain partridge-berry*, a creeping evergreen, growing in patches in eastern and northern North America, is rich in methyl salicylate or oil of wintergreen, and is used similarly to Gaultheria. For other sources of this oil, see Methylis Salicylas.

GELATINUM, *U. S.*, *Br.*—Gelatin.

Gelatina alba, P. G.; *Gélatine*, Fr.; *Weisser Leim*, *Gelatine*, G.; *Gelatina*, Sp.

The air-dried product of the hydrolysis of certain animal tissues, as skin, ligaments, and bones, after treatment with boiling water.—U. S.

Preparation.—Bones, hoofs, horns, animal skins, etc., previously cleansed by washing in cold water or treatment with dilute alkali solution, are placed upon a sieve or perforated diaphragm in a boiler, and boiled with water until the collagen is rendered soluble and the solution stiffens to a jelly on cooling. While hot the solution is skimmed to remove fat and extraneous matter, and strained and clarified to remove impurities. The purified saturated solution is allowed to cool, the jelly cut into cakes, and these placed on nettings to dry. When made from carefully selected material (usually fresh bones) it constitutes the *gelatin* of commerce, while the impure and inferior grades produce products known as *colla*, *colla animalis*, *glutinum*; *glue*, E.; *colle*, *colle forte*, Fr.; *Leim*, G.

A pure gelatin may be prepared from the best qualities of commercial gelatin by soaking the gelatin for several days in successive quantities of cold water, whereby saline and soluble constituents are removed. The gelatin is then dissolved in hot water and filtered direct into alcohol; the resulting precipitate is separated, redissolved in water, and again precipitated in alcohol.

Properties.—Gelatin occurs commercially in the form of thin rectangular pieces bearing impressions of the netting upon which it has been dried, or in smooth sheets which are either thin and transparent, or thicker, more or less porous, and opaque. It also occurs cut into shreds or in the form of a coarse powder.

"An amorphous, more or less transparent, solid, usually shredded or in thin sheets; colorless or with a slight yellowish tint, inodorous, and having a slight, peculiar, almost insipid taste. Unalterable in the air when dry, but putrifying rapidly when moist or in solution. When heated, gelatin is decomposed, leaving a slight mineral residue, which should not exceed 2 per cent. of the original weight. Gelatin is insoluble in cold water, but when immersed it swells and softens, gradually absorbing from 5 to 10 times its

weight of water. It is soluble in boiling water, acetic acid, and glycerin; insoluble in alcohol, ether, chloroform, benzene, carbon disulphide, and fixed and volatile oils. When dissolved in boiling water (1 in 50), it should solidify upon cooling, and form a transparent jelly. An aqueous solution of gelatin (1 in 5000) is at once rendered turbid on the addition of tannic acid test-solution, the precipitate being insoluble in the presence of an excess of the reagent. Gelatin is precipitated from its aqueous solution by mercuric chloride test-solution in excess; it is not precipitated by a solution of alum, by ferric chloride test-solution, or by lead acetate test-solution. If potassium dichromate test-solution be added to a solution of gelatin in hot water, the jelly which forms on cooling becomes insoluble in warm water after exposure to light."—U. S.

When its solution in water is boiled for a long time, or more rapidly by superheating the solution to 140°C. (284° F.), the gelatin loses the property of gelatinizing on cooling, being altered to *gelatose* or *paragelatose* (terms applied by Dastre and Floresco, *P. J. Tr.*, 1895), or *gelatones* (gelatin-peptones). Boiled with solutions of fixed alkali hydroxide or with sulphuric acid, ammonia, *glycocoll*, $C_2H_5NO_2$, and *leucin*, $C_6H_{13}NO_2$, are obtained among other products.

The aqueous solutions of gelatin are viscid, indiffusible, strongly lævorotatory (the value of $[a]_D$ is —130° at 30° C., Hoppe-Seyler), and are not precipitated by dilute solutions of alum, ferric chloride, or lead acetate (distinction from chondrin), but yield precipitates with tannin, chlorine-water, bromine-water, corrosive sublimate, platinic chloride, picric acid, phosphomolybdic acid, and phosphotungstic acid. Gelatin is completely precipitable by saturating its aqueous solution with ammonium sulphate, magnesium sulphate, or zinc sulphate.

If a solution of gelatin be mixed with formaldehyde, the gelatin is rendered hard and insoluble after evaporation and drying the residue. By dry distillation gelatin yields ammonia and a highly offensive oil, bone oil (Dippel's animal oil), containing various pyridine bases and empyreumatic products.

Good gelatin should be colorless and odorless, form neutral solutions in water, contain not over 2 per cent. of ash, and when 1 part is dissolved in 100 parts of hot water the solution on cooling should set to a jelly. Some of the commercial gelatins frequently show an acidity of 0.2 per cent., due to the use of acids in bleaching the gelatin solution.

Gelatin consists principally of *glutin*, and contains about 50 per cent. of carbon, 18 per cent. of nitrogen, 6.5 per cent. of hydrogen, 25 per cent. of oxygen, and 0.5 per cent. of sulphur. The variation in the hardening and binding qualities of gelatin is attributable to variations in the accompanying amounts of chondrin and gelatones.

Pharmaceutical Uses.—Gelatin is extensively used for preparing ordinary court-plaster, for gelatin-coating pills, and in the manufacture of disks, lozenges, and suppositories, as well as for making the well-known hard and soft gelatin capsules. The latter are made by dipping polished moulds made of either metal, bone, or wood, of the desired size and shape and attached to a suitable disk by means of a handle, into a melted gelatin mass kept at a temperature of about 40° C. (104° F.). Before dipping, the moulds are rubbed with a soft oiled cloth to prevent adhesion of the gelatin, and after taking them from the melted mass they are rotated for a few minutes so as to insure a uniform film. After 30 minutes the gelatin mass will have become sufficiently firm to allow the capsules to be stripped from the moulds and laid aside to dry. The composition of the gelatin mass may vary with different manufacturers. Some recommend for hard capsules a mixture of 1 part of white gelatin and 3 parts of water, to be melted on a water-bath at a temperature of 65° C. (149° F.), and for soft capsules a mixture of 1 part each of white gelatin and water and 2 parts of glycerin. Other authorities propose for hard capsules a mixture of: gelatin, 30 parts; acacia and sugar, of each, 5 parts; and water, 25 parts. For soft capsules a mixture of: gelatin, 50 parts; acacia and sugar, of each, 15 parts; glycerin, 12½ parts; and water, 80 parts. The French pharmacopœia directs for elastic capsules a mixture of: white gelatin, 25 parts; sugar, 8 parts; glycerin, 10 parts; and water, 45 parts.

Gelatin has been successfully employed for the purpose of detannating wines, and offers many advantages over other agents recommended for the same object. It may be used in form of a No. 40 powder and in proportion of ½ ounce to 1 gallon of wine. The mixture should be kept in a cool place, and occasionally shaken during 48 hours, and then filtered.

Action and Uses.—Gelatin has been used in medicine quite largely during the last few years as a means of checking hemorrhage which cannot be controlled by pressure or a ligature, as it acts both locally and generally as an aid to coagulation of the blood. For the purpose of controlling oozing capillary hemorrhage it may be applied locally to the bleeding area in 10 per cent. solution. When used to check internal hemorrhages it is commonly given hypodermically in normal salt solution (0.9 per cent.) in the strength of about 1 to 2 per cent., but care must be taken that the solution is sterilized, so as to prevent local infection or even tetanus. Care must also be exercised that it does not enter a vein and cause an embolus. Gelatin when taken by way of the stomach also increases the coagulability of the blood, and administered in this way or given by the hypodermic needle has been used to favor coagulation in cases of aneurism.

GELATINUM GLYCERINATUM, *U. S.*—Glycerinated Gelatin.

Gelatina glycerinata, Gelatum glycerini, Glycerin jelly, E.; *Gelée glycerinée,* Fr.; *Glycerinleim,* G.

Preparation.—Gelatin, 100 Gm.; glycerin, 100 Gm,; water, a sufficient quantity. To the gelatin add sufficient water, which has been previously boiled and cooled, to cover it; allow it to stand 1 hour; pour off the water and allow the gelatin to drain for a few minutes; then transfer it to a tared dish, add the glycerin, and heat it on a water-bath until the gelatin is dissolved. Strain the solution while hot, and continue the heat on the water-bath until the product weighs 200 Gm. When cold, cut the mass into pieces, and preserve them in suitable containers.—U. S.

The supplement to the German Pharmacopœia (1895) directed 25 parts of white gelatin to be macerated with 25 parts of water for ½ hour, after which 50 parts of glycerin are added and perfect solution effected by heating on a water-bath. A still softer preparation was directed to be made by using only 15 parts of gelatin with 25 parts of water and 50 parts of glycerin.

Glycerinated gelatin, when prepared by the official formula, forms a firm mass when cold, is almost colorless in thin layers, and has no odor. It is admirably adapted as a vehicle for rectal and vaginal suppositories, as well as nasal and urethral bougies, being diluted with varying proportions of water and glycerin to suit the various combinations with solid extracts, chemicals, and vegetable powders. For general purposes the addition of 25 parts each of water and glycerin to 50 parts of glycerinated gelatin, previously melted, will prove satisfactory, yielding a mass which, when cold, is flexible, yet sufficiently firm, and melting readily at the temperature of the body. (See also SUPPOSITORIA.)

Action and Uses.—Glycerinated gelatin possesses no medicinal value, except as a vehicle for other drugs, as described above.

GELSEMIUM, *U. S.*—Gelsemium.

Gelsemii radix, Gelsemium root, Br.—*Yellow jessamine or jasmine, Carolina or American Yellow jessamine, Yellow or Evening trumpet flower,* E.; *Gelsemie, Giftjasmin,* G.; *Jasmin sauvage,* Fr.; *Gelsemio,* Sp.

The dried rhizome and roots of *Gelsemium sempervirens* (L.) Ait. f. (*Bignonia s.* L.; *Lisianthus s.* Mill.; *Anonymos s.* Walt.; *G. nitidum* Mx.; *G. lucidum* Poir.—Fam. *Loganiaceæ*).

This plant should not be confused with the tree Jasmine (*Jasminum* L.—Fam. *Oleaceæ*), which has also been known under the name *Gelseminum,* and which has but 2 stamens, while Gelsemium has 5.

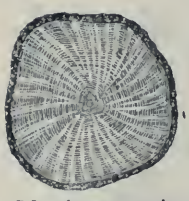
Gelsemium is official in the more important pharmacopœias.

Origin.—The Carolina Jessamine is a high-climbing woody twiner of moist woodlands of the Atlantic and Gulf region from Virginia to Central America. It bears handsome, opposite, evergreen, shining, lanceolate, entire leaves, and large, fragrant, solitary or cymose, axillary flowers, the corolla bright-yellow, funnel-shaped, shortly and broadly 5-lobed, the lobes emarginate. It is altogether one of the most beautiful and pleasing of our native plants. The drug is commonly collected just after the plant comes into flower. It is often adulterated with the aërial portion of the stem.

Description.—Rhizome cylindrical, short-flexuous, elongated or cut in sections of variable length, mostly from 0.5 to 1.5 Cm. ($\frac{1}{5}$ to $\frac{3}{5}$ In.) and occasionally 3 Cm. (a little more than an inch) in diameter, the roots much thinner, a few elongated, unbranched, coarsely hair-like, tough rootlets usually attached; externally of a light yellowish-brown, commonly with some purple or purplish-brown longitudinal streaks or patches; heavy, hard, and tough; internally yellowish-white; fracture of the rhizome splintery, the roots breaking with half the fracture transverse, the other oblique or short-splintery; bark thin, closely adhering, that of the rhizome with fine, silky bast-fibers, the wood porous, with numerous fine medullary rays; odor peculiar; taste slightly aromatic, bitter.

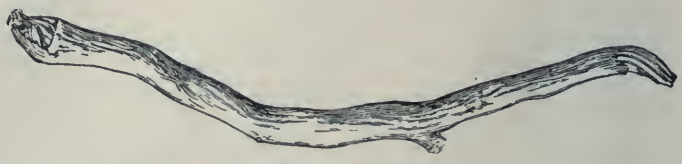
Adulteration with the aërial stems can be detected by the thinness and dark-purplish color of the latter. Sayre has pointed out that their corky layer is only about 3 to 6 cells thick, while that of the rhizome is 14 to 16, and that the latter has the bast-fibers in an interrupted ring or scattered, whereas in the aërial stem they are in thick bundles close to the cambium. He also states that the aërial stem is destitute of alkaloid. Dohme states that the similar roots of Jasminum are sometimes intermixed, and that they can be distinguished by the absence of indurated pith-cells, which occur in Gelsemium, by the abundance of starch-grains in the pith and in the medullary ray-cells, and by the bast-fibers around the sieve-tubes.

Fig. 192.



Gelsemium sempervirens Ait.: transverse section of root.

Fig. 193.



Gelsemium root (⅔ Nat.).

Fig. 194.

Gelsemium rhizome (⅔ Nat.).

Constituents.—The rhizome and roots contain 0.5 per cent. of volatile oil, 4 per cent. of two resins, one dry and acrid, the other fatty, 0.2 to 0.5 per cent. of alkaloid, 0.3 to 0.4 per cent. of gelsemic (gelseminic) acid, starch, gum, and pectin. *Gelsemic acid* ($C_{13}H_{11}O_5$, Coblentz), a colorless, odorless, and nearly tasteless crystalline body, differs from æsculin ($C_{15}H_{16}O_9$), and though an active reducing agent for copper and other metallic salts, is not a glucoside. Schmidt (1898) has shown it to be identical with beta-methyl-æsculetin [$C_9H_5(CH_3)O_4$], found in scopola root and other plants, and suggests that the name gelsemic acid be dropped. It is soluble in 1490 parts of water, 415 parts of absolute ether, 135 parts of chloroform, and readily in hot alcohol, glacial acetic acid, or alkalies, with the latter of which it produces a blue fluorescence. *Gelsemine* ($C_{12}H_{14}NO_2$, the "crystalline gelseminine" of Germany) is a colorless, odorless, intensely bitter, crystalline alkaloid, sparingly soluble in water, freely in acids, and in chloroform and ether. It is accompanied by *gelseminine* (Thompson, Cushny), an amorphous alkaloid whose hydrochloride is more readily soluble in water than that of gelsemine. The stem of the plant contains no alkaloid nor gelsemic acid.

Pharmaceutical Preparations.—Fluidextract of Gelsemium; Tincture of Gelsemium, U. S. P.

Action and Uses.—When given internally gelsemium acts as a powerful depressant to the respiratory, circulatory, and nervous systems. It acts as a depressant to the heart muscle and vagus nerves and under its influence there is a diminution in the pulse-force and blood-pressure. It primarily depresses the sensory side of the spinal cord; but later, if given in large amount, depresses the motor side. The drug has no effect upon

the spinal nerves, but the motor cranial nerves are paralyzed by large doses. In moderate amounts it causes the respiration to become slow and feeble, and in lethal quantities paralyzes the respiratory center. When the alkaloid gelsemine is locally employed in the eye, it produces mydriasis, probably by depressing the peripheral ends of the oculomotor nerves.

Gelsemium was formerly employed as a circulatory sedative in controlling the early stages of acute sthenic inflammations, but at present is rarely employed for this purpose. It has been recommended in the treatment of tetanus, chorea, malarial and typhoid infections, and in delirium tremens, but is probably of no benefit in these conditions, and in typhoid states is distinctly harmful. It has been found useful in the treatment of headache and migraine; and in asthma, whooping-cough and nervous cough, spasmodic dysmenorrhœa, torticollis and other conditions depending upon localized muscular spasm. A solution of the alkaloid gelsemine (8 grains—0.5 Gm.) (water 1 ounce—30 Gm.) has been employed as a mydriatic, and is said to be equal in potency but much more transient in its effects than atropine.

Poisonous doses of gelsemium produce a sensation of languor, relaxation, and muscular weakness, which may be followed by paralysis if the dose is sufficiently large. The face becomes anxious, the temperature subnormal, the skin cold and clammy, and the pulse rapid and feeble. Dropping of the upper eyelid and lower jaw, internal squint, double vision, and dilatation of the pupil are prominent symptoms. The respiration becomes slow and feeble, shallow and irregular, and death occurs from centric respiratory failure, the heart stopping almost simultaneously. Consciousness is usually preserved until late in the poisoning, but may be lost soon after the ingestion of a fatal dose. The treatment of gelsemium poisoning consists in the prompt evacuation of the stomach if the patient's condition permits, and in the early administration of ammonia, strychnine, atropine, and digitalis. The dose of fluid extract of gelsemium is from 2 to 5 minims (0.10–0.3 Cc.); and of the tincture, from 5 to 15 minims (0.3–1 Cc.). Gelsemine hydrochloride may be employed in doses of $\frac{1}{200}$ grain (0.0003 Gm.).

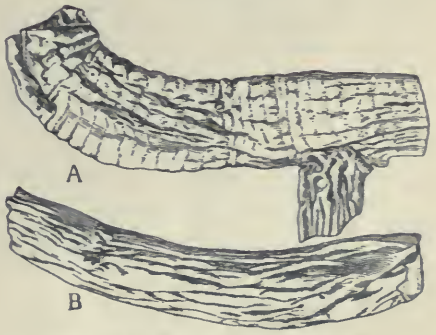
GENTIANA, *U. S.*—Gentian.

Gentianæ radix, Br.; *Radix gentianæ*, P. A., P. G.; *Radix gentianæ rubræ vel luteæ (vel majoris).—Gentian-root, Bitter-root, Fel-root*, E.; *Racine de gentiane (de gentiane jaune)*, Fr.; *Enzianwurzel, Bitterwurzel, Rother (Gelber) Enzian*, G.; *Genciana*, Sp.; *Argencana*, Port.; *Genziana*, It.

The dried rhizome and roots of *Gentiana lutea* L. (Fam. *Gentianaceæ*).

Official in all pharmacopœias, a number of which admit in addition, or have previously admitted, the species *G. Pannonica* Scop. (*G. punctata* Jacq.), *G. purpurea* L., *G. punctata* L. (*Pneumonanthe p.* Schmidt; *Dasystophana p.* Borckh.; *G. campanulata* Jacq.). These roots are all shorter and thinner than that of *G. lutea*, and that of *G. Pannonica* is scarcely annulate.

FIG. 195.



Gentian: A, rhizome and, B, root (¾ Nat.).

Origin.—A tall, stout, hollow-stemmed perennial herb of open or partly open grassy places on the mountains of southern and central Europe (for generic characters see GENTIANACEÆ). Its large flowers are bright-yellow and spotted, and occur in axillary clusters. The underground portion is frequently a yard in length, and may have several long branches. It is commonly collected in flower. To prevent its extermination, the Austrian government imposed a heavy fine for collecting a root not at least 2 Cm. (nearly an inch) in diameter at the top, this ordinarily requiring a 3 years' growth and insuring its previous propagation by seed. The United States supply comes chiefly from France.

Description.—In cylindraceous, usually slightly flattened, curved or crooked pieces of indefinite length, and from 0.5 to 3.5 Cm. (¼ to nearly 1½ In.) thick, or in longitudinal

slices of the same; externally yellowish brown to dark brown, strongly and crookedly longitudinally wrinkled, and marked with lighter-colored circular root-scars, the rhizome finely or heavily annulate; somewhat tough and flexible when damp, rather brittle when dry, the fracture short but uneven, the bark thick, reddish-brown, separated by a dark-brown line from the yellowish or reddish-yellow inner portion; free from starch; odor strong, characteristic; taste very bitter, slightly sweetish.

The yellowish-brown powder contains no starch, calcium oxalate crystals, nor tannin.

Constituents.—Gentian-root contains fatty and resinous matter, much gum, pectin, 12 to 15 per cent. of glucose, gentiopicrin, gentisin, and a yellow coloring-matter identical with quercitrin or one of its products, and crystallizing in stellate clusters of yellow needles.

Gentiopicrin ($C_{20}H_{30}O_{12}$) occurs in neutral, colorless or pale-yellow, bitter needles, readily soluble in water, less so in dilute alcohol and hot absolute alcohol, and insoluble in ether or cold alcohol. It is a glucoside to which the odor and bitterness of the drug are mostly due, and with dilute acids it splits into glucose and *gentiogenin*, a yellowish-brown, amorphous, neutral, bitter powder soluble in alcohol. The fresh root yields 0.1 per cent. of gentiopicrin.

Gentisin (gentianin or "gentisic acid," $C_{14}H_{10}O_5$) occurs in yellow, tasteless prisms, nearly insoluble in water and ether, sparingly soluble in alcohol, and with alkalies forming yellow, crystalline, soluble compounds. Fused with potassa, it yields phloroglucin ($C_6H_3(OH)_3$), acetic acid, and oxysalicylic or gentisinic acid ($C_7H_6O_4$). Boiled with hydriodic acid, it yields *gentisein* ($C_{13}H_8O_5$), which crystallizes in fine straw-colored needles. Gentisin is methyl-gentisein.

From the fresh root, but not when dried, is obtained a fermentable, crystalline sugar, *gentianose* ($C_{16}H_{66}O_{31}$), which does not reduce Fehling's Solution. The dark-green color produced in gentian preparations by ferric chloride has been charged to the presence of tannin, but Maisch and Van Itallie found no tannin, and attribute the reaction to gentisin. Ville regards gentisin as probably a gentiotannic acid. Patch found the resinous matter associated with a principle not yet isolated, which gives a greenish-black color with ferric chloride, and precipitates tartar emetic, cinchonidine sulphate, and gelatin. Owing to the large amount of sugar, the roots are used in the Alps, Jura, and Vosges Mountains for the manufacture of an alcoholic beverage.

Pharmaceutical Preparations.—Compound Tincture of Gentian, Extract of Gentian, U. S. P.; Elixir of Gentian, Elixir of Gentian with Tincture of Chloride of Iron, Ferrated Elixir of Gentian, N. F.; Fluidextract of Gentian, U. S. P.; Stronger Compound Infusion of Gentian, N. F.

Action and Uses.—Gentian may be classed as one of the best of the simple bitters, exciting the flow of the gastric juice, promoting the appetite, and aiding digestion. It has proved useful in many forms of dyspepsia, and is a good remedy for overcoming the loss of appetite following acute infectious diseases. It may be employed for its tonic effect in the treatment of mild malarial infections, and in the subacute gastric and intestinal catarrh of children. The dose of the powdered drug is from 10 to 30 grains (0.60–2), usually administered in the form of a fluidextract or tincture.

Gentianaceæ (*the Gentian Family*).—Genera about 60, species about 1000, all herbs, with the exception of a few soft-shrubby tropical species, and almost invariably smooth. None is poisonous. With the exception of a few species of *Coutoubea*, used as anthelmintics, all of the hundred or more species which have been employed medicinally are used for their bitter and stomachic, and indirectly somewhat laxative properties, much like *Gentiana*, with which the constituents also agree in a general way, so far as known. The laxative properties are typified by Menyanthes. A few of the members are wanting in these bitter properties, and several of these are somewhat used locally as potherbs. Owing to this uniformity in properties, and the great availability of plants so widely distributed, their recognition is so important that the following botanical characters of the family are introduced: leaves opposite, entire, estipulate, usually nerved or ribbed; inflorescence solitary or cymose, the cymes either panicled, or solitary and axillary or terminal; flowers regular or somewhat oblique, 4- to 5-merous; corolla gamopetalous; stamens of the same number as and alternate with the corolla-lobes, and borne upon the corolla; disk none or inconspicuous; ovary superior, 1-celled or rarely falsely 2-celled, the anatropous or amphitropous ovules numerous, on parietal placentæ; fruit a dehiscent capsule, occasionally indehiscent and rarely fleshy; embryo small, in copious albumen.

The most important medicinal genus is *Gentiana*, L., distinguished by the following characters: leaves and flowers almost invariably sessile, the latter axillary or terminal, erect or

rarely pendulous, variously colored and showy; calyx tubular; corolla contorted or imbricated, from campanulate to salver-form, or rarely nearly rotate, the lobes, with rare exceptions, spreading; stamens affixed to the tube of the corolla, the anthers or the connective pointed; ovary 1-celled, the placentæ not intruded, sometimes laterally extended; style short, with 2 spreading or recurved stigmas; capsule 2-valved, the placentæ very thin. This genus comprises upward of 300 species, widely distributed through temperate regions, including high mountains in the tropics, and some extending into the Antarctic Zone. They possess, almost without exception, the bitter taste of the official drug, and such as have been examined appear to contain the same constituents and to be available for the same uses. More than 30 species are named by Dragendorff as being so used. In collecting the official *Gentiana*, several other species growing with it, are added, especially the 3 named above in connection with our definition.

Several American species have been more or less employed medicinally, under the name *Blue gentian-root*, but, owing to their much greater cost, without corresponding superiority, they are now very little used. These roots were official in the U. S. P. of 1870 under the title *Gentiana Catesbæi*. Maisch referred the drug to *G. Andrewsii* Griseb. (*G. alba* Muhl.), the *Closed*, *Barrel*, or *Bottle gentian*; *G. Saponaria* L. (*G. Catesbæi* Walt.), the *Soapwort*, *Rough* or *Marsh gentian*, or *Harvest bells*; and *G. fimbriata* Vahl. In all probability this list should have included also *G. Elliottii* Chapm. (*G. Catesbæi* Ell.; *G. scaberrima* Kusn.), or *Elliott's gentian*. Blue gentian consists of a number of nearly simple roots about 7.5 Cm. (3 In.) or more in length, branching from an annulated head about 1.3 Cm. (½ In.) long and a fourth as thick. They are of a pale-orange or yellowish-brown without, deeply short-wrinkled, brittle, the fracture short or somewhat spongy, pale-yellow within, the bark thick, the ligneous cord quite thin.

G. Buergiri Miq. is the Japanese *Rew-tang-soh*; *G. Kurroo* Royle (*Pneumonanthe Kurroo* Don) is the East Indian *Karu*, *Nilkant*, or *Kanal-phul*; *G. decumbens* L. (*G. dahurica* Fisch.; *G. Olivieri* Gris.; *G. Pneumonanthe* Smel.; *G. adscendens* Pall.) is the *Gufas* of Turkestan or *Gul-i-Gafit* of India. *G. Tannitami* Azara (*G. thyrsoidea* Hook.) is used in Peru as a cinchona-substitute.

Frasera, *American colombo* (*Radix Colombo Americanæ*), *Indian lettuce*, *Pyramid flower*, *Meadow pride* (E.), *Racine de colombo de Mariette* or *d'Amerique* (Fr.), *Amerikanischer Colombowurzel* (G.), is the root of *Frasera Carolinensis* Walt. (*F. Walteri* Mx.), a handsome pyramidal-branching plant of the eastern and central United States, occasionally growing in Canada. The commercial drug closely resembles Gentian in everything except the color, the external surface being yellowish or pale-orange, the color within pale-yellow, a dark-brown cambium-zone separating the bark, which is rather thick and exhibits 2 differently colored layers, from the meditullium, which exhibits scarcely any radiate structure. The drug formerly occurred in transverse disks, like Calumba, but entirely lacking in the radiate structure which characterizes that drug. It is now almost always seen in longitudinal slices, the thick bark curved so as to present rounded edges. It closely resembles Gentian in odor and taste. The constituents are practically identical with those of Gentian, as are the uses.

Centaurea.—Next in importance to the Gentians are the *Erythræas*, several species of which have been quite largely employed as simple bitters. The principal one is *E. Centaurium* (L.) Pers. (*Gentiana C.* L.), the *European* or *Smaller centaury*, *Bloodwort*, *Christ's ladder*, or *Mountain flax* (E.), *Tausendguldenkraut*, *Rother Aurin* (G.), *Petite Centaurèe* (Fr.), *Centaura menor* (Sp.), the drug sold as *Herba Centaurii minoris*. The plant is 25 to 40 Cm. (about a foot) high, much branched, the branches erect, most of the leaves in a basal rosette, those of the stem oblong, blunt, sessile, 2.5 to 5 Cm. (1 to 2 In.) long; flowers rose-purple, in compound cymes, sessile or nearly so, 12 to 15 Mm. (about ½ In.) long, the 4 or 5 calyx-lobes narrow, keeled; corolla-lobes about half the length of their tube and about as long as the calyx-lobes, obtuse; anthers elongated and spirally twisted in age; style filiform, the 2 stigmas oval.

E. stricta Schiede and *E. tetramera* Schiede are used in Mexico under the name *Canchalagua*, the former being also called *Cachalohuai*, the latter *Tlanchalagua*. *E. chilensis* Pers. (*Chironia C.* Willd.; *Gentiana Peruviana* Griseb.) is called *Canchalagua* in Chile. *E. Roxburghii* Don is the Indian *Chota chirata*. The drug known in India as *Kanturium* and in China as *Lung-tau* is probably also an *Erythræa*.

A number of species of the genus *Sabbatia*, Adans., are similarly used and even employed as substitutes for quinine in malaria. The most important of these is *S. Elliottii* Steud. (*S. paniculata* Ell.; *Swertia difformis* L.), the *Quinine flower* or *Quinine herb*, *American* or *Larger centaury*, of the southeastern United States. The stem is 25 to 50 Cm. (10 to 20 In.) high, terete and diffusely branched; leaves sessile, 6 to 12 Mm. (¼ to ½ In.) long, obovate or oblanceolate, and the upper ones linear; calyx-lobes almost filiform and about one-fourth the length of the rose-colored corolla. The plant is inodorous, and has a persistent, purely bitter taste. *S. angularis* (L.) Pursh. (*Chironia a.* L.), of dry hills in the eastern United States, similarly employed, is also known as *American centaury* or *American red centaury*, *Bitter clover*, *Rose pink*, or *Square-stemmed sabbatia*. It reaches a height of 2 or 3 feet, has the quadrangular stem narrowly winged, the leaves ovate and acute, the flowers rose-pink with a greenish

center, 2.5 to 4 Cm. (1 to 1½ In.) broad, the corolla-segments obovate and about twice the length of the corolla.

Other drugs of this family which are worthy of mention are *Exacum Wightianum* Arn. (*Lisianthus Ceylanicus* Spr.; *Exacum C.* Roxb.; *Gentiana trinervis* L.), the *Ginihiringa* of Ceylon; *Slebogtia orientalis* Gris., the *Chhota kirayat*, *Mamijwa*, or *Velluruga*, of India; *Canscora decussata* R. et Sch., largely used in India as a Gentian-substitute and having many native names; *Pleurogyne rotata* Gris. (*Gentiana r.* Froel.; *Swertia r.* L.; *Lomatogonium sulcatum* Reichb.), the Japanese *To-yuk*. Many other species of *Swertia* are similarly employed.

GERANIUM, *U. S.*—Geranium.

Spotted or Wild cranesbill or storksbill, Alum-root, Cranesbill-root, E.; *Racine de geranium maculé, Bec-de-grue tacheté, Pied-de-corneille.* Fr.; *Fleckstorchschnabel*, G.; *Geranio*, Sp.

The dried rhizome of *Geranium maculatum* L. (Fam. *Geraniaceæ*).

Geranium is not elsewhere official.

Fig. 196.

Geranium maculatum: rhizome (Nat.) and transverse section of rhizome and root.

Origin.—A perennial herb, very common and abundant in woodlands throughout eastern and central North America, flowering in late spring and early summer. It is softly hairy, 1 to 2 feet in height, loosely branched above, has very long-petioled radical leaves, those of the stem having successively shorter petioles, the blades rounded, cordate, palmately 5- to 7-lobed, the divisions inversely wedge-shaped, coarsely toothed above, spotted or blotched in late summer. The flowers are of a light violet-purple, 2.5 to 4 Cm. (1 to 1½ In.) broad, slenderly pedicelled, borne in loose umbels, the buds nodding, symmetrically 5-merous with 10 stamens, the 1-seeded pistils adherent for most of their length to a slender carpophore, from which they separate at maturity, except at the top. The drug is commonly collected in late summer or autumn; but the proper time is just previous to the blooming of the plant.

Description.—Of horizontal growth, 5 to 10 Cm. (2 to 4 In.) long and 0.5 to 1.5 Cm. (⅕ to ⅗ In.) thick, more or less crooked, cylindraceous but somewhat vertically flattened, brown; roughly and shortly wrinkled and strongly, rather sharply tuberculate; fracture short, purple, the bark thin, a few short and broad yellowish wood-wedges scattered near the dark cambium; inodorous; taste strongly astringent.

Constituents.—Geranium contains tannin, gallic acid, resin, pectin, sugar, a crystalline principle soluble in alcohol and ether, and geranium-red, a phlobaphene formed from the tannin. Trimble and Peacock, studying the yield of tannin in the different months, found it most abundant in April, and especially before the plant bloomed. From 11.72 per cent. of the absolutely dried drug in January, it increased to 27.85 per cent. in April, and from then steadily dropped till in October there was only 9.72 per cent. It belongs to the gallotannic series, yielding pyrogallol on heating. By the action of heat and hydrochloric acid it is easily decomposed into glucose, gallic acid, and geranium-red. There is no gallic acid in the fresh plant.

Pharmaceutical Preparation.—Fluidextract of Geranium, U. S. P.

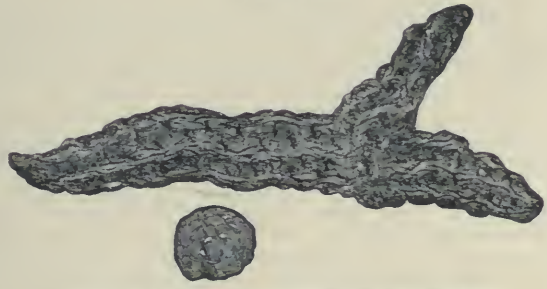
Action and Uses.—Geranium is an astringent, and may be employed in all conditions in which a remedy of this class is serviceable. It is especially useful in infants and in persons who have a delicate stomach, because of its non-irritating properties. Geranium is particularly valuable in serous diarrhœas. It may be tried in the treatment of internal hemorrhages, but is probably of little service unless it comes directly in contact with the bleeding point. A decoction made with 1 ounce (30 Gm.) of the root and 1½ pints (720 Cc.) of water boiled to 1 pint (480 Cc.) may be used as a mouth-wash in aphthous stomatitis, and as a gargle in relaxed conditions of the throat. It may also be used as an astringent injection in the vagina and rectum. The drug has been recommended in prolapsus ani and uteri, but in these conditions it is of little value.

The dose of the powdered rhizome is from 20 to 40 grains (1.3–2.6 Gm.); of the decoction, from 1 to 2 fluidounces (30–60 Cc.); and of the fluidextract, from ½ to 1 fluidrachm (2–4 Cc.).

Allied Drugs.—A number of rhizomes having properties and uses practically identical with those of Geranium may be profitably considered at this point, even though some are not related to it. Not including the closely related Pelargoniums, cultivated in the house and garden under the name of Geranium, the true Geraniums are about 160 in number. Many of them are known to the writer to have rhizomes astringent like our official one and capable of replacing it, and a score or more of species are recorded as being so used, either the rhizomes or herbage, in various parts of the world. *G. Wallichianum* Sweet is said to be used in India as a substitute for alkanna in dyeing. *G. Robertianum* L., the *Herb Robert, Herbe a Robert* (Fr.), *Ruprechtskraut* (G.), is a weak, hairy plant, with pinnatifid leaves, and rose-purple flowers, of Europe and North America. It has a strong, rather unpleasant odor, a bitterish, saline, and astringent taste, and contains tannin and an amaroid. It has been used as a mild astringent and tonic. *Erodium Cicutarium* (L.) L. Her. (*Geranium C.* L.), the *Storksbill, Pin-clover, Pingrass*, or *Alfilaria*, of southern Europe and the Levant, and a pernicious weed of southern South America and western North America, somewhat resembles the last and has a carroty odor when bruised. It has a similar use, as has the *E. moschatum* Ait., with a musky odor. The closely related *Monsonia ovata* Cav., or *Cape geranium*, is used in South Africa precisely as we use Geranium.

Tormentilla, or *Tormentil* (*Septfoil*, E.; *Tormentille*, Fr.; *Tormentillwurzel, Ruhrwurzel, Blutwurzel*, G.), the rhizome of *Potentilla Tormentilla* Neck. (*Tormentilla erecta* L.; *T. officinalis* Curt.; *Potentilla o.* Gray.—Fam. *Rosaceæ*), native of northern Europe and Asia, is very extensively used like our Geranium, and has been official in various pharmacopœias. It is 2.5 to 5 Cm. (1 to 2 In.) long, as thick as the finger or smaller, tapering to one end, usually with 1 to 3 short branches near the larger end, ridged with several strong longitudinal wrinkles, and between them bearing numerous blunt indentations; internally light brownish-red, the fracture short and somewhat resinous, showing a thin bark, 1 or 2 circles of small, yellowish wood-wedges, broad medullary rays, and a large pith. It has a peculiar faint odor and a strongly astringent taste. It contains 18 to 30 per cent. of tannin, 18 per cent. of tormentil-red, a product of the tannin, and yielding with potassium hydroxide protocatechuic acid and phloroglucin. There is also some resin, and ellagic and kinovic acids have been reported. Many others of the 150 species of *Potentilla* have been similarly employed.

Fig. 197.



Tormentilla: rhizome and transverse section (Nat.).

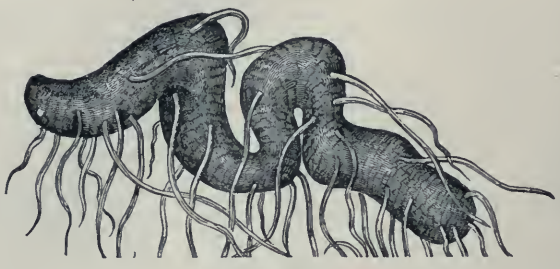
A number of other Potentillas are used partly for their bitter constituents, and will be considered under Rosaceæ. Tormentil possesses aromatic, bitter, and astringent properties, and may be employed for the same purposes as Geranium.

Bistorta, or *Bistort* (*Snakewort, English serpentary, Sweetdock*, E.; *Wiesenknöterich, Natterwurz*, G.; *Bistorte, Couleuvrine*, Fr.), the rhizome of *Polygonum Bistorta* L. (*Bistorta officinalis* Raf.; *B. major* Gray.—Fam. *Polygonaceæ*), has a record very similar to that of the last described. Before the present varied and abundant sources of starch were possessed, it was resorted to for that substance. It is very abundant in swampy meadows in northern Europe and Asia, and is represented in North America by the very similar *P. viviparum* L. (*Bistorta v.* Gray). It is sometimes several inches in length, about ½ inch thick, somewhat flattened vertically, sigmoid-curved (see Fig. 198), more or less annulate and bearing few slender roots, otherwise smooth, dark-purplish or blackish-brown; fracture nearly smooth, reddish or purple, showing a moderately thick bark, numerous small wood-bundles in one circle and a large pith; nearly inodorous and strongly astringent. It contains about 20 per cent. of tannin and a large amount of starch. (Other species of the genus, though containing tannin, are used also for other constituents, and will be considered under Polygonaceæ.)

The North American genus *Heuchera*, L. (Fam. *Saxifragaceæ*), with some 24 species, is noted for its highly astringent rhizomes; and that of *H. Americana* L. (*Split-rock* or *Cliff-weed*), of eastern and central North America, has been very extensively used under the name *Alum-root*. It is a perennial herb, bearing a large radical rosette of orbicular-heart-shaped, slightly lobed, and crenately toothed hairy leaves and very slender glandular hairy scapes

about 60 Cm. (2 Ft.) high, bearing loose panicles of small flowers with short, white, narrow petals and exserted stamens and styles. The rhizome is about 15 Cm. (6 In.) long and about 12 Mm. (½ In.) thick, with several short cylindrical heads terminating with a concave scar, tapering, and somewhat branched below, and beset with some thin roots. In its fresh state it is fleshy; when dry, irregularly shrivelled, tuberculate, the brittle fibers usually broken off. It is externally of a purplish-brown color, has a thin bark, and a thick, fleshy meditullium of a pale-reddish or brownish tint, and breaks with a short somewhat spongy or granular, not fibrous fracture, often showing internal cavities. It is inodorous, and has a strongly astringent, slightly bitterish taste. The roots agree with the rhizome in color and taste, but have a thick bark and a thin, spongy center. Heuchera has not been fully analyzed. It contains from 10 to 20 per cent. of tannin, according to the season, the most in winter.

Fig. 198.



Bistorta (Nat.).

H. villosa Mx., of the southeastern United States, has also been considerably so employed. Bistort has been employed in the treatment of serous diarrhœas and other conditions in which the vegetable astringents are usually recommended.

Statice.—This name applies to drugs derived from a number of species of the genera *Statice*, L., and *Limonium*, Adans. (Fam. *Plumbaginaceæ*), which, rich in tannin, are much used as astringents and styptics. *Limonium Carolinianum* (Walt.) Britton (*Statice C.* Walt.; *S. Limonium* Gray) is the *American marsh rosemary, Canker-root, Meadow-root, Sea lavender, Marsh-root, Thrift, Ink-root*, growing in salt marshes of the Atlantic and Gulf coasts and formerly confused with the European statices and limoniums. The paniculately much-branched scape, with its numerous small, lavender or purplish-blue flowers, rises from a tuft or rosette of spatulate-oblong or oblanceolate, 1-ribbed, bristly pointed leaves. The root is several-headed, 30 to 60 Cm. (1 to 2 Ft.) long, and 2.5 Cm. (1 In.) or more thick at the crown. It is closely annulate above, its stout branches longitudinally wrinkled. It is deep-brownish-purple without, somewhat paler within, tough and compact, with a short fracture, a rather thick bark and a meditullium with narrow pale-yellow wood-wedges. It is nearly odorless, strongly astringent, and slightly bitter. It contains from 12 to 18 per cent. of tannin, reacting greenish-black with ferric salts, a trace of volatile oil, a little caoutchouc-like matter, and gum, and is rich in inorganic salts of sodium and magnesium.

In Brazil, *L. Brasiliensis* (Boiss.) Lyons (*Statice B.* Boiss.) is similarly and very largely employed under the names *Baycuru, Biacuru*, and *Guaycuru*, as is *L. Limonium* (L.) Lyons (*Statice L.* L.; *L. vulgare* Mill.), the *European sea lavender*, etc., *Marsh-beet, Red behen*, E. (*Strandnelke*, G., *Romarin des marais, Lavandetriste*, Fr.), in Europe. Biacuru contains 1.3 per cent. of acrid, pungent resin (Symes), and Dalpe claims to have obtained a small portion of the alkaloid *baycurine*, though the statement does not appear to have been verified. Other names promiscuously applied to the different species are *Cliff rose, Sea cushion*, and *Cushion pink*. The genus Limonium contains about 120 species, and a large number of them appear to be indiscriminately employed for the same purposes. The same is true of a number of the 20 species of *Statice*, L., known by the same common names, especially *S. Armeria* L. (*Armeria vulgaris* Willd.), which grows almost throughout the north-temperate zone. Statice has been recommended as an astringent, hæmostatic, and discutient. In the form of an infusion or decoction, 1 ounce to the pint (30 Gm.–480 Cc.), it has been employed in the treatment of diarrhœa, dysentery, uterine and pulmonary hemorrhages. As a gargle, it may be tried for sore throat, especially where there is much relaxation of the mucous membrane.

GILLENIA.—Gillenia.

Indian physic, Indian hippo, False or North American ipecac, Bowman's root, E.; *Gillenie,* G.; *Gillénie,* Fr.

The dried rhizome and roots of *Porteranthus trifoliatus* (L.) Britton (*Spiræa t.* L.; *Gillenia t.* Moench) and of *P. stipulatus* (Muhl.) Britton (*Spiræa s.* Muhl.; *Gillenia stipulacea* Nutt. —Fam. *Rosaceæ*).

Fig. 199. Fig. 200.

P. stipulacea. *P. trifoliata.*
Gillenia roots (Nat.).

Origin.—Perennial herbs, *P. trifoliatus* confined almost exclusively to the region east of the Alleghenies, from New York southward, *P. stipulatus* extending more to the westward of that range. They grow to a height of 2 or 3 feet, the stems branched and often somewhat tufted. The leaves are alternate, stipulate, nearly sessile, trifoliolate, the leaflets ovate-lanceolate, acuminate, doubly serrate or incised. The white or rosy flowers are in loose corymbs, pedicelled, 5-merous, the calyx tubular, constricted at the throat, the limb 5-cleft. The petals are long, lance-linear, unequal, the stamens 10–15, very short, the carpels 5, coherent at the base, each becoming a 2- to 4-seeded follicle. The stipules of the first-named are small and narrowly linear, those of the second large, ovate-lanceolate, and incised.

Description.—The rhizome of *P. stipulatus*, the one usually sold, is short, nearly horizontal, about 25 Mm. (1 In.) thick, very knotty from the numerous branches and remnants of stems. The larger roots are about 9 Mm. (⅜ In.) thick near the base, tortuous, irregularly branched, the smaller undulated, and knotty or annulated from the semicircular constrictions and transverse fissures of the bark on one side and the depressions on the opposite side. The rhizome and roots of *G. trifoliata* are smaller and less knotty, the roots often smooth or indistinctly annulated, and with few or no transverse fissures. Both have a reddish- or grayish-brown color externally, and are hard and woody, breaking with some difficulty except through the brittle bark. The bark of the rhizome is thin, the wood about eight times thicker, of a whitish color, with several annual rings enclosing a thin pith and traversed by fine medullary rays. The bark of the root is of uneven thickness, in its outer layer brownish-red, the inner layer reddish-white, with numerous minute red resin-dots. The odor is very slight; the taste of the bark is bitter, not unpleasant, exciting the flow of saliva; the wood is tasteless.

The more tortuous roots might easily pass as an adulterant of ipecac, for which they have been used, and which they resemble in properties. They are, however, much tougher and more flexible, the bark only about half as thick relatively to the radius, and the large red resin-dots are distinctive.

Constituents.—The various analyses made of Gillenia have established the presence of starch, tannin, gum, albumin, fat, resin, etc. The bitter principle, *gillenin*, has been obtained, in an impure condition, by W. B. Stanhope (1856) in the form of a whitish powder having a slight odor and a very bitter taste, neutral to test-paper, soluble in water, alcohol, ether, and dilute acids, and colored blood-red by nitric acid. Its watery solution is stated to be precipitated by lead subacetate, tartar emetic, and potassium hydroxide, but not by tannin; ½ grain caused much nausea. It was prepared by washing the alcoholic extract with water, treating the residue with very dilute sulphuric acid, adding magnesia, evaporating, and exhausting the dry mass with alcohol.

P. stipulatus yields 2 glucosides—*gillein*, in white feathery crystals, soluble in water, alcohol, and dilute acids, and *gilléenin*, yellowish, amorphous, faintly tasting at first, afterward very bitter, soluble in water, and very slightly in alcohol and ether.

Action and Uses.—Gillenia is said to resemble ipecac in its mode of action. In large doses it acts as an emetic, and at times also produces purgation. In small doses it is said to be a tonic, and it has been employed to some extent as a mild emetic.

The dose of the powdered root is from 20 to 30 grains (1.3–2 Gm.) as an emetic, and from 2 to 5 grains (0.12–0.30 Gm.) as a tonic.

GLANDULÆ SUPRARENALES SICCÆ, *U. S.*—Desiccated Suprarenal Glands.

Glandes surrénales desséchées, Fr.; *Getrockenete Nebennieren*, G.

The cleaned, dried, and powdered suprarenal glands of the sheep (*Ovis aries*) or ox (*Bos taurus*), freed from fat.—U. S.

The suprarenal capsule is situated over either kidney, and consists of an external cortex of peculiarly arranged cells derived from the mesoblast, and an internal medulla composed of cells derived originally from the sympathetic ganglia. The cortex is apparently without medicinal value, the important physiological properties residing in the medulla.

Preparation.—After removal of the external fat and connective tissue the glands are dried as rapidly as possible in a current of warm air at a moderate temperature, and, when sufficiently dry, are reduced to coarse powder and the remaining fat removed by treatment with petroleum benzin. It is important that all moisture be removed, by exposure in a desiccator if necessary, in order to avoid subsequent putrefaction, after which the residue may be reduced to fine powder, and should be preserved in closely stoppered bottles.

Properties.—A light, yellowish-brown, amorphous powder having a slight, characteristic odor; partially soluble in water. 1 part of desiccated suprarenal glands represents approximately 6 parts of fresh glands, free from fat. Upon incineration it should not yield more than 7 per cent. of ash. If 0.5 Gm. of desiccated suprarenal glands be macerated with 25 Cc. of water for 15 minutes and filtered, the filtrate should give an emerald-green color upon the addition of a few drops of ferric chloride test-solution. The green color disappears quite rapidly.—U. S.

Although the Pharmacopœia states that 1 part of the dried glands represents 6 parts of fresh glands, we have been informed by a large manufacturer that the average yield is 1 part of dried from 5 parts of fresh glands after removal of all fat. The green color developed in the test with ferric chloride solution slowly changes to a brown red or, when viewed through a greater thickness of liquid, to a port-wine color.

Action and Uses.—Dried suprarenal gland has a comparatively limited sphere of usefulness in medicine, having been supplanted almost entirely by adrenalin, or other isolated active principles, which lend themselves to local applications for the arrest of hemorrhage much better than does the dried gland itself. Further than this, it has been found that the administration of the dried gland by the mouth is rarely followed by advantageous results, probably because it is decomposed by the gastric and other digestive juices. Given in this way, it certainly does not produce the effect upon arterial pressure which is caused by the subcutaneous or intravenous injection of adrenalin. The use of the dried gland may be resorted to in certain cases of Addison's disease with the hope that it will hold the disease in abeyance, as it acts as a specific remedy in a very small percentage of these cases. The dose of the dried gland is 3 to 5 grains (0.20–0.30 Gm.), best given in capsule (see ADRENALIN).

GLANDULÆ THYROIDEÆ SICCÆ, *U. S.*—Desiccated Thyroid Glands.

Thyroideum siccum—Dry thyroid, Br.; *Getrockenete Schilddrüsen*, G.

The cleaned, dried, and powdered thyroid glands of the sheep (*Ovis aries*), freed from fat.—U. S.

The thyroid gland is a very vascular organ, situated in front of, and on either side of, the trachea or upper windpipe. It consists of two lobes connected at their upper extremities by a bridge of pale-colored tissue. When freed from all external fat and connective tissue the lobes are broadly almond-shaped, and consist of a firm, succulent mass of tissue with dark-red color.

Preparation.—The British Pharmacopœia gives the following directions: Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after killing. Cut the glands across, and reject any which contain cysts, are hypertrophied, or otherwise abnormal. Mince finely the healthy glands, and dry at a temperature of 32.2° to 37.8° C. (90°–100° F.); powder the dried product; remove all fat from it by treatment with petroleum spirit; and again dry the residue.

It is important that dried thyroid glands be kept in well-stoppered bottles, to avoid absorption of moisture and subsequent deterioration.

Properties.—A yellowish, amorphous powder, having a slight, peculiar odor, and containing the active ingredient of the thyroid tissue; partially soluble in water. 1 part of desiccated thyroid glands represents approximately 5 parts of the fresh glands. Upon incineration it should not yield more than 6 per cent. of ash. If 1 Gm. of desiccated thyroid glands be mixed with an equal weight of pure sodium hydroxide and carefully fused in a silver dish, and oxidized by adding potassium nitrate while fusing, until a white mass remains, and if the fused mass be dissolved in a small quantity of water, the solution treated with 2 Gm. of sodium nitrite, acidified with concentrated nitric acid, and then shaken with 5 Cc. of chloroform, a decided pink to violet coloration should be imparted to the latter (presence of iodine compounds). A cold extract of desiccated thyroid glands treated with 2 Gm. of sodium nitrite and acidified with strong nitric acid should not give the iodine test on shaking with chloroform.—U. S.

The statements of manufacturers differ as to the yield of dried thyroid glands from the fresh, some claiming that after removal of all fat 1 part of the dried glands represents 6 or 7 parts of the fresh glands. The official test for the presence of iodine may be modified with advantage as follows: Mix 1 Gm. of the desiccated thyroid glands with a mixture of sodium carbonate 1 Gm. and potassium nitrate 3 Gm. Fuse in a dish or crucible, allow to cool, dissolve in sufficient distilled water, and transfer to a separator. Add diluted sulphuric acid until the liquid is just acid to litmus-paper, then add 1 drop of fuming nitric acid (or 0.1 Gm. of sodium nitrate), 1 or 2 drops of concentrated sulphuric acid, and also about 3 Cc. of chloroform. Shake the mixture well, allow the liquids to separate, when the chloroform should have a violet tint, due to the iodine extracted from the mass.

The Br. P. describes dry thyroid as a dull-brown powder, with a very faint, meat-like odor and taste, and free from any trace of putrescence.

Action and Uses.—Thyroid gland is one of the most valuable medicinal substances which we possess, and exercises an influence over the processes of nutrition and metabolism which at present is not understood. Indeed, we may be said to be in complete ignorance of the manner in which it exercises its extraordinary influence when administered to man. Given to a healthy individual in moderate amounts, it produces little effect, save that of a circulatory sedative or depressant, and if its use be persisted in it may cause considerable loss of flesh. Its chief value is in the treatment of myxedema, cretinism, and some cases of excessive obesity which are probably closely related to myxedema. Given to cretins, who suffer from absence or atrophy of the thyroid gland, it produces extraordinary changes in their nutrition, and, in a great majority of instances, changes the patient from a condition of dwarfism and idiocy to nearly normal development, and to at least some approximation of ordinary mental power. There is perhaps no more remarkable result of the administration of a properly selected remedy than is seen in the treatment of this malady. A change which is similar in character also occurs in patients suffering from myxedema when thyroid gland is given to them. A normal growth of hair occurs where previously but little remained of the original growth. The broad, spade-like hands return to their natural condition; the mental apathy and stupor is supplanted by ordinary intellectual processes, and the myxedematous condition of the subcutaneous tissues, with its accompanying pallor, is relieved, so that the patient is restored to his natural appearance to so great a degree that but little trace of his ailment remains. Although thyroid gland has been used by many practitioners for the reduction of obesity, it has been by no means constant in its good effects, and when used in sufficiently large doses to cause a distinct loss of weight, it not rarely produces ill-health, and changes the skin from an appearance of health to a sallow hue. Loss of weight under its influence is also not rarely accompanied by marked wrinkling of the skin.

The dose of dried thyroid gland is 1 grain (0.06 Gm.), given in capsule, 3 times a day, which may be gradually increased to 10 or 15 grains (0.6–1 Gm.) a day, but a larger quantity than this should rarely be employed. During the administration of full doses of thyroid gland the patient should remain in bed because of the circulatory depression which sometimes follows its use, and in some cases it is wise to protect the circulation from this depression by the use of moderate doses of strychnine. As the drug not only causes a loss of fat, but also of nitrogenous tissue, patients receiving it in full doses should also partake of a liberal proteid diet. Thyroid gland has been given with asserted success in some cases of primary dementia, and even in acute mania. Its use in exophthalmic goitre is not rational.

GLUCOSUM.—Glucose.

Saccharum amylaceum, Saccharum uveum.—Grape-sugar, Starch-sugar, Dextrose, E.; *Stärkezucker, Traubenzucker, Kartoffelzucker, Glukose, Glykose,* G.

Formula, $C_6H_{12}O_6$. Molecular weight, 178.74.

Chemically the term glucose embraces a number of carbohydrates of the formula $C_6H_{12}O_6$, occurring naturally in plants, or obtained by the action of acids upon starch or cellulose and those organic compounds forming the large class of glucosides, and characterized by a strong reducing action upon Fehling's Solution. Commercially the term glucose is applied to the saccharine product obtained by the inversion of starch, and more particularly to the liquid syrupy form, while to the solidified product the term grape-sugar is applied.

Preparation.—Commercially, glucose is made by boiling 100 parts of starch, 400 parts of water, and ½ to 1¼ parts of sulphuric acid until starch can no longer be detected by means of solution of iodine. The transformation is hastened by heating under pressure in an autoclave. When grape-sugar is to be produced, the inversion of the starch is carried further, so as also to transform most or all of the dextrin to dextrose. Upon completion of the inversion the free acid is neutralized with chalk, and the liquid clarified and decolorized, if necessary, by treating it with clay and animal charcoal, filtering, and concentrating the filtrate in a vacuum-pan to 28°–30° Baumé, at which density much calcium sulphate usually separates and is removed by filtration. The filtrate is further concentrated to 40°–44° Baumé for the liquid *glucose* (*sirop cristal*, Fr.), or crystallized for the solid form, *grape-sugar* (*glucose masse*, Fr.). Liquid glucose (commercially known as glucose, mixing glucose, corn syrup, jelly glucose, confectioners' crystal glucose) is a colorless to light-yellowish, sweetish syrup, of a density 1.40 to 1.43, and contains from 34 to 43 per cent. of dextrose, 0 to 19 per cent. of maltose, 30 to 45 per cent. of dextrin, 14 to 23 per cent. of water, 0.5 to 1.5 per cent. of ash, and a variable percentage of unfermentable carbohydrates, from which Schmitt and Coblenzl separated *gallisin*, $C_{12}H_{24}O_{10}$. Calcium sulphite, added as a preservative, is found in nearly all commercial glucose, and is the cause of the decolorizing action of the latter on solutions containing free iodine.

Grape-sugar is usually in the form of white or whitish to yellowish or even brownish granular masses or powder. It is obtained in crystalline form by the process of A. Behr (1882), by the addition of crystals of dextrose to highly concentrated glucose syrup and allowing to crystallize. Grape-sugar consists of 64 to 99.5 per cent. of dextrose, 0 to 22 per cent. of dextrin, and 0.15 to 0.85 per cent. of ash. The solutions of glucose and grape-sugar usually have a faint acid reaction. Grape-sugar is soluble in a little more than 1 part of water, the fresh solution exhibiting strong birotation, a property which is prevented by the addition of a few drops of ammonia.

Pure dextrose may be obtained in the form of anhydrous crystals by crystallization from alcohol, and as hydrated crystals, $C_6H_{12}O_6 + H_2O$, from less concentrated aqueous solutions. It is a white crystalline powder, of a sweetish taste, but less sweet than cane-sugar or an equal weight of levulose, and is soluble in 1⅓ times its weight of cold water and in about 50 parts of cold or 4.5 parts of boiling alcohol; it is insoluble in chloroform and ether. Some of the commercial "corn-sugar" is practically pure dextrose. Dextrose melts at 146° C. (294.8° F.); at 170° C. (338° F.) it suffers decomposition to glucosan, $C_6H_{10}O_5$, and at still higher temperatures it yields caramel. The hydrated variety loses its water of crystallization below 100° C. (212° F.). Dextrose is strongly dextrorotatory, $[a]_d = 52.7$, from which fact it takes its name. Nascent hydrogen converts it into *sorbite* or sorbitol, $C_6H_8(OH)_6$, an alcohol of which glucose is the aldehyde. Nitric acid oxidizes it to saccharic, tartaric, racemic, and oxalic acids. *Saccharic* acid, $H_2C_6H_8O_8$, is amorphous, deliquescent, freely soluble in water and alcohol, and yields mostly crystallizable salts. Dextrose is directly fermentable. Its solution heated with alkali hydroxide acquires a dark color (distinction from cane-sugar). With organic acids it combines to form oily or amorphous products sparingly soluble in water, but soluble in alcohol and ether. It acts as a strong reducing agent in alkaline solutions. Its aqueous solution is not precipitated by neutral or basic solution of lead acetate, but is precipitated by an ammoniacal solution of lead acetate. It gives the general reactions noted below under *Sugar Tests.*

Pharmaceutical Preparation.—Syrup of Glucose, Br.

Levulose also known as fruit-sugar, an isomer of dextrose, frequently accompanies grape-sugar in fruits, and with dextrose is the principal saccharine matter of honey. In some plants it is associated with cane-sugar. Unlike dextrose, it is not formed by the action of acids upon glucosides, but is produced with dextrose by the inversion of cane-sugar. It is obtained from inulin by treatment with dilute acids. It may be prepared by cooling 10 parts of invert sugar dissolved in 100 parts of water to 0° C. (32° F.) and adding under constant stirring 6 parts of powdered slaked lime. The difficultly soluble *calcium levulosate*, $CaO.C_6H_{12}O_6.H_2O$, soluble in about 325 parts of water, is precipitated, removed by filtration, and washed with ice-cold water to wash out the soluble dextrose compound. The washed precipitate is suspended in water and the calcium removed by precipitation with a current of carbon dioxide. The filtrate is concentrated in vacuum to recover the levulose.

Levulose is usually in the form of a colorless uncrystallizable syrup, but may be obtained in the form of fine silky needles, readily soluble in water and dilute alcohol, soluble in absolute alcohol. It has about the sweetness of cane-sugar. It is strongly lævorotatory, $[\alpha]_d = -98.8°$ at 15° C. (59° F.), the rotation being strongly affected by change in temperature, decreasing by 0.6385 degree for each increase of 1 degree C. It is directly fermentable in aqueous solution, and like dextrose has a powerful reducing action in alkaline solution upon salts of copper, silver, and gold.

Dextrose, levulose, and glucose are distinguished from cane-sugar, or detected in solutions by the following tests; tannin and similar compounds which are likely to interfere are previously removed, either by solvents or precipitants:

Sugar Tests.—*Moore's Test.*—A solution of cane-sugar, heated with 3 or 4 per cent. of potassa for a minute or two, remains colorless; glucose and milk-sugar are colored brown.

Trommer's Test.—A solution of cane-sugar, mixed with a little copper sulphate and an excess of potassa or soda, retains its blue color on boiling, but turns bright-red in the presence of glucose or milk-sugar, red cuprous oxide being deposited. Glucose and most allied sugars effect the same reduction, though more slowly, in the cold.

Fehling's test is a modification of the preceding, and may be used for the quantitative determination of glucose. The test-liquid is prepared by dissolving 34.64 Gm. of crystallized copper sulphate in water, adding 200 Gm. of Rochelle Salt, and 600 or 700 Gm. of sodium hydroxide solution specific gravity 1.20, and diluting the whole to 1 liter (Schorlemmer). 10 Cc. of this solution are reduced by 0.5 Gm. of grape-sugar. Boedecker introduced Rochelle Salt in place of potassium tartrate, which was used by Fehling. The test is usually made with a solution containing about 1 per cent. of glucose; weaker solutions reduce a somewhat smaller amount of the test-liquid.

Since Fehling's Solution is reduced also by dextrin and by milk-sugar, *Barfoed's Solution* (crystallized cupric acetate, 13.3 Gm.; glacial acetic acid, 2 Gm.; distilled water, 200 Cc.), which is not affected by these two substances, is to be preferred for detecting glucose.

Pettenkofer's Test.—Bile in the presence of sugar (of other carbohydrates and of proteids) acquires a blood-red color with concentrated sulphuric or phosphoric acid.

Boettger's Test.—A little bismuth subnitrate boiled with solution of glucose, rendered alkaline by sodium carbonate, acquires a gray or black color; pure cane-sugar produces no alteration.

O. Schmidt's Test.—Lead acetate, added to a saccharine liquid, is precipitated white by excess of ammonia; on heating the mixture it remains unchanged if cane-sugar or milk-sugar is present, but turns orange-red with glucose.

Sachsse's Test.—18 Gm. of mercuric iodide, 25 Gm. of potassium iodide, and 80 Gm. of caustic potassa are dissolved in distilled water sufficient to make 1 liter. 40 Cc. of this solution heated to boiling are decomposed by 1.1342 Gm. of glucose, so that a drop of liquid is not rendered black by ammonium sulphhydrate.

Maumené's Test.—On heating a solution of glucose with a few drops of solution of silver nitrate the liquid acquires a brown color.

Tollen's Test.—An ammoniacal solution of silver nitrate containing caustic soda is reduced by glucose, with the production of a metallic mirror.

Gawalowski's Test.—A solution of sugar heated with neutral ammonium molybdate to 100° C. (212° F.) becomes blue in the presence of glucose.

Action and Uses.—Glucose is quite readily digested, and because of this fact is said to be nearly equal in value to cane-sugar as a food. As it lacks sweetness, however, it is never employed as a sweetening agent. Glucose is reputed to have diuretic properties, and in doses of 6 fluidounces (180 Cc.) daily has been recommended in the treatment of dropsical effusions. It should not be employed where renal changes are marked.

GLYCERINUM, *U. S., Br., P. G.*—Glycerin; Glycerol.

Glycerine, Glycerol, E.; *Glycérine,* Fr.; *Glycerin, Glyceryloxyhydrat, Oelsüss, Scheele'shes Süss,* G.

Formula, $C_3H_5(OH)_3$ or $CH_2OH.CHOH.CH_2OH$. Molecular weight, 91.37.

A liquid sweet soluble principle obtained from fats and fixed oils, and containing not less than 95 per cent. of absolute glycerin, the trihydric alcohol, $C_3H_5(OH)_3$.

Glycerin was discovered by Scheele (1779) in the preparation of lead plaster from olive oil and litharge, and called the *sweet principle of oils.* It occurs as a constituent (4–7 per cent.) of fixed oils and fats, being in combination with the fatty acids as compound ethers or glycerides. It is formed in small quantities, about 3 per cent. of the glucose present, during the fermentation of saccharine liquids, and has been prepared synthetically from tribromo- and trichloropropane.

Preparation.—Glycerin is obtained commercially by the decomposition of animal and vegetable fats and oils by saponification with caustic alkalies as a by-product in the manufacture of soap; by decomposition of the fats in an autoclave by means of steam and a small proportion of lime (Milly), or zinc oxide (Michaud Frères); by saponification with superheated steam at a temperature of 310°–315° C. (590°–599° F.) (Wilson); by decomposing the fats by means of water at a high temperature and pressure (R. A. Tilghman, 1854); and to some extent by decomposing the fats with sulphuric acid and steam in an autoclave.

The best results in the manufacture of glycerin are those obtained by what is known as "aqueous saponification." This process consists in mixing the fats with certain proportions of water in large copper digesters provided with stirrers, and then treating the mixture with superheated steam at a pressure of 8 or 10 atmospheres (120–150 pounds); the temperature is maintained at about 200° C. (392° F.), and the mixture kept in constant motion. This treatment decomposes the fat into glycerin and free fatty acids; the glycerin dissolves in the water and the non-volatile acids float on the surface of the aqueous solution and may be removed mechanically, while the volatile acids are allowed to escape with steam through a small orifice in the top of the digester. The dilute solution of glycerin is transferred to evaporating tanks and concentrated until it reaches a density of 28° Baumè, after which the crude dark amber-colored glycerin is introduced into specially constructed stills, into which steam enters at a temperature of about 250° C. (482° F.), and carries the glycerin in the form of vapor over into a series of condensers so arranged that the first condenser, being least cooled, will contain the heaviest glycerin, the distillate becoming gradually weaker, until in the last condenser almost pure water is collected. Coloring-matter is removed by treatment with animal or vegetable charcoal, and the distillation is repeated two or three times until the required degree of purity has been obtained.

The reaction for a fat like stearin is illustrated by the equation: $C_3H_5(C_{15}H_{35}O_2)_3$ (stearin) + 3(H.OH) (water) = $C_3H_5(OH)_3$ (glycerin) + $3HC_{15}H_{35}O_2$ (stearic acid).

Synthetic or artificial glycerin has been prepared from tribromopropane, $C_3H_5Br_3$, and also trichloropropane, $C_3H_5Cl_3$; the former compound is treated with silver acetate, and the resulting glyceryl acetate or triacetin is decomposed by potassium hydroxide, yielding glycerin and potassium acetate; thus, $C_3H_5Br_3 + 3AgC_2H_3O_2 = C_3H_5(C_2H_3O_2)_3 + 3AgBr$, and $C_3H_5(C_2H_3O_2)_3 + 3KOH = C_3H_5(OH)_3 + 3KC_2H_3O_2$. When trichloropropane is heated with water to 180° C. (356° F.) it also yields glycerin.

In subjecting soap-liquors to dialysis the glycerin passes quite freely with the salts through parchment-paper, but not through "gutta-percha paper," which has been (1882) recommended for the purification of such impure glycerin. The process of purification of glycerin by distillation was patented by Wilson and Payne in 1854.

The world's production of glycerin amounts to over 40,000 tons annually, of which amount about five-eighths is produced in the manufacture of stearic acid and the remainder from soap-liquors. Glycerin was first manufactured in the United States by Robert Shoemaker, at Philadelphia, in 1846. The production in the United States is now estimated at 6000 tons, and the importations at about a like amount per annum.

Properties.—Absolute glycerin is a colorless, odorless, viscid, very hygroscopic, optically inactive, crystallizable liquid, having a sweet and warm (due to absorption of water) taste, and a density of 1.2665 (Allen) at 15° C. (59° F.). It congeals to a crystalline mass at —8° C. (17.4° F.) if shaken, forming hard and very deliquescent crystals. It boils at 290° C. (554° F.), the boiling-point being rapidly lowered through

the presence of water, and may be distilled under reduced pressure without decomposition.

Commercial and pharmacopœial glycerin contain water. The pharmacopœias require glycerin to have a density of 1.230–1.235, P. G., not less than 1.246 at 25° C. (77° F.), U. S., 1.260, Br., which, according to the following by A. B. Lyons, based on the data obtained by W. Lenz (1880), corresponds to 86–97 per cent. of absolute glycerin:

100 per ct.,	1.26596	sp. gr.	91 per ct.,	1.24217	sp. gr.	82 per ct.,	1.21766	sp. gr.	45 per ct.,	1.11618	sp. gr.
99 "	1.26335	"	90 "	1.23945	"	81 "	1.21493	"	40 "	1.10253	"
98 "	1.26072	"	89 "	1.23673	"	80 "	1.21221	"	35 "	1.08908	"
97 "	1.25809	"	88 "	1.23400	"	75 "	1.19857	"	30 "	1.07564	"
96 "	1.25547	"	87 "	1.23128	"	70 "	1.18487	"	25 "	1.06236	"
95 "	1.25285	"	86 "	1.22855	"	65 "	1.17113	"	20 "	1.04930	"
94 "	1.25021	"	85 "	1.22583	"	60 "	1.15737	"	15 "	1.03652	"

92 "	1.24487	"	83 "	1.22038	"	50 "	1.12990	"	5 "	1.01189	"

Pharmacopœial glycerin is a clear, colorless, odorless, neutral liquid, of a thick, syrupy consistence, oily to the touch, very sweet and slightly warm to the taste, and miscible in all proportions with water or alcohol. It is soluble in a mixture of 3 parts of alcohol and 1 part of ether, or in a mixture of equal weights of chloroform and alcohol (useful in separating from gum, sugar, and gelatin). It is insoluble in ether, benzin, benzene, carbon disulphide, chloroform, and fixed or volatile oils. It dissolves bromine, iodine, sulphur .iodide, salicin, santonin, sugar, gum, pepsin, tannic acid, deliquescent salts, increases the solubility of many organic compounds which are soluble in water or alcohol, and prevents the precipitation of some salts by alkalies and other reagents. Exposed to the air, it slowly absorbs moisture, which under favorable conditions may amount to twice (W. Willmott) the bulk of the glycerin. It is slowly volatilized from an aqueous solution, at or above 100° C. (212° F.), with the vapor of water. Heated by itself to a high temperature it yields acrid fumes containing *acrolein*, boils at or above 165° C. (329° F.), and is ultimately decomposed and dissipated. With water under pressure it may be distilled without decomposition at 170°–260° C. (338°–500° F.). It may be cooled to −35° C. (−31° F.) without freezing; even with 28 per cent. of water it will bear a temperature of −31° C. (−23.8° F.) for a time without congealing. At −40° C. (−40° F.) glycerin becomes a gummy mass.

Chemically, glycerin is a triatomic alcohol and known as propenyl alcohol; hence chemists often designate it *glycerol*, in analogy with other alcohols. It forms with acids three series of ethers, in which 1, 2, or 3 atoms of hydrogen are replaced by the corresponding number of univalent acidulous radicals. The so-called neutral fats are compound ethers or ethereal salts, like *tripalmitin*, $C_3H_5(C_{16}H_{31}O_2)_3$. A similar compound is *glyceryl trinitrate*, also known as *nitroglycerin* or *glonoin*, $C_3H_5(NO_3)_3$ (which see).

When 1 part of glycerin is heated with 2 parts of acid potassium sulphate, 2 molecules of water are split off and the glycerin is converted into *acrolein* or *allyl aldehyde*; thus, $C_3H_5(OH)_3 - 2H_2O = C_3H_4O$; the same effect is produced when glycerin is heated with an excess of phosphoric anhydride, or even rapidly heated by itself to a temperature of about 290° C. (554° F.). Acrolein is a light, very refractive, and volatile oily liquid, the vapors of which are extremely irritating to the eyes.

Glycerin dissolved in water and kept, with yeast, at a temperature of about 25° C. (77° F.), is converted into *propionic acid*, and with chalk and old cheese at 40° C. (104° F.) it yields *alcohol* and *butyric acid*. When slightly diluted with water and heated to just above 100° C. (212° F.) in the presence of oxalic acid, the latter will be decomposed into *carbon dioxide* and *formic acid*. $C_2H_2O_4$ yields $CO_2 + CH_2O_2$; the formic acid may be afterward obtained by *repeatedly* diluting with water and distilling. Glycerin unites with the alkalies and alkaline earths to form compounds soluble in water, the former also in alcohol; the latter are not precipitated by carbonic acid. It unites also with sulphuric and other acids. If a fused bead of borax on a loop of platinum wire be moistened with glycerin and then held in a colorless flame, the latter will be transiently tinted deep-green.—U. S. This behavior was observed by Iles (1877), and recommended as a test for borates or for glycerin, but Klein (1878) showed that the reaction with borax takes place not only with glycerin, but also with other polyhydric alcohols; and the conditions for these reactions have been elaborately investigated by Dunstan (1883), proving that sodium pyroborate is decomposed, with the formation of sodium metaborate and a boric ether, or, if water be present, free boric acid, the alcohol being regenerated.

Tests.—Glycerin is now rarely adulterated, but since much is prepared for uses in the arts, where purity is not necessary, impure glycerin may at all times be met with in the market. Water, mucilage, dextrin, glucose, and perhaps cane-sugar syrup, would be used as adulterants. The first is detected by the specific gravity of the sample, the others by the brown color produced on mixing the sample with twice its bulk of concentrated sulphuric acid. Since cane-sugar syrup which has been exposed to the light for some time contains appreciable quantities of glucose, glycerin adulterated with either kind of sugar will become brown on being heated with solution of potassium or sodium hydroxide, and will yield a red precipitate when heated to boiling with a drop of solution of copper sulphate and an excess of potassa. The impurities may consist of saline matters should the glycerin have not been distilled, of odorous compounds if insufficiently purified by distillation, or arsenic from the use of impure sulphuric acid made from pyrites. The odor becomes apparent on warming the glycerin or rubbing it well upon the hand. Most of these compounds reduce silver nitrate and produce a more or less deep color when glycerin is diluted with a little distilled water and, after the addition of a few drops of silver nitrate solution, heated to boiling. The same reagent will detect chlorides by the white precipitate produced. Diluted glycerin should not be colored or rendered turbid on being tested with hydrogen sulphide or ammonium sulphide (metallic salts), ammonium oxalate (calcium), or barium chloride (sulphuric or oxalic acid). The presence of butyric acid is readily determined by warming a mixture of glycerin with one-fourth its measure each of alcohol and sulphuric acid, when butyric ether, recognized by its odor of pineapple, will be given off. The most important tests for practical purposes are those with sulphuric acid and silver nitrate. Goddefroy (1874) recommended the heating of glycerin in an open crucible to boiling, and then igniting it, when it should burn without diffusing the least smell or leaving the least residue. From these reactions the following tests have been formulated: "5 Cc. of glycerin, heated to boiling in an open porcelain or platinum dish, and then gently ignited, should burn and vaporize, so as to not leave more than a dark stain, which on stronger heating should disappear entirely (absence of mineral impurities). If 5 Cc. of glycerin be mixed with 50 Cc. of water and 10 drops of hydrochloric acid in a small flask, and heated for half an hour on a water-bath to boiling, then 10 Cc. of the hot liquid, mixed with 2 Cc. of sodium hydroxide test-solution and 1 Cc. of alkaline cupric tartrate volumetric solution, should show no yellowish-red cloudiness or precipitate within 6 hours (absence of sugars). If 5 Cc. of glycerin be mixed with an equal volume of concentrated sulphuric acid in a test-tube, the liquid should acquire a color not darker than yellow on standing for 1 hour (absence of readily carbonizable impurities). If 5 Cc. of glycerin be mixed with the same volume of a mixture of equal parts of alcohol and diluted sulphuric acid and gently heated, a fruity odor should not be recognizable (absence of butyric acid). No color, cloudiness, or precipitate should appear when separate portions of its aqueous solution (1 in 10) are treated with barium chloride test-solution (sulphuric acid); calcium chloride test-solution (oxalic acid); ammonium oxalate test-solution (calcium salts); silver nitrate test-solution (chlorides); or silver ammonium nitrate test-solution (acrolein); in the last-mentioned case the test-tube, loosely stoppered to protect it from impurities, should be allowed to stand at least 5 minutes. 5 Cc. of an aqueous solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic (see Arseni Trioxidum). The aqueous solution (1 in 20), when acidified with hydrochloric acid, and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen sulphide test-solution after standing, well stoppered, in a warm place, 35° C. (95° F.), for at least ½ hour, nor should the further addition of ammonia-water to this solution cause a coloration or turbidity therein (absence of heavy metals.)."—U. S. If a mixture of 1 Gm. of glycerin and 1 Cc. of ammonia be heated to 60° C. (140° F.) and at once treated with 3 drops of solution of silver nitrate, no discoloration or brown precipitate should result within 5 minutes. 1 Cc. of glycerin heated with 1 Cc. of sodium hydroxide solution should not become discolored, nor develop an odor of ammonia or glue. 1 Cc. of glycerin mixed with 3 Cc. of stannous chloride solution should not become colored within one hour (absence of arsenic).—P. G. 2 Cc. diluted with 5 Cc. of a mixture of 1 part of hydrochloric acid and 7 parts of water, 1 Gm. of pure zinc being added, and the whole placed in a long test-tube, the mouth of which is covered by a piece of filter-paper moistened with a drop or two of test-solution of mercuric chloride and dried, should not afford a yellow stain on the paper even after 15 minutes (limit of arsenic).—Br.

Pharmaceutical Uses.—Glycerin forms the base of the official *glycerita* (*glycerina*), and glycerin suppositories, and is a constituent of a number of official fluidextracts, tinctures, and syrups; also of Mucilago Tragacanthæ, U. S. It is used for preserving pill-masses and certain extracts in a plastic condition, and for preventing fermentation and other changes in aqueous liquids containing organic matter in solution.

Action and Uses.—Glycerin is a mild laxative, and may be employed either by the mouth or rectum in the treatment of simple constipation. A glycerin enema containing from 2 to 4 fluidrachms (8–16 Cc.) of the drug diluted with an equal amount of water, or the official suppository, may be used. It should be remembered, however, that the continued use of this remedy may cause rectal irritation. If given in large amounts, it produces dryness of the mucous membranes, loss of muscular strength, considerable mental depression, and collapse. If injected directly into the circulation, it may also produce convulsions because of its hygroscopic action upon the blood. Glycerin is rarely administered internally except in the treatment of constipation. It may be employed as a demulcent, and as a vehicle for many disagreeable remedies. The remedy has also been recommended as a substitute for codliver oil, but it is inferior to the latter in the treatment of pulmonary tuberculosis. It is both affirmed and denied that glycerin may be used as a substitute for sugar in dieting diabetic patients, and as saccharin is much better, glycerin receives little consideration. Diluted with 4 parts of water and applied to the nostrils, it is sometimes useful in the early stages of acute coryza. Equal parts of glycerin and water flavored with a small quantity of lemon juice form an excellent remedy for removing sordes in enteric fever, and for preventing dryness of the mouth in advanced tuberculosis. An excellent preparation prepared by heating 1 part of potato starch with 15 parts of glycerin may be employed locally in the treatment of eczema, psoriasis, herpes, lichen, and chapped skin. Its local application is also said to prevent bedsores, and when applied upon a tampon it is a most valuable remedy for the relief of pelvic inflammation and congestion of the uterine cervix. This remedy is also employed in the external auditory canal for the purpose of softening impacted cerumen. The dose by the mouth as a laxative is from 1 to 2 fluidrachms (4–8 Cc.), and when given by the rectum from 1 fluidrachm to a tablespoonful (4–16 Cc.).

Derivative Products.—DICHLORHYDRIN. *a*-Dichlorhydrin. Formula, $C_3H_6Cl_2O$. Molecular weight, 127.97.—Dichlorhydrin is prepared by heating anhydrous glycerin with 2½ parts of sulphur monochloride, the following reaction taking place: $C_3H_8O_3 + 4SCl = C_3H_6Cl_2O + 2HCl + 3S$. It is a colorless, odorless, viscid liquid, soluble in 10 volumes of water, boils at 176° C. (348.8° F.), and has a specific gravity of 1.364 at 15° C. (59° F.). Dichlorhydrin is a good solvent of resins. Amber is soluble in 10 parts, and copal in apparently all proportions of dichlorhydrin. It is an excellent solvent of nitrated cellulose, and may find extensive use in the arts. It destroys India-rubber and cork stoppers.

EPICHLORHYDRIN. Formula, C_3H_5ClO. Molecular weight, 91.79.—Prepared by heating 2 parts of dichlorhydrin and 1 part of powdered sodium hydroxide to not over 130° C. (226° F.). It is a colorless limpid liquid having a chloroform-like odor, specific gravity 1.191 at 15° C. (59° F.), boils at 117° C. (242.6° F.), and possesses the general solvent properties of dichlorhydrin. By the action of potassium hydroxide upon epichlorhydrin various ethers of glycerol are produced. (Zunino, *J. C. S.*, 1900, A. 1, p. 535.)

GLYCERITA.—Glycerites—GLYCERINA.—Glycerins.

Glycerata, Glycerolata.—Glycerols, E.; *Glycérés, Glycérats, Glycérolés*, Fr.; *Glycerite, Glycerolate*, G.

This class of preparations, first proposed in 1854 by Cap and Garot, has met with much favor here and abroad. They are easily prepared, and keep indefinitely if protected against absorption of moisture from the air. The name glycerites, as applied to these solutions, seems preferable to the British term glycerins.

GLYCERITUM ACIDI TANNICI, *U. S.*—Glycerite of Tannic Acid.

Glycerinum acidi tannici, Br.; *Glycerin of tannic acid* (*of tannin*), E.; *Glycéré de tannin, Glycérine tannique*, Fr.; *Tannin-Glycerit*, G.

Preparation.—Tannic acid, 20 Gm.; glycerin, 80 Gm.; to make 100 Gm. Triturate the tannic acid with the glycerin to a smooth paste, transfer this to a tared porcelain capsule, avoiding contact with metallic utensils, and apply the heat of a water-bath until the acid is completely dissolved.—U. S.

(480 grains of tannic acid may be dissolved in 27 fluidrachms of glycerin.)

Take of tannic acid, 1 ounce; glycerin, sufficient to produce 5 fluidounces. Rub them together until solution is effected.—Br.

Action and Uses.—Because of its greater solubility glycerite of tannic acid is largely employed for its local effect. It may be used both internally and externally for the various conditions in which ACIDUM TANNICUM (which see) is employed. The internal dose is from 10 to 30 minims (0.6–2 Cc.), well diluted.

GLYCERITUM ALUMINIS.—Glycerite of Alum.

Glycerinum Aluminis, Br.—*Glycerin of alum*, E.; *Glycéré d'alun*, Fr.; *Alaun-Glycerit*, G.

Preparation.—Take of alum, in powder, 1 ounce; distilled water, 3 fluidrachms; glycerin, sufficient to produce 6 fluidounces. Triturate until solution is effected, warming slightly if necessary; set aside; pour off the clear liquid from any deposited matter that may be present.—Br.

Action and Uses.—This preparation possesses the same properties and uses as ALUMEN (which see). It is employed externally and only for its astringent effect.

GLYCERITUM AMYLI, *U. S.*—Glycerite of Starch.

Glycerinum amyli, Br.; *Unguentum glycerini*, P. G.—*Glycerin of starch, Glycamyl, Plasma*, E.; *Glycéré d'amidon, Glycérat simple (d'amidon)*, Fr.; *Glycerinsalbe*, G.

Preparation.—Starch, 10 Gm.; water, 10 Cc.; glycerin, 80 Gm. Triturate the starch with the water until a homogeneous mixture is produced. Then gradually add this to the glycerin, contained in a porcelain dish, and heated to about 140° C. (284° F.). Continue the heat, with constant stirring, keeping it below 144° C. (291.2° F.), until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers.—U. S.

Starch, 1 ounce; glycerin, 6½ fluidounces; distilled water, 1½ fluidounces. Stir and heat.—Br.

Wheat starch, 10 parts; water, 15 parts; glycerin, 90 parts. Mix the starch and water, add the glycerin, and heat the mixture on a boiling water-bath until a translucent jelly results.—P. G.

Starch, 1 part; glycerin, 14 parts. Heat carefully.—Fr. Cod.

This preparation was introduced into British pharmacy by G. F. Schacht in 1858, and soon after became known in the United States. To obtain a uniform jelly-like mass, the starch should be first rubbed into a fine powder free from lumps, then intimately mixed with the glycerin and water, which may be done in the porcelain capsule, thus avoiding the unavoidable loss when done in a mortar; and finally the mixture is heated until all starch-granules are ruptured and the liquid is thickened to a translucent mass free from white spots. Prepared in this manner, the glycerite must be preserved in well-stoppered bottles, for in contact with the air it attracts moisture and gradually becomes soft. This tendency is entirely removed, according to W. Willmott (1879), by substituting for one-third of the glycerin an equal measure of water.

Action and Uses.—Glycerite of starch is an emollient. It may be locally applied for its soothing effect in cases of burns, erythematous and erysipelatous inflammations. Its local application will also remove excessive quantities of iodine which have been accidentally applied to the skin.

GLYCERITUM BORACIS.—Glycerite of Borax.

Glycerinum boracis, Br.—*Glycerin of borax*, E.; *Glycéré de borax*, Fr.; *Borax-Glycerit*, G.

Preparation.—Take of borax, in powder, 1 ounce; glycerin, 6 fluidounces. Triturate the borax with the glycerin until solution is effected.—Br.

From the investigations of W. R. Dunstan, it appears that this preparation will contain some free boric acid.

Action and Uses.—Because of its agreeable taste this preparation is suitable for the employment of borax in the treatment of thrush, aphthous stomatitis, and other inflammatory conditions of the mouth. It may also be used locally in the treatment of erysipelas and pityriasis.

GLYCERITUM BOROGLYCERINI, *U. S.*—Glycerite of Boroglycerin.

Glycerinum acidi borici, Br.—*Glycerin of boric acid, Glycerite of glyceryl borate, Solution of boroglyceride*, E.; *Glycéré (Soluté) de boroglyceride*, Fr.; *Boroglycerid-lösung*, G.

Preparation.—Boric acid, in powder, 310 Gm.; glycerin, a sufficient quantity to make 1000 Gm. Heat 460 Gm. of glycerin in a tared porcelain capsule to a temperature not exceeding 150° C. (302° F.), and add the boric acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring and breaking up the film which forms on the surface. When the mixture has been reduced to the weight of 500 Gm., add to it 500 Gm. of glycerin, mix thoroughly, and transfer it to suitable vessels.—U. S.

1 pint of this solution, containing 50 per cent. by weight of boroglycerin, weighs about 23 avoirdupois ounces (22.7544), and hence may be prepared by heating 4600 grains of glycerin with 3100 grains of boric acid at the above-mentioned temperature until the mixture weighs 5000 grains, and then adding an equal weight of glycerin. (10,000 grains = 22.85 avoirdupois ounces.) When glycerin and boric acid are heated together for some time, chemical union takes place, with the elimination of aqueous vapor, and, according to Dr. James, the reaction may be illustrated as follows: $C_3H_5(OH)_3$ (glycerin) + H_3BO_3 (boric acid) = $C_3H_5BO_3$ (boroglycerin) + $3H_2O$ (water). Care must be observed not to exceed the prescribed temperature, lest the product become discolored (yellowish or even darker). Attention was first called to boroglyceride and its remarkable preservative properties by F. S. Barff in 1881. The preparation of the Br. P. is practically identical with the preceding in strength, and is made in the same manner. 6 ounces of boric acid and 9 ounces of glycerin are heated together until reduced in weight to 10 ounces, when 10 ounces more of glycerin are added.

Action and Uses.—This preparation is used locally in medicine as a dipletant in congestion of the cervix uteri, being placed on a cotton tampon.

GLYCERITUM FERRI QUININÆ ET STRYCHNINÆ PHOSPHATUM, *U. S.*—Glycerite of the Phosphates of Iron, Quinine, and Strychnine.

Glycéré des phosphates de fer, de quinine et de strychnine, Fr.; *Eisen-, Chinin-, und Strychninphosphat-Glycerit*, G.

Preparation.—Soluble ferric phosphate, 80 Gm.; quinine, 104 Gm.; strychnine, 0.8 Gm.; phosphoric acid, 200 Cc.; glycerin, 500 Cc.; water, a sufficient quantity to make 1000 Cc. Heat the soluble ferric phosphate with 200 Cc. of water, in a porcelain dish, at a temperature not exceeding 70° C. (158° F.), until it is dissolved. Then add the phosphoric acid with the quinine and strychnine and sufficient water to make the product measure 500 Cc., and stir until solution is effected. Mix the solution with the glycerin, and filter if necessary.—U. S.

To prepare 1 pint of this glycerite, dissolve 572 grains of soluble ferric phosphate in 3 fluidounces of water with the aid of heat; then add to the solution 3 fluidounces and 80 minims of phosphoric acid together with 746 grains of quinine alkaloid, 6 grains of strychnine, and sufficient water to make the product measure 8 fluidounces. To this solution add 8 fluidounces of glycerin and mix thoroughly.

Glycerite of the phosphates of iron, quinine, and strychnine is one of the new preparations of the Pharmacopœia, and was introduced for the purpose of extemporaneously making the well-known syrup of the same name, and thereby avoiding the annoying discoloration which invariably occurs when saccharine solutions are allowed to stand in the presence of acids for some time. It is a pale amber-colored fluorescent liquid, which darkens but very slightly even when kept on hand in diffused light for a long time, and has a very acid bitter taste. It contains 0.08 Gm. of iron phosphate in each cubic centimeter, together with 0.104 Gm. of quinine and 0.0008 Gm. of strychnine, both present as phosphates, or in each teaspoonful $4\frac{1}{2}$ grains of iron phosphate, $6\frac{1}{5}$ grains of quinine, and about $\frac{1}{22}$ grain of strychnine. When mixed with simple syrup in the proportion of 1 volume of glycerite and 3 volumes of syrup, it corresponds with the official Syrupus Ferri Quininæ et Strychninæ Phosphatum (which see).

Action and Uses.—The chief employment of this preparation is in the manufacture of the syrup. It may be administered for the same conditions in which the syrup is employed. (See Syrupus Ferri, Quininæ et Strychninæ Phosphatum.) The dose is from 15 to 60 minims (1–4 Cc.).

GLYCERITUM HYDRASTIS, *U. S.*—Glycerite of Hydrastis.

Glycéré d'hydrastis du Canada, Fr.; *Gelbwurzel-Glycerit*, G.

Preparation.—Hydrastis, in No. 60 powder, 1000 Gm.; glycerin, 500 Cc.; alcohol, water, each a sufficient quantity to make 1000 Cc. Moisten the hydrastis with 350 Cc. of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow percolation to proceed slowly, gradually adding alcohol, until the hydrastis is practically exhausted. Remove nearly all of the alcohol by distillation or evaporation, pour the thick concentrated liquid into 500 Cc. of ice-cold water, and set it aside in a cold place for 24 hours. Then filter, pass enough cold water through the filter to make the filtrate measure 500 Cc., add the glycerin, and mix thoroughly.—U. S.

25 avoirdupois ounces of hydrastis should be moistened with about 9 fluidounces of alcohol, and percolated to exhaustion with the same menstruum; after nearly all the alcohol has been evaporated, the thick liquid is poured into 12 fluidounces of ice-cold water and set aside for 24 hours. The mixture is then filtered and sufficent water passed through the filter to bring the volume up to 12 fluidounces, and lastly 12 fluidounces of glycerin are added and the whole thoroughly mixed.

Glycerite of hydrastis is chiefly intended to furnish a fluid preparation of hydrastis which shall be miscible with water in all proportions without precipitation. Each Cc. represents 1 Gm. of hydrastis, or a fluidounce, about 463 grains.

Action and Uses.—The properties of the preparation are considered under HYDRASTIS (which see).

GLYCERITUM PEPSINI.—Glycerite of Pepsin.

Glycerinum pepsini, Br.—*Glycerin of pepsin*, E.; *Glycéré de pepsine*, Fr.; *Pepsin-Glycerit*, G.

Preparation.—Take of pepsin, 800 grains; hydrochloric acid, 110 minims; glycerin, 12 fluidounces; distilled water, a sufficient quantity. Mix the hydrochloric acid, the glycerin, and 6 fluidounces of distilled water; then add the pepsin; after 1 week pour off the clear liquid, or filter; add sufficient distilled water to produce 1 pint (20 fluidounces).—Br.

The glycerite of pepsin of the National Formulary is very similar to the above preparation, but slightly stronger in digestive power. It is made as follows: Mix pepsin (U. S. P.) 85 Gm. with water 450 Cc. and hydrochloric acid 10 Cc., and agitate until solution has been effected. Then incorporate purified talcum 15 Gm. with the liquid, filter, returning the first portions of the filtrate until it runs through clear, and pass sufficient water through the filter to make the filtrate measure 500 Cc. To this add glycerin 500 Cc. and mix.

Both preparations contain 5 grains of pepsin in each fluidrachm, but the pepsin of the U. S. P. is 20 per cent. stronger than that of the British Pharmacopœia.

Pepsin solutions are filtered with some difficulty. Paper-pulp will be found preferable to purified talcum.

Action and Uses.—Glycerite of pepsin may be employed for the same purposes as PEPSINUM (which see). Because of the laxative properties of glycerin the administration of this remedy may be advantageous in cases of indigestion if constipation exists.

GLYCERITUM PHENOLIS, *U. S.*—Glycerite of Phenol.

Glyceritum acidi carbolici, U. S., 1890; *Glycerinum acidi carbolici*, Br.; *Glycerite of carbolic acid*, *Glycerin of phenol*, E.; *Glycéré d'acide phénique*, *Glycérine phéniquée*, Fr.; *Phenol- (Phenyl-) Glycerit*, G.

Preparation.—Liquefied phenol, 20 Gm.; glycerin, 80 Cc.; to make 100 Cc. Add the liquefied phenol to the glycerin and stir until thoroughly mixed.—U. S.

(5 fluidrachms of liquefied phenol may be mixed with 17 fluidrachms of glycerin.)

Take of phenol, 1 ounce; glycerin, sufficient to produce 5 fluidounces. Triturate the phenol with the glycerin until solution is effected.—Br.

Action and Uses.—Glycerite of carbolic acid forms a safe and agreeable method for the administration of PHENOL (which see) in that it renders the acid miscible in all proportions with water. The internal dose is from 5 to 10 minims (0.30–0.60 Cc.), well diluted.

GLYCERITUM PLUMBI SUBACETATIS.—Glycerite of Lead Subacetate.

Glycerinum plumbi subacetatis, Br.—*Glycerin of lead subacetate*, E.; *Glycéré de sousacétate de plomb*, Fr.; *Bleiglycerit*, G.

Preparation.—Take of lead acetate, 5 ounces; lead oxide, in powder, 3½ ounces; glycerin, 20 fluidounces; distilled water, 12 fluidounces. Mix together and boil for 15 minutes; then filter and evaporate at a temperature not exceeding 105.5° C. (222° F.) until the product weighs 32¾ ounces, and has a specific gravity of 1.48.—Br.

Action and Uses.—This preparation is employed for the same purposes as Goulard's Extract, and by some is considered a better remedy, as the glycerin present prevents the formation of dry crusts upon the skin.

GLYCERITUM TRAGACANTHÆ.—Glycerite of Tragacanth.

Glycerinum tragacanthæ, Br.—*Glycerin of tragacanth*, E.; *Glycéré de gomme adragante*, Fr.; *Traganth-Glycerit*, G.

Preparation.—Take of tragacanth, in powder, ½ ounce; glycerin, 1½ fluidounces; distilled water, ½ fluidounce. Mix the tragacanth with the glycerin in a mortar, add the water, and triturate until a homogeneous paste is produced.—Br.

Action and Uses.—Glycerite of tragacanth is only employed in medicine as an excipient in the preparation of pill-masses.

GLYCYRRHIZA, *U. S.*—Glycyrrhiza.

Glycyrrhizæ radix, Br.; *Radix liquiritiæ*, P. G.; *Liquorice- or Licorice-root*, E.; *Süssholz*, G.; *Réglisse, Bois de réglisse, Bois doux, Racine douce*, Fr.; *Orozuz Regaliz, Palo dulce*, Sp.; *Radice di Liquirizia* (or *Regalizia*), It.; *Raiz de Alcacuz*, Port.

The dried rhizome and root of *Glycyrrhiza glabra* L. (*G. officinalis* Lepech.; *Liquiritia o.* Moench; *G. vulgaris* Gueld), which yields the *Spanish*, *French*, or *Sicilian Liquorice*, or of *G. glandulifera* Wald. et Kitt. (*G. glabra glandulifera* Regel et Herder), yielding the *Russian Liquorice* (Fam. *Leguminosæ*).

Fig. 201.

Glycyrrhiza (Nat.): A, Russian, small root; B, Spanish, medium-sized root.

Licorice is official in all pharmacopœias, which differ as to the variety or varieties recognized, as to the botanical name employed, and as to the drug being peeled or unpeeled. The Br. P. requires that it be peeled. Several require that it be unpeeled, and one or two name *G. echinata* as the source.

Origin.—The licorice plants are shrubs, natives of southeastern Europe and southwestern Asia, as far as Persia, the *G. glabra* ranging more especially to the westward, the *G. glandulifera* more to the eastward. The plants are graceful, with light, spreading pinnate foliage, presenting an almost feathery appearance from a little distance, and bearing racemes of papilionaceous small, yellowish-white or purplish flowers, and a short pod somewhat resembling a partly grown pea-pod in form, glandular, hairy in the one species, smooth in the other. The

Fig. 202.

Spanish (rhizome).

Fig. 203.

Russian (root).

underground system, as in so many Leguminosæ, is double, the one part consisting of a vertical or tap-root, often with several branches, penetrating to a depth of 3 or 4 feet, the other

of horizontal rhizomes running near the surface of the ground. With the latter, horizontal roots, sometimes exist. Various indications point to the function of this plant of fixing atmospheric nitrogen, as do so many other members of the family. It prefers the rich, fine soil of bottom-lands in river valleys, where there is an abundance of moisture during the growing period, but where the ground bakes hard during the hot late summer months. Although this dry heat is very favorable for the formation of the sweet constituents, it renders collection difficult until after the early autumn rains, when the harvest commences.

Not only can the plant not endure severe freezing, but cool weather interferes with the formation of its useful juice and also renders it woody. It has been found that a climate particularly favorable to the production of the orange is favorable to that of licorice.

Owing to the depth to which the root penetrates and its ready propagation from detached pieces, the plant is a most persistent weed in cultivated grounds and exceedingly difficult of extirpation. It is very healthy and robust, and little subject to disease, at the same time successfully occupying the ground to the exclusion of other plants. For this reason the continuation of the natural supply may be considered as assured, though it is liable, of course, to suffer severe reduction from over-collection. The supply of natural root has suffered violent fluctuations, owing to the exhaustion of supplies in the districts previously worked, alternating with over-production from newly opened districts. This fact, coupled with the operations of speculators, has resulted in equally great fluctuations in quality, the new districts yielding full-grown root of good quality, the older ones that which has not been allowed to develop properly. The same ground yields a crop every 3 or 4 years. It may be said that the 4-year-old growth is the best. That of the third year and earlier is deficient in sweet substance, but immediately after the fourth year the texture begins to take on a tough, coarse, and woody character. It is desirable, furthermore, to collect the roots of those plants which have never borne fruit, since that process exhausts the sweet substance of the sap.

Cultivation.—Russian Licorice has been comparatively little cultivated, owing to the extensive areas of wild land which it occupies. Up to the year 1890, the cultivation of Spanish Licorice was small or moderate in comparison with the wild collection. Owing, however, to the depletion of the natural supplies of root of good quality, this cultivation has grown rapidly during the past decade in southern and south-central Europe, where the climate is favorable. Cultivation on a small scale, the roots mostly sold and consumed in their fresh and succulent state, has existed in England for a very long time.

The cultivation of licorice is easy, sure, and profitable, and, if properly conducted, conducive to the betterment of the soil, and it is an industry which might be pursued with great advantage in our Southern States.

Propagation is effected by means of cuttings, resulting as waste from the harvesting process. These are planted about 4 inches underneath the surface, in rows about 4 feet apart. During the first 2 years the growth is very slight, and the intervening space is utilized for the production of potatoes, cabbages, and similar crops. The soil being heavily fertilized for the production of licorice, these crops are usually very luxuriant. After the second year the growing licorice plants cover the entire soil to the exclusion of other growth. Harvesting occurs in the autumn of the fourth year. The soil is carefully removed from the space between the rows to a depth of 2 or 3 feet, as required, thus exposing the roots and rhizomes at the side, the whole being then removed bodily. The earth from the next space is then removed and thrown into the trench thus formed, and these operations repeated continuously. The roots are carefully stored in cellars and the trimmings are used for replanting.

Numerous commercial varieties, depending upon the different producing sections, are recognized by dealers, but their differentiation in description is almost impossible. Calabrian Licorice is generally preferred. By far the larger part of the Italian and Sicilian crop is now manufactured there and exported in the form of the extract. Spain formerly yielded most of the American supply, but that of first grade was long since depleted to the point of scarcity. The annual import of licorice root into the United States is probably not far from 100,000,000 pounds.

Description.—*Spanish Licorice.*—In long, cylindrical pieces, from 5 to 15 Mm. ($\frac{1}{5}$ to $\frac{3}{5}$ In.) thick, longitudinally wrinkled, externally grayish-brown to dark-brown, warty; internally tawny yellow; pliable, tough; fracture coarsely fibrous; bark rather thick; wood porous, but dense, in narrow wedges: medullary rays linear; taste sweet, very slightly acrid.

The underground stem, which is often present, has a similar appearance, but contains a thin pith.

Russian Licorice occurs in large, usually crooked pieces, often several feet in length and 5 Cm. (2 In.) in thickness, deprived of the outer bark, pale-yellow without, internally of a lighter yellow than the Spanish, and softer and of lower specific gravity, its cellular elements larger, its taste less sweet, and the wood frequently cleft. Any blackened, knotty, bitter portions should be removed before using.

The powder is identified by (1) the character and location of starch-grains and crystals; (2) the very numerous bast-fibers of peculiar appearance and the almost identical wood-fibers; (3) the peculiar sieve-tissue. The starch-grains are irregularly spheroidal, mostly solitary, and range from 1.5 or 2 to 20 mikrons in diameter. They are contained in medullary-ray and parenchyma-cells, and are often associated in the same cell with the monoclinic prismatic crystals of calcium oxalate, sometimes also with oil-globules. The bast- and wood-fibers are yellow, thick-walled, and doubly pointed. Part of the sieve-tubes have their cavities nearly or quite obliterated by cell-wall thickening. That of the Russian variety is of distinctly lighter color and less sweet, is wanting in cork-cells which are present in the other; its fibers are much less numerous and its parenchyma-cells are larger. Adulteration with the stem is indicated by the presence of pith-cells. The use of inferior grades is best indicated by color and taste, requiring experience. Most other adulterants are at once indicated by their different starch-grains.

Statements concerning the relative quality and taste of Spanish and Russian licorice are contradictory. This probably results partly from the comparison of a superior lot of one variety with an inferior lot of the other, partly from the method of preparation. The fact seems to be that the bitterness and acridity of licorice are practically confined to the bark. The bark being ground in with Spanish Licorice, a certain degree of this element must always be expected in it. The Russian Licorice, on the other hand, is freed from this defect through the removal of its bark, except as to its presence in the black knotty hollow spots, which should be carefully excised before grinding.

Constituents.—Licorice root contains 0.03 per cent. of volatile oil, 6 to 8 per cent. of glycyrrhizin, 2 to 4 per cent. of asparagin, 0.8 per cent. of fat, resin soluble in ether, sugar, gum, a trace of tannin, yellow coloring-matter, and *glycyrmarin*, a bitter principle occurring mostly in the bark. *Glycyrrhizin* (which see) is the acid ammonium salt of *glycyrrhizic acid* ($C_{44}H_{62}NO_{18}NH_4$). This acid is a brown gelatinous mass with a bittersweet taste, soluble in hot water, with which it swells to form a yellowish transparent jelly, slightly soluble in absolute alcohol, more so in 90 per cent. alcohol, and insoluble in ether. On boiling with dilute acids it splits into *para-saccharic acid* ($C_6H_{10}O_8$), which reduces Fehling's Solution, and *glycyrrhetin* ($C_{32}H_{47}NO_4$), which is a white, tasteless powder soluble in alcohol, and insoluble in water, ether, or alkalies.

Pharmaceutical Preparations.—Aromatic Elixir of Glycyrrhiza, Elixir of Glycyrrhiza, N. F.; Compound Powder of Glycyrrhiza, Fluidextract of Glycyrrhiza, Pure Extract of Glycyrrhiza, U. S. P.; Solution of Extract of Glycyrrhiza, Syrup of Glycyrrhiza, N. F.

Action and Uses.—Licorice is an excellent demulcent and slight laxative; and an infusion, made by boiling 1 ounce (30 Gm.) of the bruised root deprived of its cortical layer with 1 pint (480 Cc.) of water for a few minutes, may be employed in the treatment of sore throat and in catarrhal conditions of the genito-urinary and intestinal tracts. Licorice is also employed for the purpose of disguising the taste of acrid or bitter drugs, such as mezereon or quinine. In the form of the compound licorice powder it is employed as a laxative, the properties of which, however, are mainly due to the senna.

Other Species and Allied Products.—The genus *Glycyrrhiza*, L., contains about 12 species, 10 of them in the section of licorice, and all of these having roots more or less sweet, but most of them not sufficiently so to be of use. There are contradictory statements concerning the quality of *G. echinata* L., due perhaps to its having been confused with *G. glandulifera*. Statements are made that some superior Italian root is yielded by that species, but Flückiger states that it is worthless. The latter statement is probably the correct one. *G. lepidota* Pursh (*American Licorice*) is a species of the northwestern United States, and has there been somewhat used. The rhizome is said to resemble that of Spanish Licorice, though it is smaller. It yields 6.39 per cent. of glycyrrhizin, which, however, when ammoniated, leaves a somewhat bitter after-taste. The leaves and root of *Abrus precatorius* (see Abrus) contain glycyrrhizin, and the latter is used in India as a substitute for licorice root.

GLYCYRRHIZINUM AMMONIATUM, *U. S.*—Ammoniated Glycyrrhizin.

Glycyrrhizinum ammoniacale, Glycyrrhizine ammoniacale, Fr.; *Ammoniak-Glycyrrhizin*, G.

Preparation.—Glycyrrhiza, in No. 20 powder, 500 Gm.; water, ammonia water, sulphuric acid, of each a sufficient quantity. Mix 475 Cc. of water with 25 Cc. of ammonia water, and, having moistened the powder with the mixture, macerate for 24 hours. Then pack it moderately in a conical glass percolator, and gradually pour water upon it until 500 Cc. of percolate are obtained. Add sulphuric acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer, wash it with cold water until the washings no longer have an acid reaction, redissolve it in water with the aid of ammonia water, filter if necessary, and again add sulphuric acid so long as a precipitate is produced. Collect this, wash it, dissolve it in sufficient ammonia water previously diluted with an equal volume of water, and spread the clear solution upon plates of glass, so that when dry the product may be obtained in scales.—U. S.

This is Roussin's process, as modified by Appenzeller (1876), who noticed that a considerably larger quantity, somewhat darker in color, is obtained by exhausting the root with diluted ammonia water, and that the scales have a more pleasant taste if licorice root deprived of the brown corky layer be used. Commercial extract of licorice yields a still darker and less pleasant product. The cold percolate, if not too strongly alkaline, when heated to boiling deposits most of the albumen; this and other impurities are removed by again dissolving the precipitated glycyrrhizic acid in ammonia and reprecipitating it by an acid before its ammoniacal solution is finally evaporated and scaled. The yield is about 10 per cent.

Properties.—Ammoniated glycyrrhizin is in transparent dark-brown or brownish-red scales, inodorous, of a very sweet taste, and readily soluble in water and in diluted alcohol. The aqueous solution, when heated with potassium or sodium hydroxide, evolves vapor of ammonia. On supersaturating the aqueous solution with an acid, a substance (glycyrrhizin) is precipitated which, when dissolved in hot water, forms a jelly on cooling. This substance, when washed with diluted alcohol and dried, appears as an amorphous yellow powder of a strong, bitter-sweet taste and an acid reaction. On ignition glycyrrhizin should leave not more than a trace of ash.—U. S. The scales consist mainly of ammonium glycyrrhizate, $(NH_4)C_{44}H_{62}NO_{18}$ (Habermann), with a variable quantity of glycyramarin. They are insoluble in ether, sparingly soluble in strong alcohol, become darker colored at 100° C. (212° F.), and at a higher heat melt, being decomposed at the same time. Glycyrrhizic acid is tribasic; the taste of its alkali salts is very sweet, and in the pure state free from the characteristic after-taste of licorice; their solutions in water foam strongly on agitation and produce voluminous precipitates with most salts of the heavy metals.

Action and Uses.—Ammoniated glycyrrhizin may be used as a substitute for other preparations of licorice. It should not be prescribed in either strongly acid or alkaline mixtures. The dose is from 5 to 15 grains (0.30–1 Gm.).

GNETACEÆ.

A small family of 3 genera and about 40 species, of great interest to botanists, since it connects the Gymnosperms with the Angiosperms. Its medicinal relations have not been developed, though powerful alkaloids, as well as much tannin, exist in its members. Several species of *Gnetum*, L., yield edible fruits and gums. The physiologically active substances pertain chiefly to the genus *Ephedra*, L., which comprises some 25 species, mostly in the north-temperate zone, a few extending into the elevated and temperate regions of South America. The important medicinal species is *E. antisyphilitica* C. A. Meyer, the *Mountain rush*, *Joint fir*, *Shrubby horsetail*, *Teamster's tea*, *Mormon tea*, *Brigham weed*, *Canutillo*, *Tepopote*, of the desert regions of the southwestern United States and Mexico. The plant is a low, diœcious, practically leafless shrub, 2 or 3 feet high. The erect, opposite, rather slender branches are densely fascicled, after the manner of broom-tops, terete but ribbed and channelled, and mostly terminating in hard and sharp points. They are of a yellowish-green color, and, at least the younger parts, minutely resinous. The leaves are reduced to whitish scarious sheaths, mostly 2-cleft, varying greatly in length, from short-triangular to linear-subulate and persisting for years. The staminate aments are about a fourth of an inch long, their bracts opposite and imbricated, and their flowers consisting of about 8 monadelphous stamens, the anthers nearly sessile upon the stamen-column. The fertile aments are solitary,

nearly sessile, bracted with 4 pairs of thick, broadly ovate scales, those of each pair connate at the base. Each produces 1 or 2 smooth, oblong-ovate, and triangulate fruits. The plant has an astringent and bitter taste. Several other species closely resemble and are frequently used for it. The only known constituent upon which its activity can be supposed to depend is a glucosidal tannin, yielding a reddish powder which Loew has named *ephedrin*. Ephedra has been recommended as a remedy in the treatment of gonorrhœa, but has never met with general favor by the profession. A fluid extract may be given in doses of 1 or 2 fluidrachms (4–8 Cc.).

E. vulgaris Rich. is a Japanese species, containing the powerful alkaloid *ephedrine* ($C_{10}H_{15}NO$), which paralyzes the heart and respiration. Locally applied, it is a fairly good mydriatic, dilatation occurring, without effect upon accommodation, in about an hour and lasting about as long as that produced by atropine. *E. monostachya* L. (*E. monosperma* Gmel.; *E. polygonoides* Pall.) is a widely distributed species of Europe and Asia, largely employed by the peasantry as an antisyphilitic, diaphoretic, and antirheumatic. Grache, who has seen it so used in Poland, states that it is very inferior to the salicylates in rheumatism. It bears various local names, such as *Dschorisdsna*, *Katyr koiruch*, *Tschergak*, etc. Its alkaloid has been called *pseudo-ephedrine* ($C_{13}H_{19}NO$), though this name has been applied to a secondary alkaloid of *E. vulgaris*, from which this is said to be distinct. It melts at 112° C. (233.6° F.), is soluble in water and alcohol, in 11 parts of chloroform and 100 of ether, and yields benzoic acid when oxidized by potassium permanganate. It is at first tasteless, afterward producing a burning and benumbing effect. It is not mydriatic.

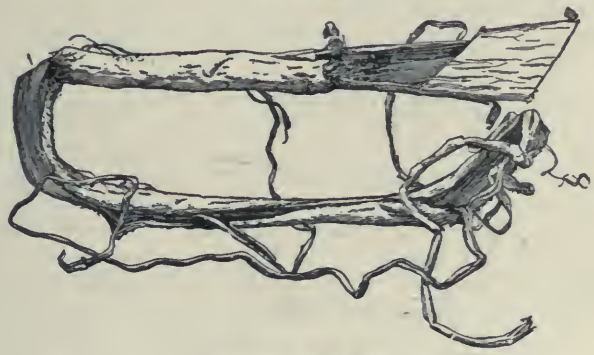
GOSSYPII CORTEX, *U. S.*—Cottonroot Bark.

Baumwoll-Wurzelrinde, G.; *Ecorce de la racine de cottonnier*, Fr.; *Corteza de la raiz d'algodon*, Sp.

The dried bark of the root of *Gossypium herbaceum* L., or of other cultivated species of *Gossypium* (Fam. *Malvaceæ*).

Origin.—(For an account of the cotton plant, see GOSSYPIUM PURIFICATUM.) Information concerning the comparative composition and properties of the barks of the

FIG. 204.



Cottonroot bark (Nat.).

different species is greatly needed; also concerning those of the barks collected at different seasons and under different conditions. Our ideas of its use appear to have been derived from the negroes of our Southern States, who doubtless brought the knowledge with them from Africa, so that it is likely that the species occurring there is that originally so used. It seems highly probable that the bark from perennial tropical plants would show a superiority over that growing as an annual farther north. It is not unlikely, moreover, that the destruction of this plant by frost, even though the latter does not reach the root, may affect the composition and properties of the drug.

Description.—In elongated, thin, flexible bands or quilled pieces, somewhat fuzzy from partly detached bast-fibers and with a few coarse rootlets adhering; outer surface yellow to yellowish brown, with slight longitudinal ridges or meshes, small black circular dots or transverse lines, and dull, brownish-orange patches from the abrasion of the thin cork, or the entire corky layer wanting; inner surface whitish, slightly silky-lustrous and finely long-striate; bast-fibers long, tough, and the bast-layer separable into thin laminæ; inodorous and of a slightly resinous, pungent and acrid, and faintly astringent taste.

The powder shows large and thin-walled, very irregular parenchymatic cells, containing abundant starch-grains, mostly solitary and spheroidal, 5 to 10 mikrons broad, many with solitary rosettes of calcium oxalate from two to three times as large as the starch-grains, occasionally accompanied by solitary prismatic crystals, numerous large resin-cells, and very numerous, very long, slender, flexible, yellowish bast-fibers with only moderately thick walls.

The bark of the stem, which has been offered to us as a substitute, is paler, usually greenish or grayish, thinner, and whitish internally.

Constituents.—Cottonroot bark yields starch, glucose, gum, fixed oil, a little tannin, and 8 per cent. of a peculiar acid resin which is colorless and soluble in water, but on exposure absorbs oxygen and becomes red and insoluble. It is also soluble in 14 parts of alcohol, 15 of chloroform, 23 of ether, 122 of benzene, and in alkalies, and is deposited by the fluid extract on standing. The aqueous solution of the alcoholic extract is stated to contain a principle which gives a purplish-black precipitate with ferric chloride.

Action and Uses.—Cottonroot bark has long been employed by the negroes of the South as an abortifacient. It has been recommended as an excellent emmenagogue, and is said to be especially useful in the treatment of subinvolution and in suppression of the menses resulting from exposure to cold. It may be employed as an oxytocic during labor, and is said to be a much safer remedy than ergot, as it does not cause tetanic contractions of the uterus to so marked a degree. In the control of hemorrhage cottonroot bark is inferior to ergot, but is said to be more efficacious than the latter remedy in the treatment of uterine fibroids. The fresh is probably more reliable than the dried bark, but if gathered late in the autumn before frost and properly dried, it still possesses some of its medicinal properties.

The dose of the fluidextract is from ½ to 1 fluidrachm (2–4 Cc.). A decoction (4 ounces to 1 pint) may be administered in doses of 2 fluidounces (60 Cc.) every half hour, as an oxytocic.

Allied Products.—The flowers of the cotton plant contain the glucoside *gossypetin* ($C_{16}H_{12}O_8$), soluble in alkalies with an orange-red color, becoming green on oxidation. It contains no methoxyl groups, and on fusion with alkali yields phloroglucinol and protocatechuic acid. It is similar to thujetin.

GOSSYPIUM PURIFICATUM, *U. S.*—Purified Cotton.

Gossypium, Br.; *G. depuratum*, P. G.; *Bombyx, Lana* (*Lanugo s. Pili*) *gossypii.*—*Absorbent cotton*, E.; *Gereinigte Baumwolle*, G.; *Cotton absorbant, C. Hydrophile*, Fr.; *Algodon*, Sp.; *Cotone Absorbente, C. Idrofilo*, It.

The hairs of the seed of *Gossypium herbaceum* L. and of other species of Gossypium, freed from adhering impurities and deprived of fatty matter.

Origin.—The cotton plants are herbs, shrubs, or small trees with 3- to 5-lobed leaves and showy axillary flowers, having a 3-leaved involucre, a cup-shaped calyx, 5 petals, numerous stamens, and producing a 3- to 5-celled capsule, the "cotton-boll," which opens by as many valves; the numerous seeds are densely covered with long woolly hairs. It is these hairs which constitute cotton.

Fig. 205.

Cotton fibers.

The genus comprises from 9 to 12 species, the number uncertain because of the numerous forms of cultivation, which may be species, hybrids, or merely cultivation-varieties. The best authorities reduce the forms of cultivation to the origin of the following species: *G. Barbadense* L. (*G. vitifolium* Lam.; *G. Peruvianum* Cav.; *G. punctatum* Schum. et Thou.; *G. acuminatum* Roxb.; *G. religiosum* Parlatore), the *Sea Island* or *Long-staple cotton*, having all the seed-hairs long and the leaf-lobes lanceolate or lance-oblong; *G. herbaceum* L., the *Upland, Common*, or *Short-staple cotton;* and *G. arboreum* L. (*G. sanguineum* Hook.), the *Tree-cotton*, the two last having short, thick hairs intermixed with the long ones upon the seed, *G. herbaceum* with ovate, *G. arboreum* with narrowly lanceolate leaf-lobes. *G. Barbadense* is regarded as a native of the New World, the others of Asia and Africa. *G. religiosum* L. is very likely distinct. Its hairs are yellow and yield the *Nanking* or

Egyptian cotton. Besides these, 6 uncultivated species are known in the Old World. Cultivation occurs in all tropical countries where there is sufficient rain and in all warm-temperate countries where the season is sufficiently long for the maturity of the seeds. Any of these products may be utilized for absorbent cotton, though the longer the staple, the better the properties for medicinal purposes. In its natural condition cotton is so thoroughly impregnated with fat that it is not fit for use as an absorbent, and the removal of this fat is a work of some difficulty. Hence the occurrence in the market of much so-called absorbent cotton which has been very imperfectly, or even slightly purified, and the necessity of careful examination.

Preparation.—Official purified cotton, commercially known as "absorbent cotton," is prepared by first boiling carefully carded cotton in a weak alkaline solution, for the purpose of removing fatty matter, after which it is rinsed in water and immersed in a weak solution of chlorinated lime. It is subsequently washed in water slightly acidulated with hydrochloric acid, and again well rinsed in water. If the cotton still retains fat, the treatment with alkali is repeated until the final product is found completely absorbent. For the more thorough removal of water after washing the cotton recourse is had to centrifugal machines, by means of which the material is rapidly dried.

Description.—Consisting of soft, narrow-filiform, thin-walled, simple cells, which are about 12 to 38 Mm. (½ to 1½ In.) long, and appear under the microscope as flattened hollow and twisted bands, which are slightly thickened at the edges, finely and spirally striate, and nearly cylindrical at the apex; odorless and tasteless, insoluble in ordinary solvents, but soluble in ammoniacal solution of oxide of copper, and is colored blue by solution of zinc chloride and iodine, but not by solution of iodine. It consists of nearly pure cellulose, and yields with nitric acid an explosive nitro-compound (see PYROXYLIN), which is used in preparing collodion.

Cotton should be perfectly free from all visible impurities, and, on combustion, should not leave more than 0.8 per cent. of ash.

When purified cotton, previously compressed in the hand, is thrown on the surface of cold water, it should readily absorb the latter and sink, and the water should not acquire either an acid or an alkaline reaction (evidence of proper purification).

Pharmaceutical Preparations.—PYROXYLIN, U. S. P.; STYPTIC COTTON, N. F.

Uses.—Absorbent cotton is largely employed as a dressing in the treatment of superficial abrasions, burns, blisters, and erysipelas. It may also be used to protect inflamed joints in rheumatic fever. In surgery it is largely employed for padding splints, and when sterilized is employed as a substitute for sponges and largely as a dressing for wounds. Cotton tampons have also been used for the purpose of correcting uterine displacement, but carded wool forms a more satisfactory material.

Allied Substances.—Innumerable fibers have been used for textile purposes, but none has been found exactly to replace cotton. A number of so-called "Tree-cottons" are known in the tropics, mostly related to cotton (*Ochroma*, *Bombax*, *Eriodendron*, etc.), and bear more or less of a resemblance to it. It has been proposed to use the fiber of *Boehmeria nivea* Gaud., the Asiatic *Ramie*, as a substitute, but the suggestion has not been favorably received.

GRAMINEÆ.—The Grass Family.

This vast family, of more than 300 genera and not less than 4000 species, is probably the most important in the vegetable kingdom, from an economic standpoint. In their proper alphabetical sequence are treated TRITICUM, ZEA, AMYLUM (many starches being derived from this family), SACCHARUM, ALCOHOL and other alcoholic liquids, MALTUM, DIASTASE, HORDEUM, and FARINÆ AVENÆ and TRITICI. Besides the minor drugs discussed below and the numerous highly important cereal grains, a number of important volatile oils are yielded by the genus ANDROPOGON (see OLEUM CITRONELLÆ); numerous fibers are obtained from the bamboos and other grasses; the Bamboos themselves contribute most important building- and utensil-materials, as well as boats, weapons, etc., in tropical regions; great quantities of paper are made from straw and other grass-fibers, and our most important forage-plants pertain to this family.

Medicinal Grasses of Minor Importance.—A great many members of this family are

used locally, in nearly all countries, as diuretics. Cumarin is contained in various species of *Savastana*, Schrank (*Hierochloa* Gmel.), as well as in *Anthoxanthum* L., both of which are variously known as *Sweet-scented grass*, *Holy grass* (because scattered in front of churches and religious processions), *Vanilla grass*, etc. In Brazil, *Elionurus candidus* Hack. is used locally and internally in catarrhal complaints, *E. rostratus* Nees as an aphrodisiac and general stimulant. Several species of *Andropogon* are more or less bitter, and are used as simple bitters, diuretics, and tonics. *Melinis minutiflora* Beauv. contains a peppery-tasting resin, and is used as an intestinal astringent and stimulant.

Poisonous Grasses.—Poisonous products, in the proper sense, are almost unknown in the Grass family, though many species of *Stipa*, L., as well as *Hordeum jubatum* L., *Heteropogon contortus* R. et Sch. (*Spear grass*, etc.), and other grasses, produce long, stiff awns which are mechanically fatal to sheep and other animals by piercing the abdominal organs.

Lolium, *Darnel* or *Bearded darnel*, *Cheat*, *Ivary*, *Bragge* or *Dragge*, *Drake*, *Drank*, *Drunk*, *Droke*, or *Dravic neele*, or *Lover's steps* (E.), *Lolch* or *Taumelkorn* (G.), *Ivraie* (Fr.), the seed of *Lolium temulentum* L. (*L. arvense* Withering), is a notable exception, being distinctly narcotic or delirifacient. The plant is a native of temperate regions of Europe and Asia, and is sparingly naturalized in the United States. It infests grain-fields, and has thus been responsible for numerous cases of poisoning, through its presence in flour. In some of the reports of such cases, Cockle has probably been mistaken for this seed, but many others are authenticated. The plant is annual, growing nearly as high as the grain, the leaves 10 to 25 Cm. (4 to 10 In.) long, 2 to 6 Mm. ($\frac{1}{12}$ to $\frac{1}{4}$ In.) wide, rough on the upper surface, smooth underneath, the spikes about 10 to 30 Cm. (4 to 12 In.) long, bearing single spikelets alternating in notches of the rachis, with the back of the scale toward the latter. The spikelets are 4- to 8-flowered, the lowermost scale empty in each of the lateral spikelets, the lower two empty in the terminal. The palets bear a double keel. The grain is oblong-ovoid, nearly 6 Mm. ($\frac{1}{4}$ In.) long, enclosed in the palets, grooved on the inner face, pale-brown, internally white, odorless and of a farinaceous, afterward bitterish taste. The starch-grains are reported as being about one-third as large as those of wheat starch and circular, with a moderately white margin and a bright, strongly translucent surface without markings. Besides the ordinary constituents of the cereals, Antze, in 1891, reported this seed as containing the volatile alkaloid *loliine*, forming crystalline salts, and crystalline *temulentic acid*, which melts at 234° C. (453.2° F.). Hofmeister subsequently stated that he was unable to verify this statement, but reported the alkaloid *temuline* ($C_7H_{12}N_2O$), which acts as a nerve poison. He did not believe that the intestinal action of Darnel could be due to this base, but regarded it as probably due to the fat-acid which was freed during digestion. The *Natyuna* of Paraguay may be the same or a related species of Lolium. The drug is a powerful irritant, depressant, and narcotic poison, causing severe gastro-enteritis, vomiting, purging, dyspnœa, headache, vertigo, muscular tremors, and profound sleep. The drug is said to have been employed as an adulterant to malt, and it is stated that the liquor brewed from this produces a peculiar intoxication. Lolium is rarely employed in medicine, but may be locally applied as an ingredient in poultices for the relief of rheumatic and neuralgic conditions.

The seeds of *Paspalum scrobiculatum* L. (*P. Commersonii* Lam.), the *Koda*, *Kodrava*, *Aruga*, etc., of the East Indies, is reputed similarly poisonous.

The great importance of cereals as foods renders the following table (from Stewart's *Feeding Animals*) of their composition interesting and important (for wheat, see FARINA TRITICI; for oats, FARINA AVENÆ; for barley, HORDEUM):

	Total nutrients.				Digestible nutrients.		
	Albuminoids.	Carbohydrates.	Fat.	Ash.	Albuminoids.	Carbohydrates.	Fat.
Rye	11	69.2	2	2	9.9	65.4	1.6
Rye bran	14.5	53.5	3.5	4.5	12.2	46.2	3.6
Indian corn	10	68.0	7	2.1	8.4	60.6	4.8
Millet	14.5	62.1	3	3	9.5	45	2.6
Wheat middlings	13.9	63.5	3.3	3	10.8	54	2.9
Rice	7.7	75.2	0.4		6.9	72.7	0.3
Buckwheat	9	58.7	1.5		6.8	47	1.2
Buckwheat bran	17.1	46.4	4.4	.	13.5	44	3.9

In the feeding of armies and other large bodies of men, as well as of animals, and in stock-raising, the *nutritive ratio* and the *feeding-value* of foods and fodders are carefully esti-

mated and tabulated for purposes of comparison and reference. Making due allowance for digestibility and other conditions affecting health, feeders are enabled by these tables to select that food or fodder which, in the then state of the market, affords the desired nutrient combination at the lowest price. These tables are based upon the well-known fact that the hydrocarbons, carbohydrates, and albuminoid constituents bear pretty definite ratios to one another as to their nutrient value, the following figures being generally accepted. Assuming that the carbohydrates and the fats act in the same general way in nourishing the system, but that the latter are 2.4 times as efficient as the former, the sum of the values of these two is obtained by multiplying the amount of fat by 2.4 and adding the product to the carbohydrates. This sum is then divided by the amount of albuminoids present. It is apparent that the quotient thus obtained will represent the number of carbonaceous units for each albuminoid unit present in the food. Thus, taking the composition of corn, its digestible fat amounts to 4.8, which multiplied by 2.4 gives us 11.52. Adding this to 60.6 carbohydrates we get 72.12 as the total number of carbonaceous units; dividing this by 8.4, the percentage of albuminoids, we get about 8.58, and we say that the nutritive ratio of corn is 1 to 8.58, or, as commonly written, 1 : 8.58, or, it is frequently expressed by saying that the nutritive ratio is 8.58.

The feeding-value is obtained by a somewhat similar process. Assuming the market value of the digestible albuminoids in a given food as being 4½ cents per pound (Wolff's German tables) and the digestible fat the same, the digestible carbohydrates are reckoned at 0.9 cent per pound. These figures would make the feeding-value of corn : 4.8 lbs. of fat by 4½ cents, 21.6 cents; 60.6 lbs. carbohydrates by 0.9 cent, 54.54 cents; 8.4 lbs. albuminoids, 37.8 cents: or a total value of about $1.14 per hundredweight. Figuring out in the same way the value of any other food, we get its relative feeding-value as compared with corn. Any change in the market price of corn may then be applied *pro rata* to the other, and their relative cheapness or dearness in any state of the market almost instantly computed.

Besides the better known grains, there are many grasses whose seeds are used locally, by aborigines, for food purposes, as is the wild rice of our northwestern territory. It is altogether probable that if such a thing were possible as that all our cultivated grains of the present day might be lost to us, we should be able pretty well to replace them by improving, through cultivation, species not now used, or the uses of which are not generally known.

Cyperaceæ, the Sedge Family.—This family, of some 60 or 70 genera and about 2500 species, though closely related to the grasses, is of comparatively slight economic importance. The plants are distinguished from the true grasses by their solid stems, leaf-sheaths which are not connate around the stems, and the presence of but a single scale subtending each flower. They are mostly coarse, harsh, and indigestible, thus not adapted for food-purposes. The rhizomes of several are utilized as starchy foods. Quite a number possess volatile oils and aromatic properties, while others are rich in tannin and are used as astringents. Among the latter may be named *Scirpus lacustris* L., *S. dubius* Roxb. (*Allikee*), *S. grossus* L., the *Kasiru* or *Kachara* of India; *S. capsularis* Lour., the *Tang-sin-ts'au; Eriophorum latifolium* Hoppe (*Herba linagrostis*) and *Eleocharis tuberosa* Schult., the *Wu-yu, Puh-tsi*, or *Ma-tih-fen* of China. Among the more important aromatics and carminatives are *Cyperus sanguineo-fuscus* Nees, the *Cure-pire* of Paraguay; *C. elegans* Rottb., of Mexico; *C. pertenuis* Roxb., the Indian *Nagar-motha* or *Koriak; C. tegetum* Roxb.; *Kyllingia monocephala* Rottb. (used in Paraguay as a substitute for Calamus); *K. aphylla* Kunth; *Mariscus patulus* Schrad.; and *Carex arenaria* L., the rhizome of which is used as a substitute for Sarsaparilla. *Scirpus capillaris* is used in Spanish America under the name *Espartillo*, as a pectoral. *Adrue* or *Guinea rush* is the rhizome of *Cyperus articulatus* L., which, besides being used as a carminative, has a high repute in the East Indies for anti-emetic properties.

GRANATUM, *U. S.*—Pomegranate.

Granati cortex, Br.; *Cortex granati*, P. A., P. G.—*Bark of pomegranate*, E.; *Granatrinde*, G.; *Grenadier*, Fr. Cod.; *Ecorce de balaustier* or *de Grenadier*, Fr.; *Corteza de granado*, Sp.; *Corteccio de Melogranato, or Melograno*, It.; *Casca de Romeira or de Romanzeira*, Port.

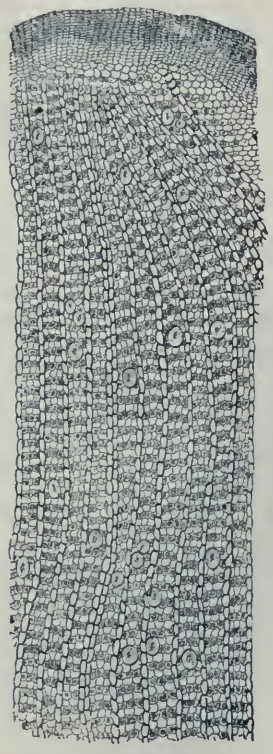
The dried bark of the stem and root of *Punica Granatum* L. (*Granatum Punicum* St. Leg.—Fam. *Punicaceæ*).

Granatum is official in most pharmacopœias, which differ as to the use of the root-bark or stem-bark, or both. The Swiss requires that it be used within a year after collection. Some require that it be collected from uncultivated plants.

Origin.—The pomegranate is indigenous to southwestern Asia from northern India to Palestine. It has been cultivated from remote antiquity, and is now met with in all subtropical countries. It is a very handsome shrub or small tree about 6 Mm. (20 Ft.) high, with lanceolate or oblong, pointed, entire and shining leaves, lovely

crimson, or rarely whitish flowers, and producing a depressed globose fruit of the size of an orange, irregularly divided by a transverse dissepiment into two unequal parts, the lower and smaller of which is about 3-celled and the upper 5- to 9-celled. The numerous seeds are oblong, irregularly angular from pressure, each invested with a fleshy pink-colored translucent coating. This pulp and the abundantly exuding juice are acid, sweet, and very refreshing in the ripe fruit, astringent and disagreeable in the unripe. There is conclusive evidence that the root-bark is several times richer in alkaloid than the stem-bark, and that deterioration is rapid when the bark is kept. There is also some evidence indicating that the bark of the white-flowered variety is richer.

Fig. 206.



Punica Granatum: root-bark, transverse section (× 40).

Description.—In quills several inches in length, and 0.5 to 2 Cm. ($\frac{1}{5}$ to $\frac{4}{5}$ In.) in diameter, or in broken pieces of the same, the bark 1 to 3 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ In.) thick; outer surface consisting of broad, shallow, rough, commonly short and reticulated, yellow fissures, alternating with less roughened, gray or slightly purplish-gray bands having sharp, lightly elevated margins, and usually more or less marked with small blackish spots of lichen; root-bark, especially the thicker pieces, browner, less fissured, more or less scaly-roughened and marked with conchoidal depressions; inner surface finely striate, with some longitudinally elongated, blister-like elevations, and varying in color from pale-greenish-yellow to cinnamon brown; fracture short, granular, greenish yellow, and showing a somewhat laminated structure; taste astringent, very slightly bitter.

Granatum is said to be adulterated with box-wood bark and barberry bark, but it is impossible to mistake either for it, as they are very bitter. The appearance of barberry bark bears not the slightest resemblance to it, and that of box-wood is nearly white on the inner surface.

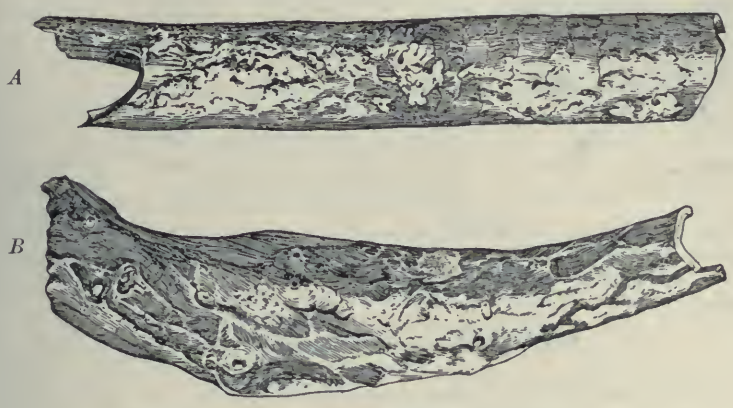
The powder is of a gray brown, usually with a greenish tint if of the stem-bark. Its characteristic element under the microscope is its rosettes of calcium oxalate, contained in regular rows of square cells, alternating with rows of empty cells. There is an abundance of starch, the grains either simple or compound, the larger reaching a diameter of 15 to 20 mikrons. Stone-cells occur sparingly.

Constituents.—The bark contains from 20 to 22 per cent. of tannin, gallic acid, mannit (formerly called punicin or granatin), yellow coloring-matter, and from about 1 to 3 per cent. of four alkaloids which probably exist as tannates in the drug. It yields from 10 to 17 per cent. of ash. The tannin is a mixture of gallotannic acid and *punicotannic* or *granatotannic acid* ($C_{20}H_{16}O_{13}$), which latter is insoluble in alcohol or ether, reduces silver and alkaline copper solutions, precipitates gelatin, tartar emetic, and iron salts, the latter black, and when boiled with dilute acids splits into sugar and *ellagic acid* ($C_{14}H_8O_9$). *Pelletierine* (*punicine*, $C_8H_{15}NO$) is a colorless, volatile liquid alkaloid, having the specific gravity 0.988 and boiling at 195° C. (383° F.), which dissolves in 20 parts of water and is miscible in all proportions with alcohol, ether, and chloroform, and rapidly resinifies by absorption of oxygen. It is dextrorotatory and forms crystalline salts.

Isopelletierine has the same composition and properties as pelletierine, but it is optically inactive, and its sulphate is deliquescent. *Methyl-pelletierine* ($C_9H_{17}NO$) is a volatile liquid alkaloid with very hygroscopic salts, and soluble in 25 parts of water, and in alcohol, ether, and chloroform. *Pseudopelletierine* (*granatonine*, $C_9H_{15}NO.2HO_2$) crystallizes in slightly volatile odorous prisms, which are optically inactive and soluble in water, alcohol, chloroform, and 9 parts of ether. Pelletierine predominates in the stem-bark, and methyl-pelletierine in the root-bark (Flückiger, 1891). The fresh drug is the more potent, for, as the bark becomes older, the alkaloids first become soluble with difficulty, then undergo decomposition. De Vrij, however, found bark active after keeping 11 years. Stoeder (1890), who examined the fresh bark in Java, obtained 3.75 per

cent. of alkaloidal hydrochloride from the white-flowered variety, 2.43 per cent. from the red-flowered, and 1.71 per cent. from the black-flowered. In 1894 he obtained

Fig. 207.



Granatum (Nat.): *A*, stem-bark; *B*, root-bark.

1.29 to 1.86 per cent. from Java root-bark, the greatest amount being from the white-flowered plant.

Valuation of Pomegranate Bark.—Inasmuch as the medicinal virtues of pomegranate bark reside wholly in the alkaloids present, which at times undergo decomposition with age, it is desirable to determine the value of the drug by assay, as follows: 20 Gm. of the coarsely powdered bark are put into a flask together with a mixture of 20 Cc. of chloroform, 80 Cc. of ether, and 20 Cc. of 10 per cent. ammonia-water, tightly corked, and allowed to macerate for 6 or 8 hours with frequent and active agitation. Decant exactly 50 Cc. of the ethereal liquid, representing 10 Gm. of the bark, and having passed the same through a small pledget of cotton if necessary, evaporate in a beaker to about 20 Cc., add 10 Cc. of tenth-normal sulphuric acid, mix well, and evaporate the remainder of the ether-chloroform mixture. The residuary aqueous fluid is passed through a small paper filter, the beaker and filter being washed with two successive portions of 3 Cc. each of water. After addition of a few drops of tincture of cochineal as indicator, the excess of acid is titrated with tenth-normal alkali solution, when the number of Cc. of acid found to have been neutralized by the alkaloids, multiplied by 0.01475 and then by 10, will express the percentage of total alkaloids in the drug. The factor 0.01475 represents the average of the equivalent of the 4 alkaloids. Good pomegranate bark should contain not less than 1 per cent. of total alkaloids when assayed by the above method.

Pharmaceutical Preparations.—Decoction of Pomegranate Bark, Br.; Fluid-extract of Granatum (Pomegranate Bark), U. S. P.

Action and Uses.—Because of its astringent properties a decoction prepared from the rind of the fruit of pomegranate was formerly used in treating relaxed conditions of the mucous membrane of the throat, in serous diarrhœas, and colliquative sweats. If given in large quantities, it may cause visual disturbances, excessive vomiting and purging, and weakness of the lower extremities, which may be followed by paralysis. The bark of the root is a very efficient tænifuge, and is said to be more active when fresh. A decoction prepared by macerating 2 ounces (60 Gm.) of the bark in 2 pints (960 Cc.) of water for 24 hours, and then slowly boiling to 1 pint (480 Cc.), may be given in doses of 1 ounce (30 Cc.) at intervals of 1 hour until all taken. The patient should not be fed for 12 hours prior to the administration of the drug, and if the purging does not occur shortly after its ingestion, castor oil or magnesium sulphate should be given. The active principle, pelletierine, is most efficient when administered in the form of the tannate in doses of from 3 to 5 grains (0.2–0.30 Gm.). Pelletierine is usually employed in the form of the sulphate or tannate, put up in syrupy solution. The sulphate is prepared by Parke, Davis & Co., and the latter by Tanret, a French manufacturer. The dose of these preparations is the contents of one bottle.

Allied Drugs.—*Granati Fructus Cortex; Cortex grenatorum* (*s. malicorii*), *Pericarpium granati.*—*Pomegranate-rind*, E.; *Granatenschalen*, G.; *Cuir de Pomme de grenadier*, Fr.—*Pomegranate-rind* forms irregularly curved fragments, which are about 2 Mm. ($\frac{1}{12}$ In. thick), externally somewhat finely tubercular and rough, of a brownish color with a yellowish or reddish tint, internally of a lighter color, marked with meshes indicating the depressions caused by the seeds. Some of the pieces are crowned by the thick tubular, 6- to 9-toothed persistent calyx, often enclosing the remains of the style and numerous stamens. They break with a short granular fracture, are nearly devoid of odor, and possess a strongly astringent taste. Examined by Reuss, pomegranate-rind was found to contain about 25 per cent. of tannin, 21 per cent. of extractive, and 34 per cent. of gummy matter. Bowman (1869) obtained 23.8 per cent. of tannin, which gives with ferric salts a blue-black precipitate. Flückiger obtained 5.9 per cent. of ash, calculated for the rind dried at 100° C. (212° F.); also some sugar.

Fig. 208.

Fruit of *Punica Granatum* and longitudinal section.

GRINDELIA, *U. S.*—Grindelia.

California Gum-plant, E.; *Grindelie*, G.; *Grindelia*, Fr.

The dried leaves and flowering tops of *Grindelia robusta* Nuttall, or of *Grindelia squarrosa* (Pursh) Dunal (*Donia s.* Pursh.—Fam. *Compositæ*).

Grindelia is not elsewhere official.

Origin.—These plants are natives of the southern Rocky Mountain region and thence westward and extend into Mexico. *G. squarrosa* is common and abundant, *G. robusta* local and scarce and seldom seen in market. The latter was first used, the former being subsequently introduced as possessing distinct properties. Later, it appeared that they acted alike and they were incorporated under one title. Many physicians still insist upon having that which they first learned to use, and this being scarce, they are commonly supplied with the other, falsely labelled. The drug should be collected during the early period of full bloom.

Fig. 209.

Grindelia: *a*, *G. robusta*; *b*, *G. squarrosa* (Nat.).

Description.—Leaves about 5 Cm. (2 In.) or less long, varying from broadly spatulate or obovate to lanceolate, sessile or clasping, obtuse, more or less coarsely and sharply serrate, often spinosely toothed or even laciniate-pinnatifid, pale yellowish-green or yellow, very smooth, finely dotted, resinous, thick and brittle; heads many-flowered, the involucres of many series of imbricated scales with acute, spreading or recurved tips. The heads of *G. squarrosa* are mostly longer than broad, contracted-campanulate or conical-urceolate; those of *G. robusta* are broader than long, depressed-urceolate. Ray-florets deep-yellow, ligulate, pistillate; disk-florets yellow, tubular, perfect; pappus of 2 or 3 mostly unequal awns, about as long as the disk-florets; odor balsamic, slightly narcotic; taste resinous and gummy, pungently aromatic, somewhat bitter.

Constituents.—The chemistry of Grindelia is as yet unsettled. Both species contain fixed oil, volatile oil, resin, crystalline robustic acid (?), *grindelin* (which Schneegans believes to be a mixture of saponin and another saponin-like glucoside), and possibly a small quantity of a bitter crystalline alkaloid, *grindeline*, which is soluble in water, alcohol, and ether. *G. robusta* contains 2 per cent. of grindelin, and 1.5 per cent. of tannin, while *G. squarrosa* yields only 0.82 per cent. of grindelin and no tannin (Clark).

Pharmaceutical Preparations.—Elixir of Grindelia, N. F.; Fluidextract of Grindelia, U. S. P.

Action and Uses.—Grindelia is a mild stomachic, cardiac tonic, and expectorant. By its stimulating effect upon the vagus nerve and vasomotor center it slows the action of the heart and increases blood-pressure, but is never employed in medicine for this purpose. In large doses it depresses the nervous system, the peripheral sensory nerves being first affected and later the sensory side of the cord, the motor nerves, and motor side of the cord. The drug is excreted by the lungs and kidneys, and occasionally produces some irritation of these organs. It is a useful remedy in the treatment of asthma, whooping-cough, and chronic bronchitis, and is said to be of value in chronic vesical catarrh. As a local application, 1 part of the fluid extract in 10 parts of water, it may be used in treating burns, blisters, herpes zoster, and the dermatitis of "rhus poisoning." The internal dose is from 20 to 60 minims (1.3–4 Cc.). The dried leaves previously impregnated with potassium nitrate may be burned and the fumes inhaled for the relief of asthmatic seizures.

Allied Drugs.—Several other species of *Grindelia*, of the western United States, Mexico, and the Andes, closely resemble the official, and some are used similarly, and even substituted for them. *G. hirsutula* Hook. et Arn. is pubescent or tomentose, the stem often reddish or purplish, the leaves varying between spatulate, oblong, and lanceolate, the upper ones clasping. It is met with along the coast northward to Puget Sound. *G. glutinosa* Dunal has been introduced near the coast of California. It is glabrous, has the leaves rounded at the apex, the involucral scales with short tips, and the pappus of 5 to 8 rigid awns, with thin serrulate edges. It is the *Calancapatle de Pueblo* of Mexico.

Hysterionica Baylahuen owes its medicinal qualities to the resin and volatile oil it contains, the former acting chiefly on the bowels and the urinary passages, and the latter, like the terebinthinates and their products, upon the lungs. It is said to possess an advantage over these medicines in that it does not disorder the stomach and bowels. It has been found useful in chronic diarrhœa, and especially of the tuberculous variety, and in chronic cystitis. The tincture, by its stimulant and protective action, has served (like tincture of benzoin) as a dressing for wounds and ulcers. An infusion of the leaves and twigs (1 : 150) has been advised, and also a tincture (100 : 500) in the dose of 15–25 drops (Baille, *Bull. de Thérap.*, cxvi. 160).

GUAIACI LIGNUM, *Br.*—Guaiacum Wood.

Lignum guajaci, P. G.; *Lignum sanctum* (*vel benedictum, vel vitæ*).—*Lignum vitæ*, E.; *Gayac*, Fr. Cod.; *Guajakholz, Pockholz, Franzosenholz*, G.; *Bois de gayac*, Fr.; *Guayaco, Palo santo*, Sp.; *Legno Santo*, It., Port.

The heart-wood of *Guaiacum officinale*, L. (*G. bijugum* Stokes) or of *G. sanctum* L. (*G. multijugum* Stokes.—Fam. *Zygophyllaceæ*).

Guaiacum wood is official in most pharmacopœias.

Origin.—From small trees of the West Indies and northern South America, the second, and perhaps the other also, extending into southern Florida. They have pinnate leaves, the former of 2 or 3, the latter of 4 or 5 parts of leaflets, and bear an abundance of showy blue flowers. In both, the dark heart-wood is surrounded by a zone of yellowish sap-wood, which is worthless for medicinal purposes, but which is said to be sometimes cut up and stained for mixing with the heart-wood.

Description.—Dark-brown, becoming olive-green upon exposure, capable of a high polish, composed of rings of alternate darker and somewhat lighter tints, resembling annual rings; medullary rays very fine, the vessels scattered, the pith indistinct; very heavy (specific gravity 1.3), hard, tough, splitting irregularly, owing to the much interwoven wood-bundles; occurring commonly in the form of raspings or shavings, which should be free or nearly so from the white sap-wood and should sink in water; odor slight, resinous, aromatic, especially on rubbing or warming; taste somewhat acrid. The shavings acquire a dark blue-green color on being moistened with nitric acid or other oxidizing agent.

Constituents.—The wood contains from 20 to 25 per cent. of resin, considered below, which is the most important constituent, and yields about 3 to 4 per cent. of aqueous extract. Fremy and Urbain (1881) found in the wood, besides 21 per cent. of cellulose, also 36 per cent. of *vasculose*, which is not soluble in ammoniacal copper solution, even after treatment with sulphuric acid. There is no volatile oil.

Action and Uses.—Guaiac wood is prescribed only in decoction (U. S. P. 1870), simple or compound, of which the latter is more efficient. When employed, it is usually in conjunction with other drugs. (For action and uses, see RESINA GUAIACI.)

Allied Species.—*Guaiacum angustifolium* Englemann (*Porliera angustifolia* Gray) is a small tree of southern Texas and Mexico, with a hard, heavy, and irregularly splitting wood of a yellowish-brown color, and used like the preceding.

GUAIACOL, *U. S.*—Guaiacol.

Gaïacol, Fr. Cod.; *Ortho-di-oxybenzene-methyl-ester, Methyl-orthodioxybenzene, Methyl-pyrocatechin, Catechol-monomethylether*, E.; *Guajakol, Brenzcatechinmonomethyl-ester*, G.

Formula, $C_7H_8O_2$ or $C_6H_4(OH)OCH_3$. Molecular weight, 123.13.

One of the chief constituents of creosote, the product from beechwood-tar, obtained by collecting and purifying the fraction of creosote boiling between 200° and 205° C. (392° and 401° F.); or prepared synthetically from either pyrocatechin by methylating, or from ortho-anisidin by diazotizing and boiling. Guaiacol should be preserved in amber-colored bottles, protected from light.—U. S.

Preparation.—Crude guaiacol is obtained by fractional distillation of beechwood-tar creosote, that portion passing over between 200° and 205° C. (392° and 401° F.) being collected; this is treated with ammonia to remove acid compounds, and then again fractionated. The lower boiling fraction is dissolved in ether and treated with a concentrated alcoholic solution of potassium hydroxide, which causes separation of potassium-guaiacol, the latter being insoluble in ether. After thorough washing with ether the salt is crystallized from alcohol, and decomposed by treatment with dilute sulphuric acid; the guaiacol thus set free is again rectified.

Synthetic guaiacol may be obtained by heating in a tightly closed vessel a mixture of equal molecules of pyrocatechin, potassium hydroxide, and potassium methylsulphate, to a temperature of 170° to 180° C. (338°–356° F.), when the following reaction occurs: $C_6H_4(OH)_2 + KOH + KCH_3SO_4 = C_6H_4OHOCH_3 + K_2SO_4 + H_2O$. The resulting guaiacol is removed by solution in alcohol or petroleum ether and purified by recrystallization. It may also be produced by heating a solution of sodium, pyrocatechin, and methyl iodide in methyl alcohol, treating the residue with sodium hydroxide solution, filtering, decomposing with hydrochloric acid, distilling the liberated guaiacol, and finally crystallizing at a low temperature.

A German patent calls for diazotizing ortho-anisidin with nitrous acid, decomposing the newly formed diazo-anisol with sulphuric acid, distilling the liberated guaiacol in a current of steam, and subsequently redistilling and crystallizing.

Properties.—Guaiacol occurs as a colorless, slightly refractive liquid of a strongly aromatic odor, or in the form of colorless crystals. Its specific gravity is 1.140 at 25° C. (77° F.), U. S.; 1.143 at 15° C. (59° F.), Fr. Cod.; 1.117 (Fischer); 1.116–1.133, Swiss P. It boils at 205° C. (401° F.), U. S., Fr. Cod.; 200°–203° C. (392°–397.4° F., Swiss P., and the crystals melt at 28.5° C. (83.5° F.), U. S., Fr. Cod. It is soluble in 60–70 parts of water at 15° C. (59° F.), 60 parts at 20° C. (68° F.) Fr. Cod., 53 parts at 25° C. (77° F.) U. S., and in all proportions in alcohol and ether. It is soluble in acetic acid and in 1 part of glycerin of 1.262 specific gravity, U. S., 7 parts of glycerin of 1.242 specific gravity, Fr. Cod. It is also soluble in chloroform and carbon disulphide. Dissolved in solution of sodium or potassium hydroxide, it forms sodium- or potassium-guaiacol ($C_6H_4OCH_3Na$ or $C_6H_4OCH_3K$), unstable compounds readily decomposed by dilution with much water. If a trace of ferric chloride is added to a 1 per cent. alcoholic solution of guaiacol, an immediate blue color is developed, which changes to emerald-green upon addition of more ferric chloride, the color finally becoming yellowish.

Tests.—If 2 Cc. of guaiacol are shaken with 4 Cc. of petroleum-benzin, the mixture should separate on standing at once into two distinct layers. Turbidity or failure to separate into layers indicates the presence of impurities. 1 Cc. of guaiacol should dissolve in 2 Cc. of sodium hydroxide solution with heat, and on cooling the mixture should congeal to a white saline mass. Coloration, as well as failure to congeal, indicates the presence of impurities. The saline mass thus obtained should dissolve clear in 20 volumes of water (turbidity indicates oily hydrocarbons). 1 Cc. of guaiacol added to 10 Cc. of concentrated sulphuric acid should give a pure yellowish color (a reddish color indicates creosote).—U. S.

The presence of guaiacol in creosote may be determined and estimated colorimetrically by treating a dilute solution of the sample with a few drops of a 4 per cent. solution of cupric sulphate and a few drops of a 4 per cent. solution of potassium cyanide, and comparing the colorations with those produced in solutions containing known amounts of guaiacol under like conditions. In the absence of guaiacol the mixed solution appears greenish by transmitted light, and from reddish-gray to brownish-purple according to the quantity of guaiacol present (Fonses-Diacon).

Action and Uses.—Guaiacol is employed internally as an expectorant and intestinal antiseptic. When locally applied to the skin, it reduces fever and produces local anæsthesia. It has been employed as a substitute for creosote (which see) in the treatment of pulmonary tuberculosis, and as it is eliminated by the bronchial mucous membranes does good by diminishing the cough. It does not, however, have any specific action upon the tubercle bacillus. It may be applied to the tonsils with good result in the early stages of acute follicular tonsillitis, but its application should be cautiously made. Minute doses of guaiacol are sometimes efficacious in the treatment of vomiting. If from 30 to 40 minims (2–4 Cc.) are painted over the skin of the chest, abdomen, or thighs of a febrile patient, it produces a marked fall in temperature, and for this purpose it has been employed in the treatment of typhoid fever and other acute febrile conditions. It has been locally employed for reducing the fever of tuberculosis, but in any of these conditions it may produce excessive sweating and depression. Guaiacol may be locally applied for the relief of superficial neuralgias, or it may be hypodermically injected in 2-minim (0.10 Cc.) doses when the pain is in deep-seated nerves. This remedy has been employed by painting it over the scrotum every other day for the relief of orchitis. For this purpose it may be diluted with 3 parts of glycerin or lanoline. The beginning internal dose is 2 minims (0.10 Cc.), which may be gradually increased to 10 or 15 minims (0.60–1 Cc.), 3 times a day.

DERIVATIVES OF GUAIACOL.

The following derivatives of guaiacol are of more or less interest to physicians and pharmacists.

Guacamphol.—This name has been applied to the camphoric acid ester of guaiacol. Its composition is expressed by the formula $C_8H_{14}(CO_2.C_6H_4.OCH_3)_2$, and it is obtained by the action of camphoric acid chloride on sodium-guaiacol. It occurs as white odorless, tasteless needles, which are insoluble in water, but soluble in alcohol and chloroform. Has been recommended for the relief of the night-sweats of phthisis. Dose, 3 or 4 grains (0.20–0.25

Guaiacol Benzoate, *known also as Benzosol and Benzoyl-guaiacol.* $C_6H_4(OCH_3).C_6H_5CO_2$. —This compound is made by heating an alcoholic solution of potassium-guaiacol with the requisite amount of benzoyl chloride, and purifying the resulting benzoyl-guaiacol by recrystallization from alcohol. It is a colorless, odorless, and tasteless powder, almost insoluble in water, but readily soluble in ether, chloroform, and hot alcohol. It melts at 56° C. (132.8° F.). With concentrated sulphuric acid it forms a lemon-yellow colored solution, but ferric chloride does not produce the characteristic color reaction in an alcoholic solution. Benzosol has been given in doses of from 4 to 8 grains (0.25–0.50 Gm.) in the treatment of pulmonary tuberculosis.

If benzyl chloride be made to act on sodium-guaiacol, a different compound is produced, known as *guaiacol-benzyl ether* or *pyrocain*, and having the composition $C_6H_4(OCH_3)OCH_2C_6H_5$. It must not be confounded with the former.

Guaiacol-bisulphonate of Quinine, *or Guaiaquin.* $(C_6H_4O_2CH_3HSO_3)_2C_{20}H_{24}N_2O_2$.—A yellowish crystalline powder soluble in water, alcohol, and dilute acids. It is an acid salt, having a bitter taste and containing 44.29 per cent. of anhydrous quinine alkaloid.

Guaiacol Carbonic Acid. *Methoxysalicylic acid.* $C_6H_4(OH)(OCH_3)COOH + 2H_2O$.—It is prepared by a patented process in a manner somewhat similar to that of the salicylic acid manufacture; carbon dioxide is made to act on sodium-guaiacol previously heated, whereby guaiacol-sodium carbonate is formed; continued heating converts this into sodium guaiacol-carbonate, from which the free acid is obtained by acidifying with hydrochloric acid, and finally recrystallizing from hot water or diluted alcohol. It is a white, odorless crystalline powder of a bitter taste, difficultly soluble in cold, but readily in hot water, also in alcohol and ether, and likewise in a solution of sodium bicarbonate. The anhydrous acid melts at 148°–150° C. (298.4°–302° F.). A cold aqueous solution of the acid is colored blue by solution of ferric chloride. This compound should not be confounded with guaiacol carbonate. Guaiacol carbonic acid and its salts have been recommended as antiseptics and antirheumatics.

Guaiacol Cinnamate, *Styracol, Cinnamyl-guaiacol.* $C_6H_4(OCH_3)C_9H_7O_2$.—If equal molecular weights of guaiacol and cinnamyl-chloride are brought together at ordinary temperature, and after 2 hours heated for some time on a water-bath, hydrochloric acid is formed and also cinnamyl-guaiacol. The salt is crystallized from boiling alcohol. It occurs as colorless needle-shaped crystals which melt at 130° C. (266° F.). It is insoluble in water, but soluble in alcohol, chloroform, and acetone. Styracol is prescribed principally in catarrhal affections of the digestive tract and in the treatment of phthisis.

Guaiacol Phosphate, *Phosphoric guaiacyl-ether.* $(C_6H_4OCH_3)_3PO_4$.—Prepared by the action of phosphorus oxychloride upon sodium-guaiacol. In colorless crystals melting at

98° C. (208.4° F.), insoluble in water and alcohol, but soluble in ether, chloroform, and acetone. It is used as an intestinal antiseptic and in hectic fever.

Guaiacol Phosphite, *Phospho-guaiacol, Phosphite of guaiacyl-ether.* $P(OC_6H_4OCH_3)_3$.—White crystalline powder, quite odorless, having a warm, but not caustic taste, melting at 77.5° C. (171.5° F.), soluble in water (distinction from guaiacol phosphate), alcohol, ether, acetone, chloroform, toluene, fixed oils, slightly soluble in oil of turpentine and glycerin, and contains 92.36 per cent. of guaiacol and 7.64 per cent. of phosphorus. Guaiacol phosphite possesses about the same medicinal properties as guaiacol, but is thought by some to be less irritating. Dose, 15 to 30 grains (1–2 Gm.).

Guaiacol Salicylate, *Guaiacol-salol,* E. $C_6H_4OCH_3.C_7H_5O_3$.—This compound is analogous to salol, and is the result of the action of phosphorus oxychloride on a mixture of sodium-guaiacol and salicylate, when guaiacol salicylate, sodium chloride, and sodium phosphite are formed. It is a white, crystalline, odorless and tasteless powder, insoluble in water, but soluble in alcohol, ether, and chloroform. It melts at 65° C. (149° F.). An alcoholic solution of the salt is colored wine-red by ferric chloride. It is used as an intestinal antiseptic.

Guaiacol Succinate. $C_4H_4O_4(C_6H_4OCH_3)_2$.—Fine, silken, crystalline needles, melting at 136° C. (276.8° F.), insoluble in water, difficultly soluble in alcohol and ether, and easily soluble in chloroform, acetone, petroleum ether, and hot toluene. It is prepared by the action of phosphorus oxychloride upon the molecular equivalent of a mixture of guaiacol and succinic acid, or by the action of succinyl chloride upon sodium-guaiacol at a low temperature.

Guaiacol Valerianate, *Geosot.* $C_6H_4.OCH_3.C_4H_9CO_2$.—Prepared by the action of valeryl chloride upon sodium-guaiacol. A yellowish oily liquid, having an odor suggestive of guaiacol and valerianic acid, specific gravity 1.037, soluble in alcohol, ether, benzene, and chloroform, and difficultly soluble in water. It boils at 245°–265° C. (473°–509° F.).

Guaiamar, *or Guaiacolglycerylester.* $C_6H_4OC_3H_7O_2.OCH_3$.—It is obtained by the action of guaiacol on anhydrous glycerin, and occurs as a dry white crystalline powder, having a bitter, aromatic taste, melting at 75° C. (167° F.), and soluble in 20 parts of water, also in alcohol, chloroform, ether, and glycerin. It is used as a substitute for guaiacol.

Guaiperol, *or Piperidine guaiacolate.* $C_5H_{11}N(C_7H_8O_2)_2$.—Prepared by dissolving 85 parts of piperidine and 248 parts of guaiacol in benzene or petroleum ether and allowing the solution to crystallize. Colorless prisms or crystalline needles soluble in 30 parts of water and soluble in alcohol and chloroform.

GUAIACOLIS CARBONAS, *U. S.*—Guaiacol Carbonate.

Duotal, E.; *Carbonate de Gaïacol,* Fr.; *Guajacolkarbonat, Kohlensäure-Guajacyläther,* G.

Formula, $(C_6H_4OCH_3)_2CO_3$ or $(C_6H_4(OCH_3)O)_2CO$. Molecular weight, 272.05.

Preparation.—This compound is obtained by slowly passing carbonyl chloride, $COCl_2$ (phosgene gas), into guaiacol previously dissolved in caustic soda solution, when sodium chloride and guaiacol carbonate will be formed. The latter, being insoluble, is separated and washed with caustic soda solution, and finally crystallized from alcohol.

Properties.—Guaiacol carbonate occurs as a white crystalline powder, of neutral reaction, nearly void of odor and taste. It is insoluble in water, soluble at 25° C. (77° F.) in 48 parts of alcohol, 1.5 parts of chloroform, and 13 parts of ether; readily soluble in hot alcohol and benzene, slightly soluble in glycerin and fixed oils. It contains 91.5 per cent. of guaiacol and melts at 84°–87° C. (183.2°–188.6° F.). When in contact with alcoholic solution of potassium hydroxide it is at once decomposed, and from the solution so obtained guaiacol may be separated on addition of an acid.—U. S.

Test.—The alcoholic solution of guaiacol carbonate does not yield a characteristic color on addition of solution of ferric chloride (absence of free guaiacol).—U. S.

Action and Uses.—The action of this substance when taken internally is practically the same as that of GUAIACOL (which see), except that it is less liable to derange the stomach. It is employed as an expectorant in the treatment of tuberculosis and chronic bronchitis, and as it is decomposed into guaiacol in the intestine is frequently given as an intestinal antiseptic in the treatment of typhoid fever and intestinal indigestion. It may be given in powder or capsule in doses of from 2 to 10 grains (0.10–0.60 Gm.), 3 times daily.

GUAIACUM, *U. S.*—Guaiac.

Guaiaci resina, Br. (U. S., 1890); *Resina guaiaci—Guaiacum resin,* E.; *Guajakharz,* G.; *Resine de gayac,* Fr. Cod.; *Resina de guayaco,* Sp.

The resin of the wood of *Guaiacum officinale* L. or of *G. sanctum* L. (see GUAIACI LIGNUM).

Guaiac resin is official in most pharmacopœias.

Origin.—The resin is obtained partly as a natural exudation or from incisions, partly by setting fire to a billet of the wood which has been grooved or pierced lengthwise on the side, the resin as it melts running from the opening.

Description.—The resin is in separate or agglutinate tears, varying in size from 6 to 25 Mm. (¼ to 1 In.) in diameter, or more generally in irregular masses, intermixed with fragments of wood and bark. It is of a greenish- or reddish-brown color, brittle, breaks with a somewhat conchoidal fracture having a glassy luster, and is transparent in thin splinters. It yields a whitish powder which turns rapidly green on exposure to the air, has the specific gravity 1.2, fuses at about 85° C. (185° F.), emitting an agreeable odor suggesting that of vanilla, and at a higher temperature gives off irritating vapors. Its taste is not strong, but is distinctly acrid. The resin is soluble in caustic potassa and in nearly all of the solvents for resins, except carbon disulphide, benzene, and oil of turpentine; it is nearly insoluble in benzin and fats. The solutions, as well as the powder, are colored green or blue by nitric acid, chlorine, ferric chloride, and other oxidizing agents; the same color is produced by ozone and upon the inner surface of the paring of a raw potato. Guaiac resin should be soluble in alcohol, leaving but a slight residue; sometimes it is very impure, containing as much as 16 per cent. of wood and bark. Its alcoholic solution has a slight acid reaction, and when dissolved in solution of potassium or sodium hydroxide it is reprecipitated on the addition of an acid.

Hirschsohn states that guaiac resin should yield to petroleum benzin not more than 2 to 4 per cent. of its weight; colophony and damar dissolve to the extent of 77 to 90 per cent. The so-called *Peruvian guaiac resin*, of undetermined origin, has an odor resembling a mixture of rue and anise, and about 42 per cent. of it is soluble in benzin. The alcoholic solution of guaiac resin is precipitated by lead acetate (difference from carana resin), and with potassium hydroxide solution gives a precipitate easily soluble in excess of the alkali (difference from colophony).

Constituents.—The resin yields about 10 per cent. of guaiaretic acid ($C_{20}H_{26}O_4$), an equal quantity of guaiac beta-resin ($C_{20}H_{24}O_4$?), 50–70 per cent. of alpha-resin or guaiaconic acid ($C_{20}H_{24}O_5$ or $C_{19}H_{20}O_5$), a slight quantity of guaiacic acid ($C_{12}H_{16}O_6$), guaiac-yellow, 4–9 per cent. of gum and a little mineral matter. Paetzold finds that both wood and resin of Guaiac contain a saponin which he believes to be the active constituent. It is much more abundant in bark and sap-wood, which the author thinks may be substituted to advantage. This idea is, to say the least, at variance with known facts regarding the action of Guaiac.

Guaiac-yellow is a feeble acid, crystallizing in yellowish quadratic plates, bitter, and soluble in alcohol, ether, and alkalies, but not readily soluble in water, chloroform, or dilute acid.

Guaiac beta-resin is soluble in alcohol and acetic acid, but insoluble in ether, chloroform, or carbon disulphide. On destructive distillation, guaiac resin yields guaiacene (guaiol or tiglic aldehyde, C_4H_7COH), guaiacol ($C_7H_8O_2$), creosol ($C_8H_{10}O_2$), and pyroguaiacin ($C_{18}H_{18}O_3$).

Guaiaretic acid occurs in colorless concentrically grouped needles, insoluble in water and ammonia, but soluble in solution of potassium and sodium hydroxides, acetic acid, alcohol, chloroform, ether, and carbon disulphide. It is not colored blue by oxidizing agents. Heated with hydrochloric acid, it yields pyrocatechin and methyl chloride; fused with potassa it yields protocatechuic acid. Its alkaline salts are crystalline, those of the alkaline earths amorphous.

Guaiaconic acid is the substance which forms the blue color with oxidizing agents. It is tasteless, odorless, brownish, amorphous, insoluble in water, and easily soluble in alcohol, ether, chloroform, and acetic acid. Its reaction is not acid, but it forms soluble amorphous salts with alkalies, and insoluble salts with the heavy metals.

Guaiacic acid forms colorless needles, soluble in water, alcohol, and ether.

Pharmaceutical Preparations.—Ammoniated Tincture of Guaiac, U. S. P.; Compound Tincture of Guaiac (Dewees'), N. F.; Glycerite of Guaiac, N. F.; Mixture of Guaiac, N. F.; Tincture of Guaiac, U. S. P.

Action and Uses.—Guaiac is diaphoretic, stimulant, alterative, and in large doses purgative. As a cure for constitutional syphilis it has practically been abandoned, although formerly it ranked among the first remedies in the treatment of this condition. It is occasionally employed in amenorrhœa and dysmenorrhœa resulting from feeble uterine circulation, but other more valuable remedies have nearly replaced it. Guaiac may be used in chronic rheumatism and in gouty conditions, but its administration in these is of

doubtful efficacy. Internally the drug has been employed in simple tonsillitis and in diphtheria; in the former condition it may be of some value, but in the latter it is worthless.

Resin of guaiac is usually given in the dose of from 10 to 30 grains (0.60–2 Gm.). Both the ammoniated tincture and the tincture of guaiac are given in the dose of from 10 to 60 minims (0.6–4 Cc.), and is frequently combined with an equal amount of solution of potassium hydroxide in order to render it miscible with water. In order to render it more agreeable the following formula may be employed: tincture of guaiac, 15 minims; solution of potassium hydroxide, 15 minims; glycerin or syrup, 1 drachm; and cinnamon water sufficient to make 1 ounce (A. H. F. Cameron, in *British Medical Journal*).

A soap of guaiac made by saturating a solution of potassium hydroxide diluted with twice its weight of water, with resin of guaiac, and evaporating to a pilular consistency, is sometimes employed in the dose of from 10 to 20 grains (0.6–1.3 Gm.).

GUARANA, *U. S.*—Guarana.

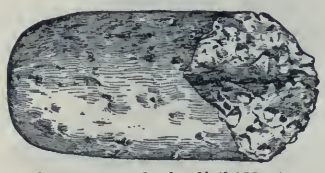
Pasta guaranæ.—*Guarana*, Fr., G., Sp.; *Uarana*, Port.; *Paullinia*, Belg., It.

A dried paste consisting chiefly of the crushed seeds of *Paullinia Cupana* Kunth (*P. sorbilis* Mart.—Fam. *Sapindaceæ*), yielding not less than 3.5 per cent. of its peculiar alkaloid.

Guarana is official in a number of pharmacopœias. The U. S. P. demands that when assayed by the process given below, it shall yield not less than 3.5 per cent. of its peculiar alkaloidal principle. The Italian requires that it retain 5 per cent., the Swiss at least 3 per cent., of caffeine.

Origin and Preparation.—The seeds are borne upon a stout, woody, tendril-bearing, high-climbing vine, related to the common balloon vine (*Cardiospermum*) of the gardens, native of Brazil, and there largely cultivated, especially along the Itenez River. It is cultivated upon trellises, or tied to stout stakes like vines in a vineyard. The globular fruit splits into 3 divisions, exposing 3 rounded seeds of the size of filberts. These, which look like large filberts, are washed free from a mucus-like coating and dried or slightly roasted, the kernel being thus caused to shrink from the testa. The brittle testa is then broken up by beating and is winnowed out. The kernels are broken up in wooden mortars, usually the hollowed stump of a tree, with wooden pestles, contact with iron causing blackening of the product. The best product is broken only sufficiently fine to allow of proper moulding into forms after the addition of a little water. A little tapioca is often added to favor cohesion, and, rarely, the amount of this is increased for purposes of adulteration. After being moulded into rolls, or other forms, it is laid upon wooden gratings, usually of bamboo strips, and slowly dried by fires built underneath. If dried too rapidly, if the wrong fuel be employed, or if the fire be not properly managed, the flavor is impaired; while if the process be too slow, moulding or fermentation is likely to occur. The curing process is therefore quite a critical one, and is usually not performed by the growers, but as a separate industry. Many lots are spoiled, and these are usually exported for medicinal purposes, those who purchase it for use as a beverage selecting as carefully as do our tea or coffee connoisseurs. Guarana constitutes the habitual beverage of millions of people in the Amazon valley. It is usually or frequently drunk suspended in cold water after being grated or filed from the roll or cake, about 1 or 2 teaspoonfuls to a cup of water. The guarana-habit is very similar to the tea- or coffee-habit. We have seen those who used it to excess suffer from a peculiar palsy, the limbs shaking violently under any excitement, but subject to control, the agitation gradually and perfectly ceasing under effort.

Fig. 210.



Guarana, end of roll (½ Nat.).

Description.—In subglobular or elliptical cakes or cylindrical rolls, hard and heavy; outer surface somewhat shortly nodular, smooth, slightly lustrous, deep chocolate-brown; rather brittle, the fracture uneven, often fissured in the center, of a deep flesh-color or pale reddish-brown, showing numerous coarse, angular, lustrous fragments of seeds partly invested with blackish-brown integuments; odor slight, peculiar, a little resembling that of chocolate; taste very astringent, somewhat bitter, afterward sweet, especially when chewing is followed by a swallow of water.

Constituents.—Besides caffeine and paullinitannic acid, Guarana contains gum,

starch, and an acrid, green, fixed oil, volatile oil, and saponin. Caffeine (guaranine) exists to the extent of from 3 to 5 per cent., probably in the form of tannate. The 25 per cent. or more of tannin, *paullinitannic acid*, gives precipitates with ferric salts (green-brown), gelatin, and most alkaloidal salts, but no precipitate with tartar emetic or copper sulphate. It reduces salts of silver and gold. It is evidently related to catechutannic acid. A very small amount of catechin was extracted by Schaer, and named *Paullinia catechin*.

Valuation of Guarana.—Put 6 Gm. of Guarana powder into a flask and pour upon it 120 Cc. of chloroform and 6 Cc. of ammonia water. Shake well at intervals for half an hour, and let stand for 4 hours. Pour off 100 Cc. of the liquid through a filter into a measuring cylinder, and transfer it therefrom to a flask, and distil off all the chloroform on a water-bath. Dissolve the residual alkaloids in a mixture of 2 Cc. of normal sulphuric acid and 20 Cc. of warm distilled water. Let cool and filter into a separator, rinse the beaker and filter with distilled water, add 10 Cc. of chloroform, 2 Cc. of ammonia water, and shake for a minute or two. Draw off the chloroformic solution into a tared flask and repeat the extraction 3 times more with 10 Cc. of chloroform, drawing each portion off into the tared flask. Distil off the chloroform, and when dry, add 2 Cc. of ether and evaporate this on a water-bath very carefully to avoid decrepitation. Dry the residue to constant weight on a water-bath and weigh. The weight found multiplied by 20 will give the percentage of total alkaloids in the drug.

Pharmaceutical Preparations.—Elixir of Guarana, N. F.; Fluidextract of Guarana, U. S. P.

Action and Uses.—The effects of guarana are due chiefly to the alkaloid which is present (see Caffeina), although it possesses in addition astringent and tonic properties. It was formerly used in the treatment of diarrhœa and dysentery, urethritis, leucorrhœa, and uterine oozing; but at present it is employed principally in the treatment of neuralgia, menstrual headache, and headache following a prolonged debauch. The powdered drug may be given suspended in sweetened water in doses of from 1 to 2 drachms (4–8 Gm.), or in the form of a fluidextract or elixir in equivalent amounts.

Allied Species.—Of the 120 or more species of *Paullinia*, no other is known to possess the properties of Guarana. The stems of a number are used as fish poisons, by virtue of their contained saponin. One of these, used under the name *Timbo*, has been observed by the writer to color the streams and pools intensely black, when so used. Martin reported the alkaloid *timbonine* in *P. pinnata*, which is probably the species last referred to.

Sapindaceæ.—This small family of some 600 species of woody plants, is distinguished for the frequency and abundance with which saponin occurs among its members. The fruits of various species of *Sapindus*, especially, are used in many tropical or warm regions as a soap-substitute under the name of *Soap-berries*, and are poisonous. These are globular or globoidal fruits, mostly about a half inch in diameter. The pericarp is either parchment-like or somewhat gummy and translucent, and loosely encloses a solitary large seed. The normal structure calls for 3 such carpels to form a fruit, but almost always there is but 1, sometimes 2, and rarely 3 or even 4. The pericarp contains the saponin, with formic and tartaric acids, and is bitter and acrid. The seeds commonly contain about 30 per cent. of a butyraceous fat. *S. marginatus* W. and *S. Saponaria* L., of our southern and southwestern districts and extending into Mexico, are there known as *Wild China tree*, and the fruit has been used, apparently only because of its resemblance to Azedarach fruit, as an antiperiodic. *S. Mukorossi* Gærtn. (*S. abruptus* Lour.; *S. detergens* Roxb.) is the East Indian *Dodan* and the Chinese *Wu-hwan-tsze*. *S. trifoliatus* L. (*S. laurifolius* Vahl.; *S. Rarak* DC.; *S. Saponaria* Burm.; *S. emarginatus* Vahl.; *Dittelasma Rarak* Hook.) is the Indian *Ritha* or *Aritha*, *Arishta* or *Pheuila*. *S. esculenta* St. Hil., the Brazilian *Pittomba*, the root known as *Caminhoa*, is said to yield an edible pericarp, but a poisonous seed and root. The fruit of *Pancovia Delavagi* Franch., the *Chinese Tie-ouassie-tsze-chou*, is widely used. The family yields many edible fruits, typified by the delicious East Indian *Nephelium* (*Li-chi*, *Tan-li*, *Rambutan*, *Rampostan*, *Chinese fruit*, or *Dragon's eye*). A number of *Dodonæas* also contain saponin and are used medicinally, and some are poisonous.

GUTTA-PERCHA, *P. G.*—Gutta-percha.

Getah-pertcha, *Gutta-percha depurata*, *Gutta-taban*, *Gummi plasticum*.—*Gutta-percha*, Fr., G.

The concrete milk-juice of *Palaquium Gutta* (Hook. f.) Burck (*Isonandra G.* Hook. f.; *Dichopsis G.* B. et H.—Fam. *Sapotaceæ*). Doubtless, a part of the commercial supply is collected from other species, and it is even claimed that most of it is

so. Thus, besides the special varieties mentioned under *Allied Substances*, commercial Gutta-percha is said to be derived in part from the following species: *Payena Leerii* Kurtz (*Ceratophorus L.* Hassk.); *Bassia sericea* Bl.; *Omphalocarpon procerum* Pal.; *Palaquium Borneense* Pierre; *Sideroxylon ferrugineum* H. et A. (*S. attenuatum* DC.), of the Philippines.

Origin and Collection.—The Taban is a good-sized, sparingly branched evergreen tree of southeastern Asia and the neighboring islands. It is much less abundant than formerly, owing to the destructive methods of collection, but, upon the other hand, it has been to some extent introduced to cultivation. Earnest efforts are now being made to acclimatize it in France and other countries, as a serious scarcity appears impending under the continuation of existing conditions. Various methods for collecting it, all more or less seriously destructive, have been depended on. The commonest is to fell the tree and at once encircle the trunk and large branches with notches cut through the bark, at short distances apart, the exuding milky juice trickling into cups set underneath. The bark is also removed in strips and the milk scraped from the surface of the wood. It is estimated that the amount obtained (from 6 to 20 pounds) is but a very small part of that in the tree, most of which can, by suitable means, be extracted from the ground bark, twigs, and leaves. Experiments have even been made, with fair success, in extracting it from the fresh leaves, so gathered from the living tree as not to injure it. It can be dissolved out of the ground-leaves by carbon disulphide (which is said to injure the product), by hot toluene or light petroleum spirit, the last probably being, all things considered, the most feasible method. By present methods, considerable vegetable tissue is retained in the mass, often involving a considerable loss of weight upon purification.

Description.—Gutta-percha is grayish or yellowish, frequently with red-brown streaks from fragments of bark and other impurities. It is hard and rather leathery or horny, in thin pieces somewhat flexible, is readily cut with a knife, between 45° and 60° C. (113° to 140° F.) is sufficiently soft to be rolled into sheets, is quite plastic at 65° C. (149° F.), and very soft at the temperature of boiling water. Its specific gravity, in bulk. is about 0.98, but it is heavier than water after the removal of all air-cavities. It is insoluble in water, alcohol, acids, alkalies, and fixed oils, but dissolves in boiling ether, chloroform, benzene, coal-tar oils, carbon disulphide, and oil of turpentine. On evaporating these solutions it is left behind with its original properties more or less nearly unimpaired. It is purified for dental and other purposes by agitating its solution with gypsum. If purified by treatment with water and hydrochloric acid, and then repeatedly dissolved in boiling ether and washed with cold ether and alcohol, a fine white powder is obtained of the composition $C_{20}H_{32}$, which is the composition of pure gutta. It absorbs and combines with oxygen from the air, yielding white crystalline resin, Payen's *albane*, $C_{20}H_{32}O$, and yellow amorphous *fluavil*, $C_{20}H_{32}O_2$, both of which are contained in commercial gutta-percha sometimes to the amount of 20 per cent. Subjected to dry distillation, various gases, water, and volatile acids are obtained, and two oils, one yellow, the other red-brown, both of the composition $C_{10}H_{16}$.

Pure gutta-percha is inodorous and tasteless; ignited, it burns with a bright flame. Its mixture with caoutchouc is readily vulcanized, and after the incorporation of insoluble earthy or metallic compounds is largely used in the preparation of various instruments.

Exposed to the air, with its changes of temperature, and especially to the rays of the sun, gutta-percha quickly deteriorates into a resinous, easily crumbled substance, but well preserved under salt or fresh water it is practically indestructible, scarcely any change having been observed in the gutta-percha of submarine cables after the lapse of half a century. Suspended in tunnels, its life is estimated at about 10 years; in underground pipes, about 20 years. In certain parts of the British Isles a tiny insect (*Templetonia crystallina*) has been found to eat off gutta-percha coverings.

Pharmaceutical Preparation.—Solution of Gutta-percha, N. F.

Action and Uses.—Gutta-percha possesses no medicinal properties, and is never employed in internal medicine. Externally, in the form of the Liquor Gutta-perchæ, it has been recommended as a substitute for collodion in excluding air from abrasions and fissured nipples, and for approximating the edges of incised wounds. The solution when locally applied is also said to be advantageous in the treatment of lepra, psoriasis, eczema, and other forms of skin disease. This substance is also employed in dentistry as a temporary filling for carious teeth, particularly during pregnancy. Gutta-percha is largely used in the manufacture of splints and other surgical appliances, and is of especial value because after immersion in hot water it may be moulded into any desired form.

Allied Substances and Substitutes.—The following very similar substances should perhaps be regarded as varieties of Gutta-percha: *Getah* or *Gutta maran* is said to come from *Payena Bawun* Scheffer; *G. Natu* from *P. Mentzelii* R. et Sch.; *G. Putih* or *G. Sundek* from a *Palaquium*, probably *P. ellipticum* (*Dichopsis e.* B. et H.). Two different substances are known in the East Indies as *G. Soosoo* (*Susu*). That of Perak is a *Gutta-percha*, but firmer than the ordinary, and is apparently from *Palaquium Sussu* Engl. That of Borneo is more like rubber, as is *G. Rambou*, a reddish-brown variety, doubtless from a *Ficus*, said to be *F. elastica* Roxb. *G. Singarip* is a soft, wet, spongy mass, more like rubber, and believed to come from an *Apocynaceous* climber. An artificial substitute, called "French Gutta-percha," has been obtained from an aqueous extract of birch bark, made by boiling.

Balata, or Gum Balata, is collected precisely as is Gutta-percha, from *Mimusops Balata* Gærtn. and *M. Schomburgkii* (Pierre) Rusby (*M. Balata Schomburgkii* Pierre), inhabiting Guiana and the adjacent northeastern portion of South America. The trees grow somewhat larger than the Gutta-percha and yield an edible sweet fruit of the size of a plum. The Balata is somewhat tougher and more flexible than Gutta-percha, yet more resinous, the resin being softer. It becomes soft and plastic in hot water (at 50° C.; 122° F.), hardening at once, but preserving its elasticity, when thence plunged into cold water. It melts at 150° C. (302° F.). About one-fourth of the ordinary article is dirt and water, about 41 per cent. gutta, and 35 per cent. resin. Its annual production is probably about four or five million pounds.

Chicle.—Somewhat like Gutta-percha in its general nature is Chicle, or Gum Chicle, now the principal substance used in the manufacture of chewing-gum, and derived from *Achras Sapota* L. (*Sapota Achras* Mill., the *Sabodilla*, *Sapotilla*, *White sapota*, *Naseberry*, or *Ya*, of tropical America, where this tree supplies one of the most important edible fruits. Although the substance is collected in many parts of Mexico and Central America, the principal sources of supply are in Yucatan. The milk-juice is obtained from incisions made in the bark, performed with great care and by experienced persons. Tapping may occur once in 3 years without great danger to the life of the tree. The raw milk is boiled and then allowed to harden in brick-shaped moulds. If carefully prepared, it usually turns out of a white or whitish color, though that of some trees is said to turn out red in any case, a result which will also occur if the ordinary milk be overcooked. If undercooked, it retains a large percentage of water, proportionately reducing its value. Various devices for adulterating substances of this class are resorted to. Chicle gum of good quality is whitish, of firm, tenacious, somewhat elastic consistency, yet may be crumbled between the fingers; somewhat aromatic and nearly tasteless. It becomes plastic on chewing. Examined by Prochozka and Endemann, 75 per cent. was found to be a resin, 9 per cent. calcium oxalate (with traces of magnesium sulphate).

From the seed of the Sapodilla has been extracted the glucoside *sapotin* ($C_{29}H_{52}O_{20}$), soluble in water, somewhat in alcohol, insoluble in ether, benzene, or chloroform.

GUTTIFERÆ.—The Gamboge Family.

This family, even inclusive of the *Hypericaceæ*, now generally regarded as pertaining to it, comprises only about 500 species. The Guttiferæ proper are tropical plants, commonly parasitic during at least a part of their existence, and containing milky juices. These juices, typified by Cambogia, are commonly irritant purgatives. Besides those named, the following yield substances similar to and used like *Cambogia: Garcinia Cowa* Roxb. (*G. Roxburghii* Wight; *G. umbellifera* Roxb.; *G. Wallichii* Chois.; *G. lobulosa* Wall.; *Oxycarpus Gangeticus* Ham.); *G. cornea* Roxb.; *Clusia macrocarpa* Spreng. (*Quapoya Parapanari* Aubl.; *Clusia P.* Chois.), and *Stalagmites ovalifolia* R. Br. (*Xanthochymus v.* Roxb.; *Cambogia Gutta* Burm.). Several of the juices are balsam-like and are used as Copaiba-substitutes, notably those of the West Indian *Calophyllum Calaba* Jacq., *Clusia flava* Jacq. (the *Fat pork monkey apple*), *Rheedia acuminata* Planch. (*Verticillaria a.* R. et P.; *V. Peruviana* Don), which yields the *Balsam Maria*, *Calophyllum apetalum* Wight (*C. Calaba* L.; *C. spurium* Chois.), *C. Tacamahaca* W., *Rheedia Madruno* Pl. et Tr. (*Calophyllum M.* H. B. K.), the balsams of the three last being known under the name *Tacamahaca*. The milk-juice of *Clusia galactodendron* is said to be used in Colombia as a milk-substitute, under the name *Kafa*, though the identity of the plant is doubtful. The East Indian *Calophyllum Wightianum* Wall. (*Sira punnai*) and *C. tomentosum* Wight (*C. elatum* Bedd.), the *Sirpoon*, yield gums. The juice of *Platonia insignis* Mart. (*Morronobea esculenta* Arruda), of tropical America, is converted into a rubber. The bark of the Peruvian *Clusia Pseudochina* Poepp. is used as a Cinchona-substitute.

A number of fats extracted from seeds pertaining to this family have more or less important local uses, and some are even of commercial importance. *Kokum butter* is thus obtained from *Garcinia Indica* Chois. (*G. purpurea* Roxb.; *Brindonia I.* Thouars). This fat is moulded into cakes or balls and is very extensively traded in. The natives use it as a food, the Europeans as an application, either in its own form or as an ointment-base, for which its high melting-point well adapts it in that country, it being "friable in the hottest weather"

(Dymock et Hooper). *Kanya butter* is a similar fat from the seeds of *Pentadesma butyracea* Don, of western Africa.

Several seeds of this family resemble Kola, and are used as substitutes for, or even as adulterants of it. This is true of the seed last-named, which is said to contain a poisonous resinous constituent. *Garcinia Kola* Heckel, of the same region, is also used as a Kola-substitute under the name of *False, Male,* or *Bitter kola.* Its only important constituents appear to be tannin and resin. On some accounts, especially for its reputed, and probably fanciful aphrodisiac properties, it is preferred to Kola by the natives.

. The seeds of *Mammea Americana* L. and the fixed oil from those of *Calophyllum Inophyllum* L. (*Balsamaria Onophyllum* Lour.) are used as adulterants. The latter bears a great many native names.

Mangosteen or Mangostan.—This is the product of *Garcinia Mangostana* L. The rind is a popular astringent, and contains resin, tannin, and the peculiar neutral body *mangostin,* crystallizable in golden-yellow tasteless scales, soluble in alcohol and ether, not in water, and with ferric chloride giving a dark-green color which is removed by acids.

The dried rind has been an article of commerce as a substitute for Bael fruit. It occurs in irregular fragments, somewhat resembling pomegranate rind, the outer surface being covered with a thin separable layer, of a red-brown color, the inner surface more commonly yellowish-brown and slightly ribbed longitudinally. The bark and leaves are similarly used as astringents.

The fruits of *G. Kydia* Roxb. and *G. pedunculata* Roxb. are similar but inferior to the Mangosteen.

The fruit of *G. Indica, Red mango, Kokum fruit,* or *Garcinia à fruit acide* (Fr.), is a popular antiscorbutic, and is largely sold for use as an ingredient of curry, either fresh or in the form of the dried pulp, to which a little salt is added. Its juice is sometimes used as a mordant. Both the leaves and the bark are astringent, and the former is acid, like the fruit. The fruit of *G. Zanthochymus* Hook. f. is similarly acid and its pulp is similarly used.

At least a score of species of *Garcinia* have been reported as yielding edible products. *Mammea Americana* L. yields the tropical American *Mammee apple* or *South American apricot,* a large but inferior edible fruit. An alcoholic beverage or wine is obtained from it. Other species yielding edible fruits are the following: *Platonia insignis,* the *Pacury-uva* of tropical America, its seed oily like the almond; *Rheedia lateriflora* L., and several other tropical American species of Rheedia; *Ochrocarpus Africanus* Oliv. (*Mammea A.* Sabin.); *O. longifolius* B. et H. (*Calysaccion l.* Wight.), the *Indian suringi,* its aromatic buds employed somewhat like cloves, under the names *Nagkassar puniga* and *Tamra naghe-sur; O. Madagascariensis* DC. (*Tovomita M.* G. Don); *Macoubea Guyanensis* Aubl. and *Mesua ferrea* L., the Indian *Naga-kesara,* etc., its petals being used as an aromatic and the fixed oil of its seeds as an antirheumatic. The fruit of *M. speciosa* Chois. yields a similar oil, similarly employed, and its fruit is purgative.

Many species of *Calophyllum* yield edible fruits. *C. Inophyllum* is an important medicinal plant of the Orient, under the names *Undi, Punnagamu,* etc. Its bark is used as a diuretic and emmenagogue.

Hypericaceæ.—This group of beautiful flowering plants, formerly regarded as a distinct family, contains a number of species which are mildly medicinal and some of which have been extensively used.

Hypericum, St. John's wort, Cammock, Rosin rose, or *Touch and heal* (E.), *Hartheu* or *Johanniskraut* (G.), *Millepertuis* or *Cassediable* (Fr.), *Hypericon* (Sp.), is the herbage of *H. perforatum* L. (*H. vulgare* Lam.; *H. officinale* Gater.; *H. officinarum* Crantz), used under the name *Herba* or *Summitates hyperici,* and official in the French Codex. It is a native of Europe and Asia, introduced to the United States as a garden-flower, and now widely naturalized as a roadside weed. It is a smooth perennial herb, about 6 Dm. (2 Ft.) high and widely branching; leaves opposite, sessile, oblong or linear-oblong, nearly 2.5 Cm. (1 In.) long, obtuse, entire, strongly pellucid-punctate and somewhat black-dotted; flowers in cymes, terminating the branches, bright-yellow, 1.5 to 2.5 Cm. (½ to 1 In.) broad, the 5 acute sepals shorter than the strongly black-dotted petals; stamens coherent in 3 bunches; pistil tricarpillary, with 3 styles; fruit about a fourth of an inch long, ovoid, glandular, bearing the persistent styles. The drug contains a small amount of volatile oil, considerable tannin, and much resin, part of the latter, amounting to about 8 per cent. of the drug, a coloring-matter known as *hypericum-red,* soluble in alcohol, ether, and volatile oils, dissolving with a green color in alkalies, and yielding yellow precipitates with calcium and lead salts and a yellowish-green precipitate with ferric chloride. It is believed to be a mixture of two coloring-principles, one red and the other yellow, and to be mostly contained in the black glands. St. John's wort is said to possess properties analogous to the turpentines. It was formerly employed locally as a stimulating, desiccating, and cleansing application, and was employed internally as an emmenagogue, diuretic, and stimulating expectorant. The recent drug may be bruised and employed as a discutient for the relief of local pains, contusions, ulcers, and burns. It may be given internally in the treatment of chronic catarrhal conditions of the

respiratory, intestinal, and urinary apparatuses. Red oil or oleum hyperici, made by macerating 4 ounces of the tops in 1 pint of olive or linseed oil, is employed quite largely among the laity as an embrocation.

The genus *Hypericum*, L., contains upward of 200 species, and many of them appear to have similar constituents and properties. *H. connatum* Lam. (*Brathys c.* Spach.), the *Orelha de gato* of Brazil, is used as an astringent, as is also *H. laxiusculum* St. Hil., the *Alecrin bravo* of the same region. In southern Europe, *H. Androsæmum* L. (*Androsæmum officinale* All.) is used as an antispasmodic under the names *Mannsblut* and *Konradskraut*. *Sarothra gentianoides* L. (*S. hypericoides* Nutt.; *Hypericum Sarothra* Mx.; *H. nudicaule* Walt.), of North America, is a much-used laxative, alterative, and vulnerary, under the names *Pineweed*, *False St. John's wort*, *Orange grass*, and *Nit-weed*. The closely related tropical American genus *Caopia*, Adans. (*Vismia*, Vell.), consists of about 25 species of soft shrubs or small trees, and yields a number of native remedies of considerable importance, mostly anthelmintics. The coloring-matter of *C. acuminata* (*Vismia a.* Pers.; *V. caporosa* Kunth) acts as a drastic. The Chinese drug *Kiu-sze-ts'au*, used as an astringent and alterative, is *Cratoxylon polyanthum* Korth (*Hypericum Chinense* Retz.). The African *Ooina-gina* is *Haronga Madagascariensis* Chois. (*H. paniculata* Lodd.).

GYNOCARDIA.—Chaulmugra.

The ripe seed of *Hydnocarpus Kurzii* (King) Warb. (*Taraktogenos K.*—King.—Fam. *Flacourtiaceæ*), and perhaps also of *Gynocardia odorata* R. Br. (*Chaulmoogra o.* Roxb.; *Hydnocarpus o.* Lindl.; *Chilmoria dodecandra* Ham.—Fam. *Flacourtiaceæ*).

The recent statement of Power and Gornall that chaulmugra oil is derived from the first-named species must be viewed in the light of statements to the contrary by all preceding writers, as well as of their own statements, that the oil from that species, examined by them, does not agree in character with that examined by preceding analysts. It must, therefore, be regarded as at least possible that the commercial oil is from more than one source.

Origin and Description.—The seeds are produced by large trees. The first-named is a native of Burmah, the second ranging farther to the southeastward. The seeds of the first-named are numerous in a 6- (or 3-)celled, large, spherical, slightly pulpy fruit. Those of the second are contained in a 4- or 5-celled fruit. The seeds are about 2.5 Cm. (1 In.) long and half as broad, irregularly angularly ovoid, without ridges at the base. dull gray or yellowish gray, finely tomentose, the kernel shrunken away from the somewhat brittle testa, which is frequently seen broken. The kernel consists of a brown (white at first), oily albumen containing the embedded large embryo, which has a pair of leafy cordate cotyledons upon a thick caulicle. The odor of the crushed kernel is peculiar, faint, and rather disagreeable, as is the taste.

Constituents.—The authors quoted obtained by expression 30.9 per cent. of chaulmugra oil, a fatty oil of a specific gravity of 0.951 at 25° C. and 0.940 at 45° C., melting at 22.33° C., having an acid value of 23.9, a saponification value of 213, and an iodine value of 103.2. It yielded phytosterol ($C_{26}H_{43}OH$), and several fatty acids of the series $C_nH_{2n-4}O_2$, now first reported from a fatty oil. They confirm the statement of Deprez that the seeds yield hydrocyanic acid. They regard the "gynocardic acid" of previous authors as a mixture, and find *chaulmoogric acid*, which combines with only two atomic proportions of bromine or iodine. Hirschsohn obtained 40 per cent. of oil with a melting-point of 26° to 28° C., the constants varying considerably with the method of extraction, cold pressure, pressure with heat, and petroleum ether extraction being employed. Schindelmeiser found the melting-point to be 26° C. Other authors have reported the melting-point as high as 40° C. Dymock states that if 20 m. of the expressed oil be stirred with 1 m. of sulphuric acid, a reddish-brown resin-like mass is formed around the acid, which is not true of an oil obtained by boiling the seeds.

Deprez states that the seeds yield considerable hydrocyanic acid.

Action and Uses.—Gynocardia is rarely employed in medicine in this country, but in England the oil is extensively used in veterinary practice in the treatment of abrasions, wounds, sprains, etc. Chaulmugra oil is highly esteemed in India as a remedy for the treatment of leprosy, syphilitic, and other chronic lesions of the skin. It may be tried also for itch, pediculosis, and other parasitic skin diseases. The remedy has been given internally and applied externally in the treatment of muscular rheumatism and chronic diseases of the respiratory tract, and is said to be especially valuable in phthisis. The beginning dose of the oil to an adult is from 2 to 6 minims (0.10–0.40

Cc.), which may be increased to 15 minims (1 Cc.), 3 times daily. Gynocardic acid has been employed as a substitute, and may be given in doses of 1 to 2 grains (0.06–0.12 Gm.).

Allied Species.—The seed of *Hydnocarpus anthelmintica* Pierre, of China, is sometimes called False Chaulmugra or Chinese Chaulmugra, and has occurred in market under the name Chalugra. It is the *Ta-fung-tsze* of the Chinese, who employ it for the same purposes as Chaulmugra is used for. It is about half as long as Chaulmugra, relatively broader, has a thicker and harder testa, and bears some slight ridges radiating from the base. This seed, it is said, yields no hydrocyanic acid. The seeds of *Hydnocarpus venenata* Gærtn., of western India, and *H. Wightiana* Blume, of Ceylon, yield a similar oil, similarly used.

H.

HÆMATOXYLON, *U. S.*—Logwood.

Hæmatoxyli lignum, Br.; *Lignum Campechianum, Lignum cæruleum.—Blauholz, Blutholz, Campecheholz*, G.; *Bois de Campeche, Bois d' Inde, Bois de sang*, Fr.; *Palo de Campeche*, Sp.; *Pao de Campeche*, Port.

The heart-wood of *Hæmatoxylon Campechianum* L. (Fam. *Leguminosæ*).

Logwood is official in nearly all pharmacopœias. The Br. P. requires that the chips and coarse powder shall not be fermented, while several describe the greenish metallic color which indicates such fermentation. Such logwood has undergone chemical change, which is almost certainly deleterious to its quality.

Origin.—The logwood tree is a native of various parts of Central America, and has become naturalized, through cultivation and escape, in many parts of the West Indies. It is also introduced to cultivation in the East Indies. It has an irregular, knotty, hard, and tough trunk, crooked and straggling branches, alternate, pinnate leaves with 4 pairs of obcordate leaflets, loose racemes of yellow flowers, and thin, oblong, 2-seeded legumes. The tree is felled after reaching an age of about 10 years, and, after removal of the sap-wood, is cut into sections from 3 to 6 feet long, in which form it is exported. For dyers' use, it is cut into small chips or splinters, soaked with water, and exposed to light and air, being kept wet and occasionally turned over. By this process the chips become dark-colored, with a bluish-black or greenish-black metallic superficial stain.

Description.—Heavy, hard, and marked with irregular, concentric circles, splitting irregularly; vessels large, distinct to the naked eye; medullary rays very fine. Under the microscope the cell-walls are seen to have a red color, and the ducts and wood-fibers to be filled with a red resin-like mass, occasionally forming in the ducts crystals of a green metallic luster; odor faint, agreeable; taste sweetish, astringent. When chewed, it colors the saliva a dark-pink.

Logwood is generally met with in the form of small chips or coarse powder, of a dark brownish-red color. When a large part of the surface exhibits a greenish-black metallic luster, it has undergone fermentation, and should be rejected.

Constituents.—Logwood contains a little volatile oil, much brown extractive containing tannin, fatty or resinous and glutinous matter, and about 12 per cent. of the crystalline substance *hæmatoxylin*. This can be obtained from powdered logwood extract by mixing it with much sand and exhausting with ether; the ether is mostly recovered by distillation, and the residue mixed with water and crystallized, a little sulphurous acid or solution of a sulphite being added to prevent oxidation. When pure, hæmatoxylin is $C_{16}H_{14}O_6$, and crystallizes with 1 or 3 molecules of water in colorless or pale-yellow prisms which have a strongly sweet taste of liquorice; acquire a red color on exposure to the light, are freely soluble in hot water, in alcohol, and ether, and, fused with potassa, yield pyrogallol. The aqueous solution is slightly precipitated by solution of isinglass, and produces with baryta solution, lead acetate, and with copper salts white or grayish precipitates which rapidly turn blue. Ammonia dissolves hæmatoxylin, the solution being rose-red, then purple, and finally blackish-red; the fixed alkalies produce similar solutions, and the color ultimately becomes yellowish-brown. The blackish ammonia solution contains *hæmatein-ammonia*, from which acetic acid separates *hæmatein*, $C_{16}H_{12}O_6$; this is soluble in alcohol and hot water, slightly so in ether, and forms a blackish-violet crystalline powder having a green metallic luster, seen on the surface of chips which have been fermented. Hæmatein-ammonia causes, in a warm solution of a small amount of alum and with ferric chloride, deep-violet precipitates; with lead acetate, a brown one.

Pharmaceutical Preparation.—Extract of Hematoxylon, U. S. P.

Action and Uses.—Hæmatoxylon is mildly astringent and tonic, and well adapted to the treatment of serous diarrhœa. It is especially useful in infantile diarrhœa because of its agreeable taste. It has also been recommended in dysentery, and is said to be beneficial in the treatment of leucorrhœa. It may be applied externally to gangrenous and ill-conditioned ulcers.

The extract is given in the dose of from 10 to 30 grains (0.6–2 Gm.); and an unofficial fluidextract may be employed in doses of from ½ to 2 drachms (2–8 Cc.).

Allied Woods.—*Brazil wood*, used for dyeing and coloring purposes, very largely as a chemical reagent, and to a very slight extent in medicine, is derived from several species of *Cæsalpinia*, a genus rather closely related to *Hæmatoxylon*, of Brazil and other parts of tropical America. The genuine Brazil wood, *Lignum Fernambuci* or *Pernambuci*, is from *C. echinata* Lam., the tree known in Brazil as *Pao Brāzil* or *Ibiraperanga*. Its bark is rich in tannin and is used as an astringent. The wood is originally of a yellowish color, but on exposure becomes of a purplish-red. It possesses a somewhat sweetish and astringent taste. It is imported in billets, but as found in retail commerce is mostly in shavings. Its coloring constituent is *brasilin* ($C_{16}H_{14}O_5$), which is somewhat soluble in water, colorless when first extracted, but quickly reddened by sunlight, which changes it to *brasilein* ($C_{16}H_{12}O_5$). It dissolves in alcohol and ether with a yellowish color. Alkalies change it to a bright-red. Another variety, apparently containing the same substance, is imported from Bahia, and is known as *Bahia Brazil wood*. A closely related wood is *Brasilietto*, *Nicaragua* or *Saint Martha's wood*, derived from *C. Brasiliensis* Swz., of Jamaica and other parts of the West Indies. The wood of *C. Crista* L., of the same region, is practically identical with the last, and *Sappan* or *Samfen wood*, from the Indian species *C. Sappan* L., is very similar. *C. tinctoria* Domb. (*Coulteria t.* DC.), *Coulteria Chilensis* DC. (*Cæsalpinia tinctoria* H. et B.), and some other members of the genus, also yield dyestuffs.

HAMAMELIDIS CORTEX, *U. S.*—Hamamelis Bark.

Witch-hazel, Spotted hazel, Winter-bloom, Snapping hazel, E.; *Hamamelis, Zauberhasel*, G.; *Hamamelis*, Fr.

The bark and twigs of *Hamamelis Virginiana* L. (Fam. *Hamamelidaceæ*).

Origin.—The witch-hazel is a crooked or straggling large shrub, or occasionally a small tree, abundant in damp woods and thickets, especially in rocky soil, throughout eastern and central North America. The trunk, purplish brown and smooth when young, brown gray and sparingly fissured when old, is very apt to bear conspicuous whitish blotches of lichen-growth. During late fall and early winter the branchlets are thickly covered with the small bright-yellow flowers, at once recognized by their 4 linear petals. At the same time there may be numbers of the persistent fruits of the preceding season. The 2 black, shining seeds are oily and somewhat edible.

Description.—Hamamelis bark occurs in quills or quilled strips of variable length and width, the bark being about 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ In.) thick. The outer surface varies from purplish brown, with or without whitish patches, to entirely silvery white, and from smooth with a few warts to lightly fissured and scaly, or ragged, from separation of the thin cork. The inner surface is more or less long straight-striate, and is commonly of a pinkish cinnamon color, occasionally smoother and with a yellow tinge. Care should be taken to exclude that with the whitish wood adhering to the inner surface. The fracture is weak but fibrous.

FIG. 211.

Hamamelis bark (Nat.).

This bark has a weak odor and an astringent and bitterish taste. The transverse section exhibits a whitish band of stone-cells just outside of the bast-layer. The twigs are flexible and tough, of irregular length, not more than 6 Mm. ($\frac{1}{4}$ In.) in diameter, branching or bearing nodes at intervals of 2 to 5 Cm. (1 to 2 In.); externally varying from yellowish brown to deep purplish brown, lightly longitudinally wrinkled, and having scattered small circular whitish or pale lenticels; bark occupying about one-fifth of the radius; wood greenish white, lightly radiate, and exhibiting one to three annual rings; pith centric, small.

Twigs having a larger diameter than that described contain an undue percentage of inert wood, and will not agree with the description as to relative thickness of the bark.

Constituents.—Witch-hazel bark yields a slight amount of volatile oil, oleic, palmitic, and stearic esters of phytosterin ($C_{29}H_{44}O$), two tannins, and some gallic acid. Of the tannins, one is a glucoside, but the most important is *hamameli-tannin* ($C_{14}H_{14}O_9 \cdot 5H_2O$), which is entirely converted to gallic acid by hydrolysis.

Pharmaceutical Preparation.—HAMAMELIS WATER, U. S. P.

Properties and Uses.—The properties of witch-hazel bark are practically identical with those of the leaves (see HAMAMELIDIS FOLIA). While a fluidextract of it is often used, the official preparation is made from the leaves. The chief use of the bark, and especially of the twigs, is for the preparation of the distilled extract.

HAMAMELIDIS FOLIA, *U. S., Br.*—Hamamelis Leaves.

The dried leaves of *Hamamelis Virginiana* L. (Fam. *Hamamelidaceæ*), collected in autumn.

Hamamelis leaves are official in several other pharmacopœias.

The origin of witch-hazel leaves has been stated under HAMAMELIDIS CORTEX.

FIG. 212.

Lower surface of hamamelis leaf (½ Nat.): *a*, flower (× 2); *b*, fruit (Nat.).

Description.—Stoutly and very shortly petioled, the blade 7 to 15 Cm. (3–6 In.) long and nearly as broad or occasionally even broader, highly inequilateral, oval, with a very oblique, slightly cordate base, and usually a very short obtusish point at the summit, the margin coarsely sinuate; thickish, dull green, and with obscure venation above, paler or brownish green, with a satiny lustre and very prominent principal veins underneath, nearly smooth, the few hairs of the lower surface having much thickened walls and a very small lumen; odor rather faint, characteristic; taste astringent, slightly aromatic, bitter.

Leaves which have been collected earlier in the season than the definition requires have the lumen of the epidermal hairs correspondingly larger, with the walls thinner.

Constituents.—Much effort has been expended to discover a constituent of witch-hazel leaves to which could be referred their unquestionable clinical effects, but with little success. The small percentages of tannin and of bitter constituent appear not different from those of many other leaves which have no such properties. The volatile oil, in view of its important use in perfumery, considered in connection with its minute amount, should be worthy of careful investigation.

Pharmaceutical Preparations.—FLUIDEXTRACT OF HAMAMELIS, U. S. P.; SOLUTION OF HAMAMELIS, Br.

Action and Uses.—Witch-hazel owes its virtue largely to the tannic acid it contains. The fluidextract is frequently employed as an astringent gargle in subacute sore throat. Given internally it has enjoyed, perhaps, an undeserved reputation as a hemostatic in uterine oozing, hemoptysis, and hematuria, although it may be used with some success to check hemorrhage from the stomach, and, if injected into the bladder, may arrest bleeding from the wall of the latter viscus.

Recommended at one time as a drug to be given internally in venous engorgement of different parts of the body, its use in this condition has practically been abandoned.

The extract in suppository, or ointment, is largely employed in the treatment of bleeding piles with varying success. Hamamelis water, popularly known as extract of witch-hazel, enjoys a greater reputation in household medicine than perhaps any other drug.

The good that it exerts in the treatment of sprains, bruises, wounds, chilblains, sore eyes, headache, and a host of other conditions, resides more in the activity of a cleansing and evaporating lotion and in the mind of the user than in any decided curative properties that the preparation may possess.

The dose of the fluidextract is from 5 to 40 minims (0.30–2.60 Cc.); of the aqua hamamelidis, from ½ to 1 drachm (2–4 Cc.).

HEDEOMA, *U. S.*—Hedeoma.

American or Mock pennyroyal, Squawmint, Mosquito-plant, E.; *Amerikanischer Polei,* G.; *Pouliot americain,* Fr.

The dried leaves and tops of *Hedeoma pulegioides* (L.) Pers. (*Mentha p.* L.; *Cunila p.* L.; *Ziziphora p.* Desf.—Fam. *Labiatæ*).

Hedeoma is not elsewhere official, being the equivalent, medicinally, of the true Pennyroyal of the old world (*Mentha pulegium* L.).

Origin and Description.—Hedeoma is a low annual, growing in open and pref-

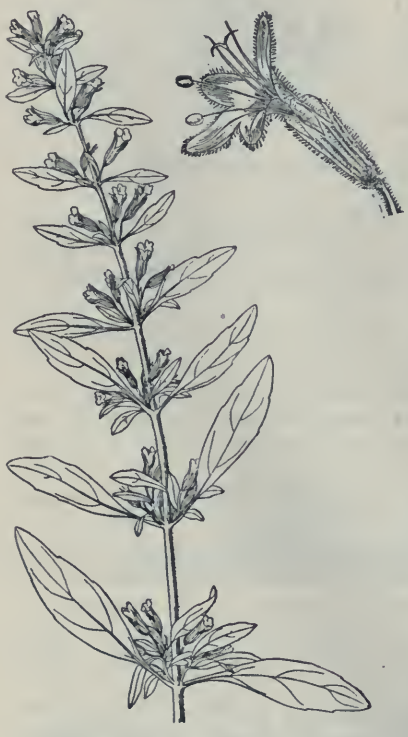
erably in dry and sterile situations throughout North America, except the far north and far west, and especially in the eastern central region.

Hairy throughout, the branches 4-angled, the leaves opposite, slenderly petioled; blades usually less than 2.5 Cm. (1 In.) long and 1 Cm. (⅔ In.) broad, oblong-ovate, narrowed gradually into the petiole, obtuse, distantly and shallowly serrate, pale- or grayish-green, thin, with few, strongly ascending secondary veins, and the lower surfaces beset with small, circular, depressed glands, which are usually golden-yellow and shining under a strong lens; flowers several in a leaf-axil, pedicelled, the calyx-tube cylindraceous, somewhat contracted at the mouth, strongly nerved, its tube 2-lipped and slenderly and sharply 5-toothed; corolla tubular, 2-lipped, pale-blue, spotted; stamens 4, 2 of them sterile; odor strong, somewhat mint-like; taste aromatic and pungent; nutlets 0.5 to 0.75 Mm. long, minutely papillose, oval or slightly obovoid, the summit rounded.

Constituents.—The only active constituent of Hedeoma is about 1 per cent. of volatile oil (see OLEUM HEDEOMÆ), with which there are a little tannin and a very small amount of a bitter principle.

Action and Uses.—Pennyroyal is a stimulant aromatic, which may be employed in the treatment of gastritis and colic attended with flatulence. It is occasionally combined with purgatives to prevent the griping effect which often attends their administration. A hot infusion, 1 ounce (30 Gm.) to 1 pint (480 Cc.), in conjunction with hot hip-baths and foot-baths, is frequently employed by the laity for the purpose of establishing retarded menstruation. The infusion may be given in doses of from 2 to 4 fluid-ounces (60–120 Cc.), every hour or two. It is very valuable for repelling mosquitoes by its odor.

FIG. 213.



a, Hedeoma (Nat.); *b*, flower (magnified).

Allied Drugs.—The genus Hedeoma contains about 15 species, all American, mostly of North America, all more or less aromatic, but none exactly like the official. *H. piperita* Benth., of Mexico, smells like peppermint, and is there used as a substitute for it. *H. thymoides* Gray, of Texas, etc., smells like Citronella, and is used as a stimulating aromatic. *Mentha Pulegium* L. (*s. Pulegium vulgare* Mill.) is the European pennyroyal (*Menthe pouliot, Pouliot commun*, Fr.; *Polei*, G.; *Poleo*, Sp.). It grows in moist sandy localities in central and southern Europe, has oval-obtuse and crenately serrate leaves, many-flowered axillary cymes forming globular whorls, and a purplish-colored 4-lobed corolla. It resembles the former in odor, while the taste is somewhat bitter and acrid.

One or more species of the related genus *Bystropogon*, large herbs or soft shrubs, and a *Micromeria*, all of the Andes, have an identical odor and could probably become cheap sources of supply for the oil of pennyroyal, since they could be mowed down in bulk.

HELLEBORUS.—Black Hellebore.

Radix hellebori nigri, Radix melampodii.—Christmas or New Year's rose, E.; *Schwarze Nieswurzel, Weinachtswurzel, Winterrose*, G.; *Hellebore noir*, Fr. Cod.; *Eleboro negro*, Sp.

The dried rhizome and roots of *Helleborus niger* L. (*H. grandiflorus* Salisb.—Fam. *Ranunculaceæ*).

Helleborus is official in many pharmacopœias.

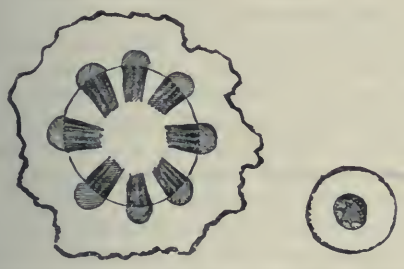
Origin.—The Christmas Rose is a low perennial herb of southern Europe, acclimatized also farther north, and often found in gardens in the United States. It derives its popular name from its habit of precocious spring-blooming, this occurring from December to March. It has long-petioled, radical, thickish, smooth, palmately 5- to 7-lobed leaves, red-mottled flower-stems, and large greenish-white or pinkish solitary flowers.

Description.—Grayish black and of an irregularly knotty appearance from the numerous short, stumpy branches, crooked, 2.5 to 7.5 Cm. (1 to 3 In.) long, 6 to 12 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ In.) thick, the branches annulate with the leaf-sheaths and terminating in single stem-scars, which are convex at first, becoming concave with age; roots numerous, brittle, originally long but mostly reduced by breakage to short stumps, about 2.5 Mm. ($\frac{1}{10}$ In.) thick, longitudinally wrinkled; transverse section of rhizome exhibiting a brownish-gray bark occupying about one-third of the radius, a zone of somewhat greater breadth consisting of 6 to 10 wedge-shaped bundles separated by broad medullary rays and a whitish pith; that of the roots showing a small slightly pentagonal or hexagonal wood in the center of a very thick bark; odor slight, taste sweetish, then bitterish and acrid.

Black Hellebore somewhat resembles Cimicifuga and has been mixed with it. The quadrangular roots of Cimicifuga, with their 4-lobed wood is characteristic, and it shows tannin reaction, which Hellebore does not. Hellebore has been adulterated with Actæa rhizome, which is thicker, shorter, with coarse roots, and more like Cimicifuga. Adonis is said to have been intermixed, but it bears no resemblance. Asphodel root has more than once been reported, but it has fusiform-thickened roots and a monocotyledonous structure. (For GREEN HELLEBORE, see *Allied Drugs.*)

Constituents.—Hellebore is free from tannin. Besides resin, gum, a little volatile oil, acrid fixed oil, a little wax, an acid (probably aconitic), bitter extractive, and gallates of calcium and potassium, it contains as its important constituents the 2 crystalline glucosides *helleborin* and *helleborein*. Helleborin ($C_{36}H_{42}O_6$) crystallizes from its aqueous solution, made by exhausting the concentrated tincture with hot water and filtering out the resin and fat. It is freely soluble in alcohol and chloroform, little so in ether and fixed oils, and scarcely in cold water. Its alcoholic solution has a burning taste. It yields sugar and helleboresin ($C_{30}H_{38}O_4$), which is in translucent crystals, slowly soluble in water, more so in alcohol and ether, bitter, and produces tingling of the tongue.

FIG. 214.



Helleborus niger L.: transverse section of rhizome and root.

FIG. 215.

Helleborus viridis L.: transverse section of rhizome.

Helleborein ($C_{26}H_{44}O_{15}$) can be obtained from the decoction by precipitating with basic lead acetate, then with sodium sulphate, and finally with tannin, decomposing this precipitate with lead oxide, exhausting the dry mass with alcohol, concentrating the tincture, and mixing with ether. It occurs in colorless nodules of minute crystals, readily soluble in water, less so in alcohol, insoluble in ether, and has a sweetish taste. It yields sugar and *helleboretin* ($C_{14}H_{20}O_3$), of a sweet and bitter taste, soluble in water, much less so in alcohol and ether, is precipitated by tannin, and crystallizes in rhomboidal crystals.

Action and Uses.—The internal administration of hellebore in moderate doses increases the force and decreases the rapidity of the heart's action. Arterial tension is increased partly because of the direct action of the drug upon the heart, and partly because of its stimulating effect upon the vagi. It augments the secretion of urine, and in full doses acts as a drastic hydragogue cathartic. Overdoses produce a violent gastro-enteritis with nausea, vomiting, and purging, and in pregnant women abortion sometimes occurs. If the dose is sufficiently large, headache, dizziness, muscular cramps, convulsions, and collapse ending in death may occur. Helleborein possesses local anæsthetic properties, and a solution containing $\frac{1}{160}$ grain (0.0004 Gm.) to each minim of water may be used in the eye as a substitute for cocaine. It does not dilate the pupil or increase intraocular tension. The drug cannot be employed hypodermically as an anæsthetic because of its powerful action upon the heart. Hellebore has been recommended in the treatment of acute mania and other forms of insanity, but is rarely employed at the present time for these conditions. Because of its drastic action it has been given for the

purpose of overcoming amenorrhœa and relieving ascites, but it is not a very desirable remedy in these states. The powdered drug has also been used to destroy vermin. As a drastic purge the dose is from 10 to 15 grains (0.60–1 Gm.); as an alterative, from 1 to 2 grains (0.06–0.12 Gm.).

Allied Drugs.—The rhizome and roots of *H. viridis* L., the *Green Hellebore*, etc. (not to be confused with American green hellebore or *Veratrum viride*), is regarded as more active than the Black, and is official in a number of pharmacopœias. It inhabits the same region and is naturalized in a few places in this country. Its green flowers are produced in spring. The rhizome is about half as large as the other and is knotty only at the summit, annulate with leaf-scars. Its transverse section exhibits 4 broad wood-bundles composed of a number of smaller ones, that of the roots a very small 4-lobed ligneous cord in the center. Its odor and taste are like those of the other, as is its composition, *helleborein* being the predominant constituent, as *helleborin* is of the black.

The rhizome of *H. fœtidus* L., the *Stinking hellebore*, *Bear's-foot*, *Garget-root* or *Setter-wort*, of Europe, is similarly used.

HEROINÆ HYDROCHLORIDUM.—Heroine Hydrochloride.

Chlorhydrate d'heroine, Fr.; *Salzsaures Heroin*, G.

Formula, $C_{17}H_{17}(C_2H_3O_2)_2NOHCl$. Molecular weight, 402.62.

The hydrochloride of diacetyl-morphine, an artificial alkaloid.

Preparation.—Heroine or diacetyl-morphine is obtained by heating pure morphine alkaloid with acetyl chloride, washing the product with water, then with dilute solution of sodium carbonate, and finally purifying by crystallization from hot alcohol. By dissolving the crystals in dilute hydrochloric acid, concentrating the solution, and setting aside to crystallize, heroine hydrochloride is obtained.

Properties.—Heroine hydrochloride is a white crystalline powder, soluble in 2 parts of water and soluble in alcohol, but insoluble in ether. An aqueous solution of the salt is readily precipitated upon addition of alkali hydroxide solutions, the base heroine, $C_{17}H_{17}(C_2H_3O_2)_2NO$, occurring as a white, odorless powder with alkaline reaction and having a bitter taste. Heroine melts at 173° C. (343.4° F.) and leaves no residue upon incineration. It is almost insoluble in water and ether, difficultly soluble in cold but readily soluble in hot alcohol, also soluble in chloroform and benzene. Solution of iodine causes a distinct turbidity in a solution of 1 part of heroine in 100,000 parts of water. The color-reactions produced by heroine are mostly similar to those of morphine. Unlike morphine, however, it does not liberate iodine from iodic acid, and produces a blue coloration with potassium ferricyanide and ferric chloride only after some time. With nitric acid it produces a yellow color, turning to red on warming. With concentrated sulphuric acid containing formaldehyde (2 drops of formaldehyde solution to 3 Cc. of acid) it produces a reddish-violet color changing to blue-violet. With Lloyd's test (1 part of hydrastine to 8 parts of the alkaloid to be tested, stirred into concentrated sulphuric acid) it produces a violet to purple coloration (J. L. Mayer). The alkaloid shaken with cold water gives a filtrate which decolorizes potassium permanganate solution, but gives no coloration with ferric chloride.

Action and Uses.—Heroine hydrochloride acts as a cough-sedative and respiratory stimulant, and has been proposed as a substitute for morphine for the relief of pain. When given in small doses, it has apparently no effect upon any of the vital functions except the respiration, which becomes deeper and slower. Large doses may cause dryness of the throat, dizziness, nausea, vomiting, depression, and, occasionally, constipation. Poisonous amounts, in addition to the above symptoms, produce twitching of the extremities, great exhaustion, and dimness of vision. The temperature becomes subnormal and the pulse rapid and thready. These symptoms should be treated by the application of heat, hypodermic injections of full doses of caffeine, and the administration of hot coffee by the stomach. Heroine has been employed in the treatment of acute and chronic bronchitis, emphysema, asthma, whooping-cough, the cough of phthisis, and uræmic dyspnœa. It has been proposed as a cure for the morphine-habit, and has been recommended as a substitute for opium in the treatment of diabetes mellitus. Heroine has also been recommended in the form of a suppository for the relief of pelvic pain. It is usually given in doses of from $\frac{1}{24}$ to $\frac{1}{12}$ grain (0.0025–0.005 Gm.), 3 or 4 times daily; but as much as $\frac{1}{6}$ grain (0.01 Gm.) may be employed.

HEXAMETHYLENAMINA, *U. S.*—Hexamethylenamine.

Hexamethylene tetramine, Urotropine, Uritone, Formin, Aminoform.

Formula, $C_6H_{12}N_4$ or $(CH_2)_6N_4$. Molecular weight, 139.18.

A condensation-product obtained by the action of ammonia upon formaldehyde.

Preparation.—The base hexamethylenamine may be obtained by adding to 100 parts of a 40 per cent. solution of formaldehyde, kept well cooled, gradually and in successive small quantities about 70 parts of stronger water of ammonia until an excess of ammonia is indicated by the odor after the solution has stood several hours. Then 10 parts of ammonia-water are added and the solution set aside for about 12 hours, after which it is poured into shallow dishes to crystallize. The crystals may be further purified by treatment with animal charcoal and subsequent recrystallization.

Properties.—Hexamethylenamine forms colorless, odorless, lustrous crystals of rhombohedral shape and having a sweetish taste. It dissolves at 25° C. (77° F.) in about 1.5 parts of water and at 100° C. (212° F.) in the same quantity of water. It is also soluble in 10 parts of alcohol at 25° C. (77° F.), and in about 8 parts of hot alcohol; soluble in 228 parts of ether.—U. S. The aqueous solution reacts alkaline with litmus. When heated to 230° C. (446° F.) in vacuo, hexamethylenamine sublimes almost without decomposition or previous melting. An aqueous solution (1 in 10), heated with diluted sulphuric acid is decomposed with liberation of formaldehyde (recognized by its odor or by its darkening paper moistened with silver ammonium nitrate test-solution), and if then supersaturated with sodium hydroxide solution, liberates ammonia. Tannic acid and mercuric chloride precipitate a 10 per cent. aqueous solution, the latter giving rise to a precipitate changing into colorless crystalline needles. —U. S. A bright-red color is produced on heating hexamethylenamine with concentrated sulphuric acid.

Action and Uses.—Hexamethylenamine, under the trade names Urotropine and Uritone, is employed as an antiseptic to the intestinal and genito-urinary tracts. When given internally it is rapidly absorbed and eliminated by the kidneys as an educt of urotropine which possesses acid and antiseptic properties. Urine loaded with pus, urates, and phosphates is rendered clear and acid in reaction by its administration. The remedy has been employed as a prophylactic, prior to operations upon the urinary tract, and is valuable in the treatment of pyelitis and phosphaturia. It is also largely used in the treatment of all stages of gonorrhœa, and is especially valuable when involvement of the posterior urethra occurs. It has been recommended in the treatment of typhoid fever as an intestinal antiseptic and for the purpose of rendering the urine free from the *Bacillus typhosus*. For the latter purpose it is very useful. Its continued administration may cause irritability of the bladder, and if the dose be excessive, hæmaturia may result. The ordinary dose is from 3 to 10 grains (0.20–0.60 Gm.), either in capsules or dissolved in water, 2 or 3 times daily. When taken in capsules it should be washed down with a copious draught of water.

Derivative Products.—Hexamethylene-tetramine Salicylate. *Urotropine salicylate, Saliformin.* $[(CH_2)_6N_4].C_7H_6O_3$. Molecular weight, 276.19.—This salt is prepared by dissolving equal parts of hexamethylene-tetramine and salicylic acid in 3 parts of water, and evaporating the solution to dryness at a temperature below 60° C. (140° F.). A colorless crystalline powder having a sweetish astringent taste, and soluble in water, alcohol, and chloroform. Soluble without color in cold sulphuric acid. The solution turns crimson on heating. Cupric sulphate produces a deep-green coloration and ferric chloride a violet color in the aqueous solution. Bromine causes a bright-yellow precipitate.

Hexamethylene-tetramine Bromethylate. *Bromalin, Bromalium, Bromoformin, Bromethylformin.* $[(CH_2)_6N_4]C_2H_5Br$. Molecular weight, 247.36. This product is formed by the interaction of equal parts of ethyl bromide and hexamethylene-tetramine dissolved in alcohol, and evaporation of the solution. Colorless scales or needle-shaped crystals, quite tasteless, soluble in water and alcohol, melting at 200° C. (392° F.) with decomposition, and on incineration producing a very voluminous cinder. Addition of bromine water to the aqueous solution yields a yellow precipitate. Hydroxide solutions liberate ammonia upon heating the aqueous solution.

Hexamethylene-tetramine Tannin. *Tannopin, Tannon.* $[(CH_2)_6N_4].[C_{14}H_{10}O_9]_3$. Molecular weight, 1098.16.—Prepared by precipitating 13 parts of hexamethylene-tetramine dissolved in water with a freshly prepared solution of 87 parts of tannic acid. A light-brownish odorless, tasteless powder, insoluble in water, dilute acids, alcohol, chloroform, and ether. It is soluble in alkaline solutions.

Ferrostyptin. $(CH_2)_6N_4HCl.FeCl_3$. Molecular weight, 336.4.—A double salt obtained by pouring a mixture of solutions of hexamethylene-tetramine hydrochloride and ferric chloride into 5 times its volume of alcohol, whereby crystals of the new compound are precipitated, which are subsequently washed with alcohol and dried. Yellowish-brown crystals, soluble in water, but insoluble in alcohol and ether, and containing 43–46 per cent. of anhydrous ferric chloride. Acids liberate formaldehyde upon heating the aqueous solution.

Hexamethylene-tetramine Iodoform. *Iodoformin.* $(CH_2)_6N_4.CHI$.—A fine, almost white powder of faint odor, and insoluble in alcohol, ether, and chloroform. It is obtained by triturating a mixture of 1 part of hexamethylene-tetramine and 3 parts of iodoform with absolute alcohol until dry. Exposed to light, it turns yellow. Cold as well as hot water decomposes the powder, liberating iodoform.

HIPPOCASTANUM.—Horse Chestnut.

Rosskastanie, G.; *Maronnier or Chataignier d'Inde*, Fr.; *Castagno d'India*, It.; *Castaño de Indias*, Sp.

The bark and seed of *Æsculus Hippocastanum* L. (*Hippocastanum vulgare* Gærtn.—Fam. *Hippocastanaceæ*), a beautiful shade and ornamental tree, introduced to the United States and Europe from India. The bark of the younger branches is preferred, and is used under the names *Cortex Hippocastani* or *C. castaneæ equinæ*. It is thin, brown-gray, somewhat warty and marked with opposite leaf-scars, which have the lower rounded margin marked with 5 or 7 small warts. The inner surface is whitish and smooth, the fracture fibrous and rather tough, and showing a brownish internal color. The bark has a peculiar and rather disagreeable odor, and a bitter, somewhat acrid and astringent taste.

Constituents.—The tannin of horse chestnut bark colors ferric salts green. Besides some fat, chlorophyll, and other common compounds, the bark contains *æsculin* ($C_{15}H_{16}O_9$) and *fraxin* (*paviin*, $C_{16}H_{18}O_{10}$), both principles being inodorous, of a slightly bitter taste, and showing a blue fluorescence when dissolved in water, particularly in the presence of an alkali. Æsculin is obtained by precipitating the decoction with lead acetate, treating the filtrate with H_2S, evaporating and recrystallizing. It forms small white needles containing 1½ molecules of water, which are insoluble in ether and have a slight acid reaction upon litmus. On boiling with dilute acid it is split into glucose and *æsculetin*. Baryta solution produces a like decomposition, and then yields *glucinic*, *apoglucinic*, and *æsculetinic acids*. Æsculetin ($C_9H_6O_4.H_2O$) crystallizes in colorless needles, is with difficulty soluble in cold water and alcohol, the solutions coloring ferric salts dark-green, dissolves in alkalies with a golden-yellow color, and on boiling with potassium hydroxide is decomposed into oxalic, formic, and protocatechuic acids. Fraxin is obtained by precipitating the alcoholic tincture with an alcoholic solution of lead acetate, diffusing the precipitate in water, decomposing by hydrogen sulphide, evaporating over sulphuric acid to dryness, and removing the tannin by washing with ice-cold water. It dissolves yellow in alkalies, colors ferric chloride green and then produces a lemon-yellow precipitate.

The integuments of the seeds contain some æsculin and *quercitrin*, which are likewise present in the flowers, but the leaves contain yellow *queræscitrin*. The cotyledons contain, besides starch and gummy matter, 2 to 4 per cent. of fixed oil (*Oleum hippocastani*), which is greenish-brown or yellow, has a turnip-like odor, a somewhat bitter taste, and the specific gravity 0.927, and congeals near the freezing-point of water. *Argyræscin* and *aphrodæscin* are 2 amorphous acrid bodies discovered by Rochleder (1862), which are insoluble in ether, soluble in alcohol, and yield with water solutions foaming like soap solution; the latter is precipitated by baryta water, and boiled with alkalies yields *butyric* and amorphous *æscinic acids;* the former is a glucoside.

A patented process is now in operation for extracting the bitter principles and saponin-like substance from the ground seeds by means of alcohol, the remaining portion being then used as food. It is said to contain 8 per cent. of proteid, 7 per cent. of fat, 77 per cent. of nitrogen-free extract containing 14 per cent. of sugar. The same substance can be made to yield richly of alcohol.

Action and Uses.—A decoction of the bark, and the active principle æsculin, have been largely employed in the treatment of malarial fevers. The leaves in decoction or infusion are employed as a remedy for whooping-cough. The fixed oil obtained from the fruit is used in France as an embrocation in the treatment of muscular rheumatism. The drug is said to possess sternutatory and antifermentative powers, but it is

rarely employed for this purpose. It is given in doses of ½ ounce (16 Gm.), in decoction, during the 24 hours. Æsculin may be given in 15-grain (1 Gm.) doses.

Æsculus Pavia L., *or Red buckeye.*—B. C. Batchelor (1873) obtained from the testa of this poisonous seed tannin, 3 per cent. of resin, a tasteless crystalline principle, and coloring-matter. The cotyledons were found to contain 5 per cent. of greenish-brown fixed oil, 2.5 per cent. of cane-sugar and syrup, and a brownish, bitter and acrid glucoside different from argyræscin, and apparently poisonous.

HIRUDO, *Br.*—Leech.

Hirudines, P. A., P. G.—*Sangsue médicinale*, Fr. Cod.; *Blutegel*, G.; *Sanguisuga, Mignatta*, F. It.; *Sanguijuela*, Sp.

Sanguisuga medicinalis Savigny, and *Sanguisuga officinalis* Savigny.

Class *Vermes;* Ord. *Annulata;* Sub-ord. *Apoda;* Family *Hirudineæ.*

Description.—Leeches are invertebrate animals with an elongated, roundish, or somewhat flattened body, which has numerous transverse wrinkles, and is generally attenuate toward both ends; the posterior one always terminates by a broad and muscular disk, by means of which the animal fastens itself upon objects. The blood-sucking leeches have their anterior end or head likewise terminated by a narrower disk, in the center of which is placed the mouth containing 3 jaws, which are provided with 2 rows of numerous pointed teeth, and are mutually inclined at an acute angle, so as to make a triangular incision through the skin. Respiration is carried on through small apertures or *stigmata* arranged in 2 rows on the abdominal surface and found at every fifth ring. Leeches are hermaphrodites, but mutually impregnate each other. Several pairs of testicles are located in the fore and middle part of the body; the filiform penis is projected from an abdominal orifice about one-third distant from the head, and the female organs with 2 ovaries have their aperture or vagina 5 rings below the penis. The ova are deposited near the edge of the water, invested with a kind of jelly or mucus, which contracts into a capsular or cocoon-like body having a spongy appearance and containing about 10 or more eggs. Leeches are aquatic animals, and swim with a vertical undulating motion. For medicinal use their weight should be between 1 and 5 Gm. (15 and 75 grains). The two species named have a soft smooth body, 5 Cm. (2 In.) or more in length, and have the back of an olive-green color, with 6 rusty-red longitudinal stripes, which are sometimes spotted with black.

Sang. (Hirudo L.) medicinalis Savigny has the belly greenish-yellow, more or less spotted with black, occasionally to such an extent that the prevailing color is black. The animal is indigenous to central and northern Europe, and is known in commerce as the *speckled, Sweedish*, or *German leech.*

Sang. officinalis Savigny (Hirudo provincialis Carena). The belly is light olive-green, unspotted, but marked with a black stripe on each side; the dorsal stripes are somewhat variable in width. This leech is indigenous to the southern part of Europe, and is known in commerce as the *green* or *Hungarian leech.*

Several other species of *Sanguisuga* of southern Europe are occasionally employed, but are not an article of commerce. Leeches are generally kept in ponds by the wholesale dealer, and even cultivated in this manner. They are usually transported imbedded in moist turf.

The *American leech, Hirudo decora* Say, which draws less blood, is sometimes employed. Its back is of a dark-green color and marked with 1 row of orange-brown and 2 lateral rows of black spots; the belly is of a light orange-brown color spotted with black.

Preservation.—Leeches require some attention to keep them healthy and in good condition. They are kept in clean river-water in a glass jar covered with a linen cloth and put in a shady place which is free from ammoniacal and other noxious vapors. The temperature is best kept between about 10° and 20° C. (50° and 68° F.), sudden changes being carefully prevented. As soon as the water begins to get turbid or colored the leeches should be placed in clean water of the same temperature and the jar well cleaned from the slimy deposit, which is caused by the transparent epidermis being thrown off every 4 or 5 days. To facilitate this removal, some material is often put into the jar through which the leech may draw itself, and which, by retaining this slime, will tend to keep the water clean; charcoal, pebbles, clay free from lime, moss, and Irish moss have been recommended and found advantageous for the purpose, and apparatuses have been constructed in which leeches may be kept on a bed of material which permits of a fre-

quent renewal of the water without handling the leeches. If they are kept in moist earth, turf, or clay, this should be examined from time to time and dead animals removed. The water should be changed at least once a week, and oftener in warm weather. It will be observed that the conditions for the preservation of leeches are pure air, pure water, and a pretty uniform temperature. Leeches are subject to several diseases which may become epidemic, and which are recognized by an excessive separation of mucus, ulcerations, tumors, or a flaccid appearance of the body; those thus attacked should be at once removed from the healthy ones, and placed in a separate vessel in clean water upon a layer of washed charcoal.

Action and Uses.—The employment of leeches as a therapeutic measure has long been a recognized procedure. The local abstraction of blood from the capillaries with leeches produces a very excellent effect in the early stages of acute local inflammatory conditions. Their employment is less painful and frequently more beneficial than any other form of local depletion. They may be applied to areas which are too tender to permit of cupping, and to parts where cups cannot be applied. Because of the slight pain attending their application this form of local depletion is admirably adapted to nervous cases. Before applying a leech, the skin should be thoroughly cleansed with soap and warm water, and afterward with plain hot water. The leech is usually placed in a tube or small bottle; which is then applied with the head toward the affected part, and as soon as the leech bites, the tube is withdrawn. Should the leech not take hold, a little milk, or blood from the patient, should be smeared over the selected spot, after which little or no difficulty will be experienced. They continue to suck until they become gorged with blood, when they usually drop off, but their removal may be effected at any time by sprinkling them with salt. The wound made by a leech usually bleeds for some time after the removal of the animal, and in some cases it is quite difficult to control the hemorrhage. Should the bleeding continue, simple pressure of the wound between the finger and thumb will usually control it. If the area is too painful for the employment of pressure, the application of styptics or the use of the actual cautery may be resorted to. The amount of blood drawn varies, depending upon the size of the leech, the part to which the leech is applied, and the severity of the existing inflammation. The European leech will draw from ½ to 1 fluidounce of blood, and the smaller varieties from 1 to 1½ fluidrachms. Leeches may be emptied by stripping them between the thumb and fingers, but this is not advisable.

HOMATROPINÆ HYDROBROMIDUM, *U. S.*, *Br.*—Homatropine Hydrobromide.

Homatropinum Hydrobromicum, P. G.; *Bromhydrate d'Homatropine*, Fr. Cod.; *Homatropinhydrobromid, Bromwasserstoffsaures Homatropin, Bromwasserstoffsaures Oxytoluyltropein*, G.

Formula, $C_{16}H_{21}NO_3.HBr$. Molecular weight, 353.49.

The hydrobromide of an alkaloid prepared synthetically by passing hydrochloric acid gas through a mixture of tropine and mandelic acid. It should be kept in well-stoppered vials, protected from the light.—U. S.

Preparation.—The base homatropine or oxytoluyltropine is obtained by heating for several days a strong solution of tropine mandelate (or a mixture of tropine and mandelic acid) on a water-bath with dilute hydrochloric acid. It may be more rapidly prepared by passing a current of hydrochloric acid gas over a mixture of tropine and mandelic acid heated to 110°–120° C. (230°–248° F.). The resulting product contains homatropine hydrochloride and some undecomposed tropine mandelate. By addition of ammonia water the homatropine is precipitated, the tropine salt not being decomposed by ammonia, and may be shaken out with chloroform. After dehydrating the chloroformic solution with potassium carbonate, the base is obtained in the form of a dark-colored syrupy liquid by distilling off the solvent. The residue is taken up with dilute hydrobromic acid, and the salt allowed to crystallize and further purified by re-solution and crystallization from alcohol.

Properties.—Homatropine hydrobromide occurs as colorless to white, non-deliquescent, odorless, crystalline powder or minute rhombic prisms, soluble in 6 parts of cold water (Br.) (4 parts, Hager), in 5.7 parts of water at 25° C. (77° F.) (U. S.), in 1 part of boiling water, in 32.5 parts of alcohol (U. S., 18 parts, Hager), in 8.7 parts

of alcohol at 60° C. (140° F.), U. S., in 133 parts of absolute alcohol, but insoluble in ether and almost insoluble in chloroform (620 parts at 25° C. (77° F.), U. S. (note that the hydrobromides of atropine and hyoscyamine are readily soluble in chloroform). It melts at 213.8° C. (417° F.), U. S., 210°–212° C. (410°–413.6° F.) (Hager). Its solutions are neutral. In aqueous solutions not too dilute fixed alkali hydroxides cause a precipitate soluble in excess of the reagent. Silver nitrate produces a white precipitate, and in solutions acidulated with hydrochloric acid yellow precipitates are caused by gold chloride and phosphomolybdic acid, and a white precipitate by phosphotungstic acid. Tannic acid and platinum chloride cause no precipitate in the acidulated solution. Picric acid produces a yellow amorphous precipitate changing to crystalline scales. Solution of iodine causes a brown, and mercuric chloride a white precipitate. The solutions are strongly mydriatic, dilating the pupil of the eye.

Tests.—The salt should be soluble in cold concentrated sulphuric acid without color. It should leave no ash after ignition. The free alkaloid obtained by extraction with chloroform or ether from an aqueous solution made alkaline with sodium hydroxide, should have a melting-point of 95°–96° C. (203°–204.8° F.), U. S. (distinction from atropine and hyoscyamine, melting respectively at 115.5° C. and 108° C.). If about 0.01 Gm. be dissolved in a little water and the solution rendered alkaline with solution of ammonia and shaken with chloroform, the separated chloroform will leave on evaporation a residue which will turn yellow, and finally brick-red, when warmed with about 1.5 Cc. of a 2 per cent. solution of mercuric chloride in a mixture of 5 volumes of alcohol and 3 volumes of water (U. S., Br.) (absence of other alkaloids, except atropine and hyoscyamine). If 2 Cc. of chloroform be shaken with 1 Cc. of an aqueous solution of the salt (1 in 10), to which a few drops of chlorine water have been cautiously added, the chloroform should assume a brownish color. If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should not acquire a violet color upon the addition of a few drops of alcoholic potassium hydroxide test-solution (absence of atropine, hyoscyamine, or hyoscine), U. S. The Ph. G., in giving the last-named test, states that a transient violet color will appear, followed by a reddish-yellow color. Sulphuric acid containing a trace of potassium dichromate, when added to a crystal of the salt, produces a momentarily pink color, changing rapidly to green (U. S.).

The base homatropine is hygroscopic, but only slightly soluble in water, soluble in alcohol and chloroform, less readily in ether, optically inactive to polarized light, and melts at 98° C. (208.4° F.) (Hager).

Homatropine hydrochloride, sulphate, and salicylate, are colorless crystalline salts, readily soluble in water and alcohol.

Action and Uses.—When given internally, homatropine closely resembles atropine in physiological action, except that it slows the action of the heart and decreases blood-pressure. When a solution is instilled into the eye, it produces some hyperæmia of the conjunctiva, dilatation of the pupil, and paralysis of accommodation. Mydriasis usually begins in from 10 to 20 minutes; paralysis of accommodotion is complete in from 60 to 90 minutes; and complete recovery usually takes place in from 36 to 48 hours after the repeated instillation of a few drops of a solution containing 4 grains (0.25 Gm.) of the drug to 1 fluidounce (30 Cc.) of distilled water. Because of its transient effect, and the fact that it rarely produces systemic effects, it has been employed by ophthalmic surgeons for the purpose of correcting anomalies of refraction. It is inferior to atropine in the treatment of the various diseased conditions of the eye in which a lasting mydriasis is desired. The internal dose is stated to be from $\frac{1}{80}$ to $\frac{1}{20}$ grain (0.0008–0.003 Gm.).

HORDEUM DECORTICATUM.—Pearl Barley.

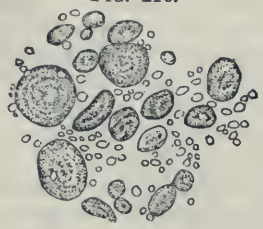
Hordeum perlatum.—Perlgerste, Perlgraupen, G.; *Orge perle,* Fr. Cod.; *Orzo perlado,* Fr., It.; *Cebada perla,* Sp.

The seeds of *Hordeum distichon* L. (Fam. *Gramineæ*), from which the integuments and outer portions of the kernel have been removed.

Origin.—The barley plant is an annual grass, indigenous probably in western Asia, now cultivated in all temperate regions. It presents a great number of cultivated forms,

some of them, distinguished respectively by the production of 2, 4, or 6 rows of seeds to the spike, being commonly regarded as distinct species. The official article may be obtained from any of these. When the outer integuments (pericarp) alone are removed, "Pot-barley" is produced. To obtain pearl barley, the seed so resulting is subjected to a farther partial grinding, by which the integuments and part of the kernel of the seed are removed, and the ends rounded off. Both the mill-stone and its case rotate vertically, in the same direction, the former about 20 times as rapidly as the latter.

Fig. 216.



Barley starch-granules.

Description.—From 2.5 to 4 Mm. ($\frac{1}{10}$ to $\frac{1}{8}$ In.) long, and from two-thirds to equally as broad, somewhat flattened, the broader sides oval to rotund, one of them marked by a longitudinal groove in which remains of the brownish integument are visible, the color elsewhere white. The smaller grains consist only of the central starchy portions; some of the larger bear a layer of gluten-tissue upon the surface. Barley is inodorous and has only an amylaceous and faintly sweetish taste. The starch-granules are mostly single and somewhat resemble those of wheat. The outline is somewhat irregularly elliptical to circular, and both the hilum and rings are indistinct. Their size averages about 26 mikrons.

Constituents.—Barley has the ordinary nutritive composition of the cereal grains. There are from 60 to 68 per cent. of starch, 12 to 16 per cent. of combined albumin and gluten, 2 to 3 per cent. each of fat and ash, 8 to 12 per cent. of cellulose, and 10 to 14 per cent. of moisture, with a little crystallizable sugar. The fat consists of glycerides of palmitic and lauric ("hordeic") acids. With these, are various enzymes, chiefly diastase. Sinistrin was reported by Kühnemann. Traces of tannin, an amaroid, and cholesterin have also been detected. Mills and Pettigrew have remarked that an aqueous solution of calcium carbonate or sulphate dissolves an increased amount of extractive, while the amount of albuminoids is thereby decreased.

Action and Uses.—Pearl barley is never employed medicinally in the solid state, but because of its non-irritating properties a decoction, made by adding 1 pint (480 Cc.) of cold water to 2 drachms (8 Gm.) of the drug, slowly boiling down to 12 fluid-ounces (360 Cc.) and straining, has long been given as a nutrient, diuretic, and demulcent in febrile complaints and in inflammatory states of the respiratory and urinary tracts. Unless a contraindication to the use of sugar exists, the decoction may be sweetened and flavored with lemon juice to suit the taste.

HUMULUS, *U. S.*—Hops.

Lupulus, Br.; *Strobili humuli or lupuli.—Hop*, E.; *Houblon*, Fr. Cod.; *Hopfen*, G.; *Lupudo, Hombrecilles*, Sp.; *Lupulo, Luparo, Pe de Gallo*, Port.; *Luppulo*, It.

The carefully dried strobiles of *Humulus Lupulus* L. (*Lupulus communis* Gærtn.—Fam. *Moraceæ*), bearing their natural glandular indumentum.

Hops are official in nearly all pharmacopœias, some of which require that they be renewed annually, or reject those which smell of valerianic acid or those which have been bleached with sulphurous acid.

Origin.—From a high-climbing (twining) perennial, dicœcious herb, with rough stems and herbage, and mostly opposite, broadly ovate, cordate, mostly 3- to 5-lobed leaves. It is native of northern and central Asia and Europe, and apparently of North America also, being common in our northwestern region. It is one of the most important of cultivated crops, being grown in all cool countries, but doing poorly under a warm climate. It is trained to poles or upon trellises. Effort is made to avoid the presence of the male plants near the fields, in order to prevent the fertilization of the ovules, which causes deterioration of the hops. The latter develop in pendulous clusters. Aside from insect pests, they are subject to the attacks of a fungus, which is objectionable in the product. The hops are picked when fully grown, but before ripening, and are very carefully dried. Very much of the quality depends upon care in drying, which should not be either over- or under-done. Artificial drying, under shade, by hot air, yields the best results. Hops are either stored loose or pressed into bales or cakes. In storage they turn brown, and are almost certain to undergo chemical changes, resulting

in the development of a strong valerianic acid odor, and many methods have been tried to prevent this. One is to treat them with sulphurous acid fumes, but this is in itself objectionable. It is sometimes resorted to for restoring the color to browned hops. Another method is to sprinkle them with alcohol before pressing. This results in the development of special odors, but prevents that of valerianic acid. Various substances are occasionally added, but, of course, should not be present in medicinal hops. It is very desirable that hops should not be used after keeping for more than a year. Very commonly, a portion of the glandular powder (*lupulin*) is removed by abrasion, before marketing, which proportionately reduces their value.

Description.—Ovoid-cylindrical, about 3 Cm. (a little more than 1 In.) long, consisting of a thin, hairy, flexuous rachis and many obliquely ovate, blunt, membranaceous, rigid, glandular scales, which are parallel-veined below, reticulately veined above and each bearing a globoidal akene near the base; color of scales yellowish-green to greenish pale-brown, free from reddish or brown spots; odor strongly and peculiarly aromatic, taste bitter, pungently aromatic, slightly astringent.

The most important element of the powder is its lupulin. (See LUPULINUM.) The ash amounts to about 10 per cent.

Careful attention should be given to the presence of the normal amount of the glandular coating, and this can scarcely be estimated except by experience in physical examinations. Hops from which it has been removed are apt to be much broken, and this condition is then concealed by pressing into cakes or bales. Hence unbroken loose hops are indicative of good quality, though these do not keep so well. Hops which have been kept for more than a year are called "olds"; those kept more than two years are often termed "old-olds." Both have to be sold at a heavy discount.

Constituents.—Besides other principles contained in the glands (see LUPULINUM), hops contain 0.8 per cent. of greenish- or reddish-brown volatile oil, 9–18 per cent. of resin, wax (myricyl palmitate), 4 per cent. of lupulotannic acid, phlobaphene, choline or lupuline, trimethylamine, pectin, 1 per cent. of asparagin, diastase (?), a fermentable sugar, phosphates, nitrates, malates, citrates, etc. Brand (1892) found boric acid in the strobiles, leaves, stalks, and tendrils. The volatile oil, which is an article of commerce, is aromatic, not bitter, varies from light-yellow to brown, thickens somewhat with age, has a specific gravity of 0.855 to 0.890, and is little soluble in alcohol. It consists chiefly of *humulene*, a sesquiterpene. The other constituents are little known. The resinous portion is a mixture of 3 distinct resins, of which one is crystalline and unites with bases, and another, the alpha-resin, retards lactic fermentation but not acetic. The *lupulotannic* (humulotannic) acid is whitish, amorphous, soluble in alcohol, hot water, and acetic ether, but not in ether. The phlobaphene ($C_{50}H_{46}O_{25}$) is a decomposition-product from the tannin. It is dark-red, amorphous, and on boiling with dilute acids splits into glucose and hop-red.

Pharmaceutical Preparations.—ELIXIR OF HOPS, FLUIDEXTRACT OF HOPS, N. F.; TINCTURE OF HOPS, U. S. P.

Action and Uses.—Hops are tonic, diuretic, sedative, and somewhat anaphrodisiac. They have been recommended in the treatment of certain nervous conditions associated with, or depending upon, general debility. As antispasmodics they may be employed with benefit in the treatment of delirium tremens, hysteria, priapism, seminal emissions, and incontinence of urine depending upon an irritable bladder. In the form of a hop pillow a soporific effect may be exercised in the treatment of insomnia, but it is probable that the fumes of the alcohol used to moisten the hops are the more active agents in producing this effect. A hop poultice made by mixing the powdered strobiles with some emollient substance may be employed in the treatment of boils, bruises, other painful inflammations, and in muscular rheumatism. Of the infusion, ½ ounce (16 Gm.) to 1 pint (480 Cc.), from 1 to 2 fluidounces may be given at intervals of an hour or two. The tincture is usually prescribed in doses of from 1 to 3 fluidrachms (4–12 Cc.).

HYDRANGEA.—Hydrangea.

The dried root of *Hydrangea arborescens* L. (*H. vulgaris* Mx.—Fam. *Saxifragaceæ*). *Seven-barks.*

Hydrangea is not elsewhere official.

Origin and Description.—A soft and weak shrub, common and abundant on banks, especially near streams and in rocky soil, in the Ohio valley and southward. The grayish stem-bark exfoliates in successive thin layers, whence the name *Seven-barks.* The accompanying cut illustrates the habit of the plant. The flowers are small and greenish, but there is often a marginal circle of large, white, and neutral ones. The fruit is a 2-celled and 2-beaked, many-seeded capsule. The roughly branched roots are of a very pale-yellowish or brownish-white, and the thin bark readily scales off from the white, smooth, tough, and soft wood. The bark is sweetish, afterward slightly pungent, but the wood is nearly tasteless.

FIG. 217.

Hydrangea: root (Nat.).

Constituents.—Hydrangea contains, besides fat, resin, starch, a little volatile oil, etc., about 1 per cent. of the glucoside *hydrangin*, giving a bluish fluorescence in alkaline solutions, disappearing on the addition of acids, soluble in ether and alcohol, and crystallizing in stellate masses

FIG. 218.

Hydrangea: branch (½ Nat.).

(Bondurant). Schroeter gives it a melting-point of 228° C. (442° F.) and the formula $C_{34}H_{25}O_{11}$.

Action and Uses.—Seven-barks is said to be diuretic and narcotic, and in addition to possess the power of dissolving renal calculi, which is manifestly impossible. In over-

dose it occasions headache, vertigo, and respiratory embarrassment. The remedy is employed to a limited extent in the treatment of gravel, and is said to cause the expulsion of small stones from the kidney and bladder. It is best given in the form of a fluid extract, of which 1 fluidrachm (4 Cc.) may be administered.

The common garden *Hydrangea root* (*H. paniculata grandiflora*) contains, according to Luebert, 2.38 per cent. of sugars, 2.42 per cent. of mucilage, a trace of dextrin, 2.37 per cent. of pararabin, 9.46 per cent. of starch, 8.12 per cent. of ash, parahydrangin (a glucoside), wax, and caoutchouc.

HYDRARGYRI CHLORIDUM CORROSIVUM, *U. S.*—Corrosive Mercuric Chloride.

Hydrargyri perchloridum, Br.; *Hydrargyrum bichloratum*, P. G.; *Hydrargyrum muriaticum corrosivum, Hydrargyrum corrosivum sublimatum, Hydrargyri bichloridum, Sublimatus corrosivus, Sublimatum corrosivum, Mercurius sublimatus corrosivus.*—*Mercuric chloride, Perchloride of mercury, Corrosive sublimate, Bichloride of mercury*, E.; *Deutochlorure de mercure, Sublimé corrosif, Chlorure mercurique*, Fr.; *Quecksilberchlorid, Aetzender Quecksilbersublimat*, G.

Formula, $HgCl_2$. Molecular weight, 268.86.

It should contain not less than 99.5 per cent. of pure mercuric chloride, and be kept in well-stoppered bottles.—U. S.

Owing to the intensely poisonous properties of this salt, great care should be exercised on the part of the compounder and others, not to confound it with mild chloride of mercury (calomel), which has a similar composition. Such names as perchloride, bichloride, or chloride, for corrosive sublimate, and subchloride, for calomel, may lead to confusion and mistakes, especially in a case of haste.

Preparation.—The pharmacopœias give no specific directions for preparing the salt. It is manufactured by subliming in a suitable apparatus an intimate mixture of mercuric sulphate and sodium chloride in the proportion of 20 parts of the former to 16 of the latter. The change taking place is expressed thus: $HgSO_4 + 2NaCl = HgCl_2 + Na_2SO_4$. At the temperature of sublimation $HgSO_4$ is decomposed; the acid residue attacks the sodium chloride, forming stable sodium sulphate, while the two volatile residues Hg and Cl pass off and condense in the cooler part of the apparatus as mercuric chloride. The commercial salt almost always contains a small quantity of calomel, from which it is freed by dissolving the chloride in water, filtering off the insoluble calomel, and recrystallizing.

The salt may also be prepared by dissolving mercuric oxide in hydrochloric acid, or mercury in nitrohydrochloric acid, and crystallizing.

Properties.—Corrosive sublimate occurs in colorless rhombic prismatic crystals, or, more generally, in heavy white crystalline masses. When ground, it forms a heavy pure-white powder. It melts near 265° C. (509° F.) and boils near 295° C. (563° F.). It has the density 5.4, sublimes without residue when pure, is permanent in the air, inodorous, has a disagreeable acid metallic taste, and dissolves in about 2 parts of boiling water (U. S., Br.), 3 parts (P. G.), and 13 parts of water at 25° C. (77° F.); also in 3 parts of alcohol, in 4 parts of ether (Br.), 12 to 14 parts of ether (P. G.), freely soluble in volatile oils, in 1.2 parts of boiling alcohol, and about 14 parts (2 parts, Br.) of glycerin. In the presence of camphor the solubility is increased, so that 4 parts of ether and 16 parts of camphor will dissolve 8 parts of corrosive sublimate, and 4 parts of alcohol, with 25 parts of camphor, will dissolve 16.5 parts of corrosive sublimate (Karls, 1827; Simon, 1836). The aqueous solution has an acid reaction, becomes neutral on the addition of sodium chloride, and when exposed to the light is partly decomposed, with precipitation of calomel and liberation of hydrochloric acid; the decomposition is prevented by the presence of free hydrochloric acid or of ammonium chloride. The aqueous solution yields yellow precipitates of mercuric oxide with an excess of lime water (see LOTIO HYDRARGYRI FLAVA) or potassium hydroxide solution, a white precipitate of ammoniated mercury with ammonia, and on the addition of silver nitrate a white curdy precipitate of silver chloride, insoluble in nitric acid but soluble in ammonia. Phosphorous and sulphurous acids separate calomel from the solutions; hypophosphorous acid and stannous chloride produce the same change, but when in excess and heated liberate metallic mercury. The salt is soluble without decomposition in sulphuric, hydro-

chloric, or nitric acid, and crystallizes on cooling. Solutions of albumen or of tannin form insoluble combinations; also sugar, gum, fats, resins, decompose it slowly with precipitation of calomel, light and warmth hastening the action. It forms insoluble combinations with most of the alkaloids, which fact is often utilized to prepare pure alkaloids from such insoluble double salts.

Tests.—If 1 Gm. of the finely powdered salt be dissolved in 10 Cc. of alcohol or 20 Cc. of water, it should leave not more than 0.005 Gm. of residue. If a solution of 0.5 Gm. of the salt in 20 Cc. of water and 5 Cc. of hydrochloric acid be completely saturated with hydrogen sulphide, allowed to stand for several hours in a corked flask, and then filtered, the filtrate should be colorless and leave no weighable residue upon evaporation (absence of many foreign salts). The precipitate of sulphide thus obtained is thoroughly washed with water, drained, and then rinsed into a beaker with about 20 Cc. of water; this mixture is digested with 5 Cc. of stronger ammonia-water for about 15 minutes on a boiling water-bath in the covered beaker, filtered, and washed with a little water; the filtrate and washings, after evaporating to dryness, moistening with 6 drops of nitric acid and again drying, should not respond to the modified Gutzeit's test for arsenic (see under Arseni Trioxidum). If the residue remaining on the filter be treated with diluted nitric acid (1 in 4), warmed, and then filtered, the filtrate, upon evaporation and gentle ignition, should leave no weighable residue (limit of foreign metals).—U. S.

Preparations.—Corrosive Sublimate Catgut.—Thin catgut is soaked for 8 hours, thicker kinds from 10 to 12 hours, in a 5 per cent. aqueous solution, after which it is kept in bottles with alcohol.

Corrosive Sublimate Cotton.—According to a sanitary regulation for the German army, the antiseptic solution is prepared by mixing: corrosive sublimate, 50 Gm.; alcohol, 6500 Gm.; water, 7500 Gm.; glycerin, 1000 Gm.; fuchsin, 0.5 Gm.; the latter serving to distinguish the cotton from others. This solution is sufficient for 10–12 kilograms of cotton, which is soaked in it and dried in loose layers.

Corrosive Sublimate Gauze.—The above quantity of solution is sufficient for 400 meters of gauze, which is well kneaded and soaked in it for 15 minutes, then pressed, and hung up to dry in a place free from light and dust.

Corrosive Sublimate Silk.—Well-washed silk is soaked in a solution of 100 parts of water, 20 parts of glycerin, and 5 parts of corrosive sublimate, and after drying, wrapped in waterproof material. Before being used, it is dipped into a 3 per cent. phenol or a 1 per cent. sublimate solution.

Action and Uses.—Corrosive sublimate is used in medicine for three purposes: as a germicide or antiseptic, as an antisyphilitic, and in some diseases as a tonic. Its most important use is as a germicide and antiseptic. Even in so weak a solution as 1 to 20,000 it is capable of destroying micro-organisms, and in stronger solutions of destroying their spores. In the strength of about 1 to 1000 it is in many respects the most powerful and best germicide that we possess. The chief objections to its use as a germicide are that it is expensive, comparatively speaking, and that it is decomposed when it comes in contact with albuminous or other organic matter. Again, it is a very powerful poison when taken internally, and as its solution is perfectly clear, it is a dangerous drug for common employment, because it is so readily taken in error. When used as an antiseptic in surgery, it is commonly employed in a solution varying from 1 to 10,000 to 1 to 2000, and occasionally much stronger solutions than this are employed. The objections to its use as an antiseptic are, first, its irritant properties; second, the fact that it forms with the albumin of the tissues an insoluble albuminate of mercury; third, if used in strong solution it devitalizes the tissues, or even acts as a caustic; and fourth, it may be absorbed.

As an antisyphilitic the drug may be given in the dose of $\frac{1}{30}$ to $\frac{1}{20}$ grain (0.001–0.003 Gm.) several times a day. Usually when it is employed for combating syphilis it is administered by the hypodermic needle, about $\frac{1}{6}$ grain (0.01 Gm.) being injected into the fold of the buttock or into the broad muscles of the back where the tissues are lax, on every second or third day; the drug is slowly absorbed from the area into which it is primarily injected, being precipitated by the juices of the tissues immediately after its injection. This method of treatment is not entirely devoid of pain, and careful antiseptic precautions should be carried out lest the injury to the tissues combined with an infection may cause an abscess. Sometimes in cases of obstinate syphiloderm, $\frac{1}{2}$ ounce (16 Gm.) of corrosive

sublimate and 1 ounce (30 Gm.) of chloride of ammonium are added to a warm bath, the patient then being immersed in the water for 20 minutes or half an hour, and the bath repeated 2 or 3 times a week.

As a tonic, corrosive sublimate is given internally by many practitioners in the dose of $\frac{1}{100}$ grain (0.0006 Gm.) in cases of anæmia. At one time corrosive sublimate was employed internally in large doses, frequently repeated, in the treatment of diphtheria; but with new and more clear conceptions of this disease, and the introduction of antitoxin, this use of the drug has almost entirely ceased. It is also worthy of note that it is employed as an antiseptic by surgeons very much less frequently than it was some years ago, because asepsis, or perfect cleanliness, has been found adequate for the rapid healing of wounds and the disadvantages of an irritant antiseptic have been recognized. Dermatologists quite frequently employ solutions of bichloride of mercury for the purpose of destroying parasites of the skin, and for the purpose of removing chloasma and freckles.

When corrosive sublimate is taken in poisonous dose, it produces violent inflammation of the stomach and bowels with vomiting and purging, and this is speedily followed by irritation of the kidneys and partial or complete suppression of urine. The symptoms of poisoning are quite rapid in their onset, and are usually severe, there being active vomiting, and purging, with great pain in the abdomen. The treatment consists in the administration at the earliest possible moment of a large quantity of white of egg to form an insoluble albuminate of mercury; in the administration of sufficient opium to relieve the pain and to check the excess of vomiting; in the application of heat to maintain the body temperature; and, after the acute stage of poisoning is passed, the administration of a saline purge to sweep the insoluble albuminate of mercury from the alimentary canal. Sometimes corrosive sublimate has been absorbed from surgical dressings, and produced symptoms of mercurialization, such as ptyalism and renal irritation. Other instances have been reported in which the administration of a vaginal douche containing large quantities of this chloride has resulted in local inflammation with secondary irritation of the kidneys.

HYDRARGYRI CHLORIDUM MITE, *U. S.*—Mild Mercurous Chloride.

Hydrargyri subchloridum, Br.; *Hydrargyrum chloratum*, P. G.; *Hydrargyri chloridum, Hydrargyrum chloratum (muriaticum) dulce, Mercurius dulcis, Calomelas.—Calomel*, E., Fr., G.; *Mercurous chloride, Protochloride of mercury, Mild chloride of mercury*, E.; *Protochlorure (Sous-muriate) de mercure, Mercure doux*, Fr.; *Quecksilberchlorür*, G.

Formula, HgCl. Molecular weight, 233.68.

Keep in bottles impervious to light. It should contain not less than 99.5 per cent. of pure salt.—U. S.

Preparation.—Mild mercurous chloride is manufactured by subliming in a suitable vessel an intimate mixture of mercuric chloride and mercury in the ratio of 4 to 3, during which the following change takes place: $HgCl_2 + Hg = 2HgCl$. It is also made by grinding together mercuric sulphate and mercury in the ratio of 10 to 7 till the mercury is no longer visible, and then thoroughly mixing with 5 parts of sodium chloride and subliming by heating. The changes taking place are: $HgSO_4 + Hg = Hg_2SO_4$, mercurous sulphate being formed, which when heated with sodium chloride reacts in the same manner as described under Mercuric Chloride; thus, $Hg_2SO_4 + 2NaCl = 2HgCl + Na_2SO_4$, forming vapors of mercurous chloride. If these vapors are cooled and condensed in a small space, white or yellowish-white crystalline masses are obtained, which should be finely powdered. To avoid this operation, the condensation is directed to be effected in a large chamber, whereby a fine crystalline powder is obtained; it is condensed in a similar form, but still finer and as a still softer powder, by injecting steam into the condensing-chamber while the sublimation is in progress. Calomel prepared in this way is designated in the German Pharmacopœia as *Hydrargyrum chloratum vapore paratum*, and is known in France as *Calomel à la vapeur*. Water being at the same time condensed, it will hold any corrosive sublimate in solution which may have sublimed with the vapors of calomel. It is for the purpose of removing the same impurity that the ordinarily condensed calomel requires to be washed with water as long as mercuric

chloride is dissolved, which is indicated by the filtrate producing a white turbidity with ammonia or a black one with ammonium sulphide. A current of cold air injected into the condensing-chamber will precipitate the calomel vapors as a soft powder in a manner similar to that produced by steam.

Very finely divided calomel, *Hydrargyri chloridum mite præcipitatione paratum*, known in France as *Précipité blanc* (which should not be confounded with ammoniated mercury), is obtained by gradually adding a not too concentrated solution of mercurous nitrate to a solution containing an excess of sodium chloride, digesting the mixture for a short time, and washing the precipitate thoroughly with water. Wöhler (1854) proposed the reduction of corrosive sublimate in solution by sulphurous acid and by warming the mixture. Good results and nearly the theoretical quantity of calomel are obtained, according to Sartorius (1855), if the corrosive sublimate has been dissolved in 80 parts, or, according to Stein (1857), in 45 parts of water. Concentrated solutions yield only one-half the mercury as calomel.

Some pharmacopœias and also many text-books on chemistry employ the formula Hg_2Cl_2, instead of HgCl, for calomel. This case is similar to that presented by ferric chloride (see under FERRUM). It seems to have been definitely settled that HgCl is the correct molecular formula for calomel, as shown by vapor density determinations. H. Erdmann (*Lehrb. d. Anorg. Chem.*, 2d ed., 1900) says that the formula Hg_2Cl_2 has no foundation, and should be discarded.

Properties.—Calomel is a heavy, fine, smooth, and impalpable white powder, which under the microscope is observed to consist of minute needle-shaped crystals, but when prepared by levigating the crystallized mass it forms irregular fragments of crystals which in bulk have a yellow cast. These two varieties are usually met with in commerce. Calomel obtained by precipitation is in very minute particles, either crystalline or amorphous, but on account of its more energetic action is rarely used. The salt is without action on test-paper, is entirely inodorous and tasteless, and is not altered in the dark on exposure to the air; but if kept in the light, it gradually acquires a gray or blackish color, indicating decomposition. Its density is about 7, but varies somewhat as prepared by different processes. When heated, it sublimes completely without previous fusion. It is insoluble in water and other simple solvents, but boiled with water it is slowly decomposed into metallic mercury and mercuric chloride. Solutions of the fixed alkalies and alkaline earths decompose it, with the formation of black mercurous oxide, Hg_2O (see LOTIO HYDRARGYRI NIGRA); ammonia water also colors it black, but the resulting product is a mixture of Hg and $NH_2.HgCl$. When mixed with a dry caustic alkali, alkaline earth, or an alkali carbonate, and heated, decomposition takes place, metallic mercury being produced. Moist calomel is reduced to the metallic state by many metals either in the cold or on being warmed, soluble chlorides and metallic mercury being formed. Boiling nitric or sulphuric acid dissolves calomel, with disengagement of nitric oxide or sulphurous acid vapors and the production of mercuric chloride and nitrate or sulphate. Boiling concentrated hydrochloric acid converts it into mercuric chloride and mercury; in the diluted state, and heated in contact with the air, mercuric chloride is slowly formed without separation of mercury. Calomel left in contact with solution of ammonium chloride is gradually converted into mercuric chloride, which dissolves; the decomposition occurs more rapidly with a concentrated solution and a somewhat elevated temperature. Potassium and sodium chlorides have a similar effect, but react more slowly. According to Jolly's observations (1878), corrosive sublimate is also formed from calomel in the presence of hydrochloric acid, citric acid, alkalies and their carbonates, and alkaline earths, but not with calcium carbonate nor with sugar that is absolutely free from lime. Chlorine water converts calomel into corrosive sublimate. With potassium iodide a green powder is produced containing mercurous iodide. When triturated with impure sugar some corrosive sublimate is formed.

Tests.—Calomel should volatilize without residue when heated (absence of fixed impurities). The filtrate obtained after shaking 1 Gm. of the salt with 10 Cc. of water or alcohol should not be colored or rendered turbid upon acidifying with hydrochloric acid and mixing with an equal volume of hydrogen sulphide solution after standing corked for at least half an hour at 35° C. (95° F.), either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals); nor should it leave any appreciable residue upon evaporation (absence of soluble impurities). If the filtrate obtained after

shaking 1 Gm. of the salt with 10 Cc. of ether be evaporated and 5 Cc. of distilled water be added, no opalescence should result upon adding silver nitrate test-solution (absence of mercuric chloride). When a portion of the salt is heated with potassium hydroxide test-solution ammonia should not be evolved; and when another portion is shaken with acetic acid and filtered, the filtrate should not be affected by hydrogen sulphide solution nor by silver nitrate solution (distinction from and absence of ammoniated mercury). If 0.5 Gm. of the salt and 5 Cc. of nitric acid be evaporated to dryness on a water-bath, the residue, when dissolved in 25 Cc. of water and 5 Cc. of hydrochloric acid and treated further as described under HYDRARGYRI CHLORIDUM CORROSIVUM, should show the absence of foreign salts, arsenic, and foreign metals.

Action and Uses.—The action of calomel upon the human body is very closely allied to that of metallic mercury; although if very large doses of it are given, it is likely to prove slightly more irritating to the gastro-intestinal mucous membrane. Indeed, very large doses are prone to produce vomiting and purging for this reason. The question as to the manner in which calomel is absorbed into the system is still *sub judice*, and is shrouded with so much doubt that it is scarcely worth while in this place to enter into a prolonged discussion as to the various theories which have been advanced concerning this point. Calomel undoubtedly is the most powerful of all the preparations of mercury in producing bilious stools, but here again very different opinions exist among pharmacologists and physicians as to the exact manner in which it produces this effect, some persons claiming that part of the calomel is changed into the bichloride of mercury; others that it is altered into the gray oxide before it exercises its cholagogue influence. Then, too, it is by no means as yet decided as to whether calomel actually increases the secretion of bile by the liver, or whether it simply increases the flow of bile from the gall-bladder. So far as we know, there are no experiments which prove the correctness of either of these views. Indeed, the only experiments which can be considered of value are certain investigations made upon the lower animals and man, which seem to prove that calomel does not increase the flow of bile at all, and are in direct antagonism to the clinical experience of the entire medical profession in active practice. While the experiments upon human beings have not been very numerous, all of them are in accord that the administration of calomel does not increase the flow of bile from a biliary fistula. On the other hand, every practitioner knows that the administration of an adequate dose of calomel not only produces a movement of the bowels, but a very great increase in the quantity of bile contained in the stools. Indeed, after one or two active calomel movements the following stool may consist almost entirely of bile. So far as we know, there is no explanation of this conflict between experimental and practical observation.

Calomel is used in medicine chiefly in cases of biliousness or torpidity of the liver as a stimulant to the flow of bile and as an intestinal antiseptic. It is indicated chiefly when the tongue is foul and the stools are light and putty colored, and is particularly valuable in those cases in which these symptoms complicate malarial fever, when quinine often fails to act against the infection until calomel is freely used. For the purpose of affecting the liver, the dose varies from 1 grain (0.06 Gm.) in divided doses, to 20 grains (1.3 Gm.) in divided doses, according to the severity of the malady and the degree of hepatic torpor. Sodium bicarbonate and ipecac are often given with it to increase its efficacy. Calomel is also used in small doses to check excessive vomiting complicating biliousness, and in cases of gastro-intestinal catarrh to relieve congestion of the gastric mucous membrane by unloading an engorged liver. It is also useful in the early stages of the infectious fevers to stimulate the liver.

Calomel should not be used in the treatment of jaundice unless there is reason to believe that the bile-ducts are patulous, since its administration when the ducts are closed probably increases the jaundice in that the bile which ordinarily would escape into the intestine under its influence is dammed up and so absorbed in large quantity.

In many cases of dysentery calomel is a useful remedy, acting more largely probably by the flow of bile which it produces and by the decreased hepatic congestion which results from its use than by any direct effect upon the intestinal wall.

Calomel is used as a dusting-powder for the removal of syphilitic condylomata, and in certain diseases of the skin in this form or in ointment. Placed on a plate over a water-bath it is sublimed and the vapors used by direct application to syphilitic skin lesions, or the sublimed fumes are inhaled for the cure of mucous patches in the mouth.

This measure may also be used to mercurialize the general system through its absorption by the lungs and skin. For inhalation, it is sufficient to sublime 1 to 2 grains (0.06–0.12 Gm.) a day. When a general skin effect is desired, as much as 20 grains (1.3 Gm.) are to be used, the patient being made to sweat during the process. In other instances, calomel is given hypodermically in the treatment of syphilis, being injected into the deep muscular tissue, as in the buttock, suspended in water by means of mucilage of gum arabic. From these injections slow absorption of the mercurial takes place, and, unless the greatest possible precautions are taken, great pain and abscess may follow. The method is not looked upon with much favor, since other preparations of mercury, such as the bichloride, lend themselves to this plan of treatment more readily. When used internally in the treatment of syphilis, it is common to combine it with opium to prevent it from being eliminated too rapidly by purgation.

Some years ago the profession had a very strong belief that mercury, chiefly in the form of calomel, exercised an antiphlogistic influence, diminished the coagulability of the blood, and also decreased active inflammatory processes in serous membranes in particular. As a consequence it was largely employed in pericarditis, pleurisy, meningitis, and peritonitis; but this use of the drug has now become almost entirely obsolete. In certain conditions of renal disease with dropsy, and also in dropsy depending upon cardiac disease with congestion of the liver, calomel not only acts as a purgative, but also as an efficient diuretic, and forms one of the ingredients of the celebrated pill which is composed of a grain of calomel, a grain of squill, and a grain of digitalis leaves.

The use of sublimated calomel by inhalations also has a high reputation with some physicians in the treatment of diphtheria.

After the internal use of full doses of calomel for its hepatic effect a saline purge should be given some hours later to sweep the drug from the body lest it cause general systemic effects by its absorption.

The best way in which to administer calomel is in tablet triturates, not compressed, or in powders.

HYDRARGYRI CYANIDUM.—Mercuric Cyanide.

Hydrargyrum cyanatum, P. G.; *Hydrargyrum borussicum*, *Mercurius cyanatus s. borussicus.*—*Mercuric cyanide*, *Cyanuret of mercury*, E.; *Cyanure (Bicyanure, Prussiate) de mercure*, Fr.; *Cyanquecksilber*, *Quecksilbercyanid*, G.

Formula, $Hg(CN)_2$. Molecular weight, 250.18.

Mercuric cyanide should be kept in well-stoppered bottles, protected from light.

Preparation.—It may be prepared by dissolving mercuric oxide in hydrocyanic acid, keeping the latter in slight excess to prevent the formation of an oxycyanide, $HgO.Hg(CN)_2$. The solution is concentrated, and set aside in a cool and dark place to crystallize.

Another method is to rub together 4 parts of Berlin Blue with 3 parts of yellow mercuric oxide and 20 parts of water, and heat the mixture 1 to 2 hours on a water-bath, replacing the water that evaporates from the dish. The mixture is then heated to boiling until the blue color disappears. If after 10 minutes' boiling the blue color remains, more mercuric oxide must be added. The liquid is filtered, the residue washed with hot water, the combined filtrates acidified with hydrocyanic acid, evaporated, and set aside to crystallize. The reaction taking place is: $Fe_4[Fe(CN)_6]_3 + 9HgO = 9Hg(CN)_2 + 3FeO + 2Fe_2O_3$.

Properties.—Mercuric cyanide is in colorless or white quadrangular prisms, which are inodorous, have a bitter, metallic taste, and are permanent in the air if light be excluded. The salt is soluble at 15° C. (59° F.) in 12.8 parts of water (P. G.) and in 12 parts of alcohol, also in 3 parts of boiling water and 6 parts of boiling alcohol, but is very sparingly soluble in ether. The solutions have a neutral reaction to test-paper. The aqueous solution is not decomposed by nitric or dilute sulphuric acid, but hydrochloric acid liberates hydrocyanic acid, recognizable by its odor, and mercuric chloride remains in solution; it yields a black precipitate with hydrogen sulphide, but does not give the ordinary reactions for mercuric salt or cyanide when tested with alkalies, potassium iodide, or silver nitrate, double compounds, mostly crys-

talline, being formed, which are more or less freely soluble in water. The salt is blackened by exposure to the light, and when carefully dried and heated is decomposed into mercury and cyanogen, which is inflammable, burning with a purplish flame; but when rapidly and strongly heated the crystals decrepitate violently, and black paracyanogen is first produced before the whole is finally dissipated, and in the presence of moisture carbon dioxide, ammonia, and hydrocyanic acid are evolved. When mixed with an equal weight of iodine, and heated in a dry test-tube, two crystalline sublimates are obtained, the lower one consisting of mercuric iodide, being yellow and becoming red on cooling, while the upper one, consisting of cyanogen iodide, CN.I, is white and has a penetrating, acrid odor. It is the only easily soluble cyanide of the heavy metals.

Tests.—Mercuric cyanide dissolved in water should not impart a brown color to turmeric paper (absence of mercuric oxycyanide). A 5 per cent. aqueous solution of the salt, when mixed with a dilute aqueous solution of potassium iodide, should not yield a red or reddish precipitate soluble in excess of the precipitant (absence of mercuric chloride). In the presence of a *little* chloride this test is apt to fail unless the potassium iodide solution be very cautiously added. A much better test is the following: The solution of the salt in 20 parts of water slightly acidulated with nitric acid, should not produce a white precipitate on the addition of test-solution of silver nitrate. The absence of salts of other metals is shown by the complete volatility by heat. Solution of mercuric cyanide does not give a stain of mercury on bright copper except in presence of hydrochloric acid.

Action and Uses.—Cyanide of mercury possesses the alterative powers of mercury and the depressant powers of hydrocyanic acid, and as it has no antisyphilitic value over safer and better tried mercurials it should be discarded. Not only is its influence depressing, but it is an irritant salt of mercury. Used in syphilis it may be given in the dose of $\frac{1}{12}$ grain (0.005 Gm.), 3 times a day. It has also been used hypodermically in the treatment of this disease in about half this dose.

Hydrargyri et Zinci Cyanidum, *Hydrargyro-zincum cyanatum.—Mercuric and zinc cyanide*, E.; *Lister's double salt; Quecksilberzinkcyanid*, G.; *Cyanure de mercure et de zinc*, Fr.—This preparation was proposed by Sir Joseph Lister in 1889 as an antiseptic non-irritating dressing. It is obtained by mixing a solution of 28 parts of zinc sulphate with a solution of 25 parts of mercuric cyanide and 130 parts of potassium cyanide, washing, and drying the precipitate. Lister thought the substance was a definite chemical compound, $Hg(CN)_2.Zn(CN)_2$, but it is found that the mercury varies from 15 to 46 per cent. according to conditions. It is used to impregnate gauze, on which it is fixed by mordanting the gauze in solution of aniline dyes, as gentian-violet and methyl-violet 1 in 50,000. Of late, hæmatoxylin has also been used as a mordant instead of the aniline dyes.

Hydrargyri Oxycyanidum, *Hydrargyrum oxycyanatum, Mercuric oxycyanide*, E.; *Quecksilberoxycyanid, Mercurioxycyanid*, G. $Hg(CN)_2.HgO$.—This is obtained by dissolving precipitated mercuric oxide in a solution of an equivalent amount of mercuric cyanide, heated on a water-bath, filtering through asbestos, and evaporating to crystallization. It forms a fine white crystalline powder with a tinge of yellow, soluble in 17 parts of water. The solution is precipitated by tannic acid and stannous chloride; with ammonia, the precipitate formed is soluble in excess of the reagent; hydrogen sulphide throws down black mercuric sulphide.

HYDRARGYRI IODIDUM FLAVUM, *U. S.*—Yellow Mercurous Iodide.

Hydrargyri Iodidum Viride, U. S. 1880.—*Hydrargyrum iodatum flavum, Hydrargyri proto-ioduretum.—Protoiodide of mercury, Yellow (or Green) iodide of mercury*, E.; *Protoiodure de mercure, Iodure mercureux*, Fr.; *Quecksilberjodür, Gelbes Iodquecksilber*, G.

Formula HgI. Molecular weight, 324.40.

It should contain not less than 99.5 per cent. of pure salt.—U. S.

Preparation.—Mercury, 50 Gm.; nitric acid, potassium iodide, distilled water, each a sufficient quantity. Mix 20 Cc. each of nitric acid and distilled water, and, when the liquid is cold, pour it upon the mercury contained in a small glass flask. Set the mixture aside in a cool and dark place, and agitate it occasionally until the reaction ceases and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate which will have formed from the mother-liquid, allow them to drain in a glass funnel, and dry them on bibulous paper in a dark place. When the salt is dry, weigh off 40 Gm. of it, and dissolve it in 650 Cc. of distilled water to which 6 Cc. of nitric acid had

previously been added. Having prepared a solution of 16 Gm. of potassium iodide in 32 Cc. of distilled water, slowly pour the solution of potassium iodide into that of the mercurous nitrate, with constant stirring; stir the mixture for 15 minutes, allow the precipitate to subside, decant the supernatant liquid, and wash the precipitate by decantation with ten successive portions of 500 Cc. each of distilled water. Finally, transfer the precipitate to a filter, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 40° C. (104° F.). Keep it in dark, amber-colored vials, and expose it to light as little as possible. Instead of weighing off 40 Gm. of the mercurous nitrate as above directed, the whole of the crystallized salt may be taken and the amount of potassium, etc., adjusted on the proportion given above.—U. S.

When solutions of a mercurous salt and potassium iodide are brought together, mutual decomposition results and mercurous iodide is formed, together with a salt of the alkali, as shown by the following reaction: $2HgNO_3 + 2KI = 2(HgI)$ or $Hg_2I_2 + 2KNO_3$.

The object of adding the potassium iodide to the mercurous nitrate in the official process is to avoid the formation of mercuric salt, which is apt to occur if the process were reversed; it is well known that solutions of alkali iodides and also ferrous iodide will decompose mercurous iodide into mercuric iodide and mercury, the mercuric salt being held in solution as the double potassium mercuric iodide, while the mercury is precipitated in a finely divided state. The decomposition is readily understood from the equation: $2HgI + 2KI = HgI_2 2KI + Hg$. Dilute solutions also insure a pure product, and the presence of nitric acid prevents the formation of basic salts.

The former U. S., Br., and German pharmacopœias all directed the preparation of mercurous iodide by triturating iodine and mercury together in proper proportions in the presence of a little alcohol; any mercuric iodide formed was removed by washing with alcohol. The Br. P. and P. G. dismissed this compound entirely in 1885 and 1890 respectively. When prepared by direct union, mercurous iodide is much more green in color, and this is also the case if appreciable quantities of mercuric iodide are present, as may be seen from the change of color caused by exposure of the yellow iodide to sunlight, which causes decomposition into mercuric iodide and metallic mercury, the bluish color of the latter, with the yellow iodide, giving a green effect.

Properties.—Mercurous iodide (official) is a bright-yellow amorphous powder, odorless and tasteless, and becoming darker by exposure to light in proportion as it undergoes decomposition into mercuric iodide and mercury. It is wholly insoluble in alcohol or ether, and almost insoluble in water. When slowly heated, it assumes at first an orange, and then a red or red-brown color, becoming yellow again on cooling; but when quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is completely volatilized. Mercurous iodide dissolves in ammonia water, leaving a gray residue, and in sodium thiosulphate solution, leaving mercury, and yielding a colorless liquid, which on heating deposits dark-red mercuric sulphide. When it is heated with sulphuric acid and a little manganese dioxide, vapors of iodine are evolved.

Tests.—If 0.5 Gm. of the salt be shaken with 10 Cc. of alcohol, and filtered, a portion of the filtrate should scarcely be affected by hydrogen sulphide test-solution, nor should it produce more than a very faint, transient opalescence when dropped into water; and if 5 Cc. of the filtrate be evaporated from a white porcelain surface, not more than a very faint red stain should remain (absence of more than traces of mercuric iodide).—U. S. Fixed impurities, if present, remain behind if a portion is heated to redness in a porcelain crucible.

Action and Uses.—This preparation is almost universally regarded as the best of all the mercurials for the treatment of secondary syphilis in that it combines the alterative influence of mercury and iodine, and is readily eliminated from the system. The best method of using it is to give the patient tablet triturates of ¼ grain (0.015 Gm.) each, and have him take 1 tablet 3 times a day after meals on the first day, and on the second day to increase the evening dose by 1 tablet; on the third day to take 1 tablet in the morning, 2 at noon, and 2 at night; and on the fourth day 2 tablets 3 times a day; increasing the dose day by day in this manner till symptoms of mild mercurialism develop, such as tenderness of the gums or diarrhœa, when the dose is cut down one-half and maintained at that level. This is the so-called "tonic dose."

If taken in overdose for a considerable period of time, the protiodide rapidly produces severe ptyalism, but it is not so prone to do so as is calomel. Single large poisonous doses cause gastro-enteritis and diarrhœa with vomiting. The antidote is starch and white of egg.

HYDRARGYRI IODIDUM RUBRUM, *U. S., Br.*—Red Mercuric Iodide.

Hydrargyrum bijodatum, P. G.; *Hydrargyrum iodatum rubrum.—Biniodide of mercury, Deutoiodide of mercury, Mercuric iodide*, E.; *Deuto-iodure (Bi-iodure) de mercure, Iodure mercurique*, Fr.; *Rothes Jodquecksilber, Quecksilberjodid*, G.

Formula HgI_2. Molecular weight, 450.30.

It should contain not less than 99.5 per cent. of pure salt.—U. S.

Preparation.—Corrosive mercuric chloride, 40 Gm.; potassium iodide, 50 Gm.; distilled water, a sufficient quantity. Dissolve the corrosive mercuric chloride and the potassium iodide each in 800 Cc. of distilled water, and filter the solutions separately. Pour both solutions simultaneously and in a thin stream, with constant stirring, into 2000 Cc. of distilled water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold distilled water until the washings give not more than a slight opalescence with silver nitrate test-solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stoppered bottles, protected from light.—U. S.

The Br. P. (1898) has dropped the process of preparing this salt, simply stating that it is formed by interaction between potassium iodide and mercuric chloride.

Mercuric chloride and potassium iodide, when mixed in the proportion of the weight of 1 molecule of the former to 2 of the latter salt, decompose each other into mercuric iodide, which precipitates, and potassium chloride, which remains in solution: $HgCl_2 + 2KI$ yields $HgI_2 + 2KCl$. The U. S. P. uses the two salts in the proportion of 4 to 5, which is a slight excess of the potassium salt over the theoretical quantity, but is generally necessary in practice, owing to the small percentage of impurities always present in commercial potassium iodide. By calculation it is found that 4 parts of mercuric chloride require for complete decomposition 4.898 parts of potassium iodide, or 9 parts of the former require 11.02 parts of the latter salt. By mixing the two solutions cold the red iodide is separated in the form of powder, but when the hot solutions are mixed and slowly cooled beautiful crystals are obtained. In either case the yield should be about 60 per cent. more than the weight of the corrosive sublimate used.

Properties.—Mercuric iodide is a scarlet-red amorphous or crystalline powder or is in brilliant crystals. It is permanent in the air if kept in the dark or in diffused daylight, but acquires a brownish tint in the sunlight. It is inodorous and nearly tasteless, a metallic taste being slowly developed when kept upon the tongue. On being heated to above 150° C. (302° F.), it turns yellow, but on cooling readily resumes its red color under various influences. It fuses at 253° C. (487.4° F.) to an amber-colored liquid, and at a higher heat sublimes to bright-yellow tabular crystals which after cooling are again converted into the prismatic or octahedral red crystals. The salt is very sparingly soluble in cold or hot water, little so in ether and diluted nitric acid, but more freely soluble in hydriodic or hydrochloric acid, in potassium iodide or chloride, in many ammonium salts, in solutions of mercuric salts, in chloroform, fixed oils, hot carbon disulphide, etc. It dissolves in 116 parts of alcohol, 85 parts of ether, and 1340 parts of chloroform at 25° C. (77° F.), and in 15 parts of boiling alcohol (U. S.), crystallizing on cooling; on pouring the alcoholic solution into cold water the salt separates as a fine yellow powder, remaining suspended in the liquid and gradually turning red. The solutions are colorless, and are partly decomposed by potassium hydroxide solution, a portion of the mercury being deposited as a mixture of $HgI_2.3HgO$ and HgO, the remainder forming a soluble iodide of potassium and mercury. On heating the salt with solution of soda and glucose or sugar of milk, metallic mercury will be precipitated, and on heating it with sulphuric acid and black manganese oxide, vapors of iodine will be given off. When a hot solution of potassium iodide is saturated with mercuric iodide and then allowed to cool, one-third of the latter salt crystallizes out; the remainder is obtained, on further concentration, as yellow prisms, which are soluble in alcohol and ether, but are partly decomposed by water. The crystals are *mercuric potas-*

sium iodide, $(2KI.HgI_2)3H_2O$, more generally known as *potassium iodohydrargyrate*, and are likewise formed on adding mercuric chloride to an excess of potassium iodide.

Tests.—Impurities, if present, are readily detected by the residue left on subliming the salt (red oxide of lead and other non-volatile compounds) and on dissolving it in hot alcohol (vermilion, etc.). The cold alcoholic solution should be colorless and without acid reaction (mercuric chloride), and on the addition of ammonia should acquire merely a brown color, but not be precipitated (mercuric chloride). If about 0.5 Gm. of the salt be shaken with 10 Cc. of water, the filtered liquid should not become more than very slightly colored by hydrogen sulphide test-solution, nor afford more than a slight opalescence with silver nitrate test-solution (limit of *soluble chlorides* or *iodides*). —U. S.

Pharmaceutical Uses.—The observation of Nessler (1856) of the effect of ammonia upon solutions of mercuric iodide has resulted in the discovery of a very delicate reagent for minute quantities of ammonium salts, known as the

Nessler Reagent.—It is made by dissolving 50 Gm. of potassium iodide in a little boiling distilled water, and adding to it, carefully, sufficient boiling hot concentrated solution of mercuric chloride until the red precipitate formed is no longer redissolved on agitation; the liquid is decanted and filtered, and the filtrate mixed with 200 Gm. of potassa dissolved in a small quantity of water; when cold the mixture is diluted to the measure of 1 liter by the addition of distilled water. The addition of 5 Cc. of cold saturated solution of corrosive sublimate is recommended by some, but is not necessary. It will be observed that this is a solution of mercuric potassium iodide in caustic potassa. On the addition of ammonium salt this is decomposed by the potassa, ammonia is liberated, and reacts now with the double iodide and another portion of the potassa, resulting in the formation of brown insoluble dimercur-ammonium iodide, potassium iodide, and water, as will be seen from the equation: $NH_3 + 2(HgI_2.2KI) + 3KOH = NHg_2I + 7KI + 3H_2O$. If the ammonia is present in minute quantity, the color is observed best by looking through the column of the liquid contained in a tall test-tube and placed on white paper.

Winckler (1830), von Planta (1846), and Groves (1858) observed the behavior of solutions of the double iodide upon solutions of vegetable alkaloids, which led F. F. Mayer (1862) to the adoption of one-tenth normal solution, now known as

Mayer's Solution.—It is prepared by dissolving 13.546 Gm. of mercuric chloride and 49.8 of potassium iodide in sufficient distilled water to obtain 1 liter of liquid. It is identical with the test-solution of mercuric-potassium iodide of the U. S. P., and is an excellent qualitative test for the presence of alkaloids, which must be applied in acidulated aqueous solutions, free from alcohol, chloroform, etc. For the quantitative determination of alkaloids, Mayer's Solution is not well suited, since the titration equivalent (amount of alkaloid precipitated by 1 Cc. of the reagent) has been found to vary in many cases with the acidity and dilution of the alkaloidal solutions.

Action and Uses.—The red iodide of mercury is a far more irritant and poisonous preparation than the yellow iodide, producing death when taken internally in overdose in a manner similar to that caused by the bichloride. Violent gastro-intestinal irritation and inflammation, abdominal pain, vomiting, and even convulsions may ensue. The antidote is white of egg.

The red iodide is used in medicine as an antisyphilitic, but as it is irritating it cannot be given freely. Its dose for this purpose is $\frac{1}{16}$ grain (0.004 Gm.), 3 times a day, gradually increased to larger amounts if the stomach will stand it.

Locally the red iodide has been employed as an antisyphilitic lotion and in concentrated form as a caustic to growths on the skin, particularly in cases of lupus. When it is used as an antiseptic the strength of its solution should be about 1 to 5000 to 1 to 1000.

HYDRARGYRI OXIDUM FLAVUM, *U. S., Br.*—Yellow Mercuric Oxide.

Hydrargyrum oxydatum via humida paratum, P. G.; *Hydrargyrum oxydatum præcipitatum (vel flavum).—Precipitated oxide of mercury, or Mercuric oxide*, E.; *Oxyde mercurique jaune (précipité)*, *Deutoxyde jaune de mercure*, Fr.; *Präcipitirtes (Gelbes) Quecksilberoxyd*, G.

Formula, HgO. Molecular weight, 214.38.

It should contain not less than 99.5 per cent. of pure salt.—U. S.

Preparation.—Corrosive mercuric chloride, 100 Gm.; soda, 40 Gm.; distilled water, a sufficient quantity. Dissolve the corrosive mercuric chloride in 1000 Cc. of warm distilled water, and filter the solution. Dissolve the soda (which should contain 90 per cent. of sodium hydroxide) in 1000 Cc. of cold distilled water, and into this solution pour gradually, and with constant stirring, the solution of corrosive mercuric chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by the affusion and decantation of distilled water, using 1000 Cc. of water each time; collect the precipitate on a strainer, and continue the washing with warm distilled water until a small portion of the washings, when poured on a little mercuric chloride test-solution, no longer affords a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.). Keep the product in well-stoppered bottles, protected from light.—U. S.

The Br. P. (1898) has dropped the process of manufacture.

On mixing solutions of mercuric chloride and soda, sodium chloride, water, and mercuric oxide are formed, the latter being precipitated: $HgCl_2 + 2NaOH$ yields $2NaCl + H_2O + HgO$. The alkali must be in excess, lest some mercuric oxychloride be precipitated with the oxide, and it is essential to pour the mercuric solution into the alkali. The foregoing equation shows that 270.54 parts of mercuric chloride require 79.92 parts of sodium hydroxide for complete decomposition, and as the Pharmacopœia orders for 100 parts of mercuric chloride 40 parts of soda containing at least 90 per cent. of NaOH, the necessary excess is assured, for 40 at 90 per cent. = 36, and 100 parts of $HgCl_2$ require only 29.9 parts of NaOH. If the soda is contaminated with carbonate, brown mercuric carbonate will also be precipitated, and it is therefore essential that pure alkali be used.

Of great importance for the appearance of the oxide is the temperature at which it is prepared; the lower it be kept the brighter will be the yellow color, while with an elevation of temperature the red tint will become more decided. The yield is nearly 60 per cent.

Properties and Tests.—Yellow mercuric oxide is a heavy, smooth, impalpable, amorphous, yellow or reddish-yellow powder, which is not altered in the air, but on exposure to light becomes dark, in consequence of partial reduction to mercurous oxide; when heated, it assumes a red color, and at a sufficiently strong heat is decomposed and volatilized like red mercuric oxide. It has the specific gravity 11.0, is without odor or taste, and is insoluble in water and other simple solvents, but dissolves readily and completely without effervescence in diluted hydrochloric or nitric acid. When digested or agitated with a solution of oxalic acid it forms white mercuric oxalate (difference from red oxide). Heated with an alcoholic solution of mercuric chloride, it speedily turns black from the formation of an oxychloride; red mercuric oxide slowly undergoes a similar change (Roucher). It should be completely volatilized by heat, and its solution in dilute nitric acid should become merely opalescent on the addition of silver nitrate test-solution (limit of chloride). 0.5 Gm. of the oxide dissolved in 2 Cc. of hydrochloric acid and 25 Cc. of water should not respond to the tests for foreign salts, metals, or arsenic given under HYDRARGYRI CHLORIDUM CORROSIVUM.

The yellow oxide is much more finely divided than the red, and hence is much more easily acted on chemically and has a stronger therapeutic action.

Action and Uses.—Yellow oxide of mercury is used in medicine as a local application in the form of an ointment to cure and prevent the formation of styes, and in the treatment of conjunctivitis, blepharitis, etc., in the strength of 2 grains (0.12 Gm.) to the ounce (30 Gm.) of lard or lanolin. Held in solution in olive oil, it has been used by some physicians hypodermically in the treatment of syphilis, but it has not been a popular remedy for this disease.

HYDRARGYRI OXIDUM RUBRUM, *U. S., Br.*—Red Mercuric Oxide.

Hydrargyrum oxydatum, P. G.—*Peroxide of mercury, Red precipitate.* E.; *Deutoxyde (Peroxyde) rouge de mercure, Oxyde mercurique, Précipité rouge, Poudre de Jean de Vigo*, Fr.; *Rothes Quecksilberoxyd, Rother Präcipitat (Quecksilber-Präcipitat)*, G.

Formula, HgO. Molecular weight, 214.38.

It should contain not less than 99.5 per cent. of pure oxide, and should be kept in well-corked bottles, protected from light.—U. S.

Preparation.—None of the pharmacopœias give a method of preparation. Red mercuric oxide is made on a large scale by heating mercuric nitrate, or an intimate mixture of molecular quantities of mercuric nitrate and mercury, until acid vapors cease to escape, The temperature must not be allowed to rise too high, else the mercuric oxide formed will be decomposed into mercury and oxygen. When mercuric nitrate alone is heated, it is decomposed thus: $Hg(NO_3)_2 = HgO + 2NO_2 + O$. Red fumes of nitrogen peroxide mixed with oxygen are given off. To avoid the loss of oxygen, a mixture of the nitrate with mercury is often used, where the change is represented thus: $Hg(NO_3)_2 + Hg = 2HgO + 2NO_2$. Occasionally a minute quantity of nitrate remains undecomposed.

Should the nitric acid employed be contaminated with hydrochloric acid, a corresponding quantity of mercuric chloride, and finally oxychloride, would be formed, the latter remaining with the mercuric oxide as an impurity. The last traces of acid may be removed by boiling with diluted sodium hydroxide solution.

The preparation formerly official in various pharmacopœias as *Mercurius præcipitatus per se* or *Mercurius calcinatus* was red oxide of mercury in the form of crystalline scales, which are obtained by keeping metallic mercury in a loosely covered flask or retort at a temperature near its boiling-point. The process required several weeks for its completion.

Properties.—When made on a small scale, red mercuric oxide is a finely granular powder of a yellowish-red color, without luster; but made in larger quantities it is obtained in the form of bright brownish-red shining crystalline scales, which on trituration yield a fine orange-red powder, the yellowish tint increasing with the fineness of the powder. It is inodorous, and at first tasteless, but slowly develops a metallic taste. It is very slightly soluble in water and other simple solvents, but completely soluble in diluted hydrochloric and nitric acids. It is permanent in the air if kept in the dark, but on exposure to light it becomes superficially black—however, much more slowly than the yellow oxide. When heated, its color is changed to dark-red, brown, and near 400° C. (750° F.) to black, the original color reappearing on cooling; but at a red heat it is completely decomposed into metal and oxygen. The oxide, being easily decomposed, forms explosive mixtures with such bodies as sulphur, carbon, phosphorus, when heated or struck. It is reduced by many substances, such as sulphurous and phosphorous acids, fats, gums, sugar, etc. Hence weak ointments of the oxide made with lard become decolorized or gray after a time.

Tests.—When strongly heated, mercuric oxide should not give off red nitrous vapors (absence of nitrate), and when heated to full redness it should be decomposed and volatilized without residue (absence of non-volatile impurities). On being agitated or digested with a solution of oxalic acid in 10 parts of water the red color should not be changed (difference from yellow mercuric oxide). Treated with diluted nitric acid in excess, it should yield a colorless solution. A red-colored residue would indicate the presence of brick-dust or of vermilion, the latter being volatilizable by heat; a brown residue (of puce-colored oxide of lead) would prove adulteration with red lead, and the nitric acid solution would contain lead, recognizable by the white precipitate appearing on the addition of a little sulphuric acid. The nitric acid solution should remain undisturbed or merely become slightly opalescent on the addition of silver nitrate test-solution (limit of chloride).—U. S. If to 1 Gm. of red mercuric oxide 5 Cc. of water be added, followed by 2 Cc. of sulphuric acid, and after cooling 1 Cc. of concentrated solution of ferrous sulphate be carefully poured upon the acid mixture, a brown color should not appear at the junction of the two liquids (absence of nitrate). 0.5 Gm., dissolved in 2 Cc. of hydrochloric acid and 25 Cc. of water, should not respond to the tests for foreign salts, metals, or arsenic given under HYDRARGYRI CHLORIDUM CORROSIVUM.

Action and Uses.—Red precipitate is used as a dusting-powder on syphilitic ulcers, usually diluted at least one-half with some inert powder. It may also be employed in ointment in the treatment of the same conditions in the form of the official ointment (see UNGUENTUM HYDRARGYRI OXIDI RUBRI), which should be diluted one-half with lard.

HYDRARGYRI SALICYLAS.—Mercuric Salicylate.

Hydrargyrum salicylicum, P. G.; *Salicylate mercurique*, Fr.; *Mercurisalicylat, Salicylsaures Quecksilberoxyd*, G.

Formula, $C_6H_4<\begin{matrix}O\\CO_2\end{matrix}>Hg$. Molecular weight, 333.51.

Preparation.—Dissolve 27 parts of corrosive sublimate in 600 parts of water, precipitate mercuric oxide from this, as described under HYDRARGYRI OXIDUM FLAVUM, by adding it to a mixture of 85 parts of sodium hydroxide solution (specific gravity 1.178–1.182) and 200 parts of water. The oxide, properly washed, is digested in a flask with a little water and 15 parts of salicylic acid, on a boiling water-bath, until the mixture has become pure white. The mercury salicylate is then filtered and washed until the filtrate is no longer acid in reaction, dried on porous plates at 30°–40° C. (86°–104° F.), and finally at 100° C. (212° F.).

Properties.—It forms a very fine, white, amorphous, tasteless and odorless powder, neutral to litmus, insoluble in water and alcohol. It is not decomposed by hydrogen sulphide or ammonium sulphide. It is stable toward weak acids, such as carbonic, acetic, tartaric, lactic; but it is decomposed by concentrated hydrochloric, nitric, sulphuric, and nitrohydrochloric acids. Solutions made with the latter acids give a black mercuric sulphide with hydrogen sulphide.

The salt is soluble at ordinary temperature in sodium hydroxide or sodium carbonate solution, forming a double salt; it is reprecipitated from such a solution by a weak acid, as acetic. Solutions of chlorides, bromides, and iodides, when warmed, dissolve the salt; but on cooling a double salt separates, containing 1 molecule of the halogen salt to 1 of the salicylate. It contains at least 59 per cent. of mercury.

Tests.—If 0.1 Gm. of the salt be shaken with 5 Cc. of water, the liquid will assume a violet color with a drop of ferric chloride solution (salicylic acid). The salt, when heated in a dry tube, gives a sublimate of mercury. Heated in a porcelain crucible in the air, no residue should be left (absence of sodium salicylate), and it should have no acid reaction to litmus-paper (absence of salicylic acid). 0.5 Gm. converted into chloride by evaporating to dryness with 7 Cc. of nitric and 21 Cc. of hydrochloric acid, should yield not less than 0.34 Gm. of mercuric sulphide, when the residue is taken up with dilute hydrochloric acid and treated with hydrogen sulphide, corresponding to 58.6 per cent. of mercury.

Action and Uses.—Salicylate of mercury is used in the dose of from $\frac{1}{8}$ to 1 grain (0.008–0.06 Gm.) in the treatment of secondary syphilis, and as an ointment (16 grains to the ounce (1.05–30 Gm.) of lard) for lesions of the skin.

HYDRARGYRUM, *U. S., Br., P. G.*—Mercury.

Hydrargyrum vivum, Mercurius vivus, Argentum vivum.—Quicksilver, E.; *Mercure, Vifargent*, Fr.; *Quecksilber*, G.

Symbol, Hg. Atomicity univalent and bivalent. Atomic weight, 198.50.

It should be 99.9 per cent. pure, and be kept in strong bottles.—U. S.

Origin.—Mercury became known before the Christian era, but long after silver and gold had been in use. It is principally obtained from New Almaden, in California, from Peru, China, Idria, in Austria, and Almaden, in Spain. It is found to some extent in the metallic state in the form of minute or large globules, also in combination with oxygen, chlorine, selenium, etc.; but the principal ore for extracting it is *cinnabar*, which is the sulphide.

Preparation.—Most of the mercury is obtained by roasting the ore in a kiln. It is placed upon an arch of brickwork containing several openings, through which the flames pass, whereby the sulphur of the ore is ignited and burns, air being admitted at the same time; the heat thus produced volatilizes the mercury, the vapors of which, mingled with the smoke and sulphur dioxide gas, are passed through a series of condensing-chambers, where the metal is condensed, the incondensable gases finally escaping through the flue. This is essentially the process as carried on at Idria and New Almaden; like-

wise at Almaden, except that the vapors are passed through the so-called *aludels*, consisting of cylinders adapted to each other, first in a descending and then in an ascending direction, where most of the mercury is condensed and collects in a gutter placed under the angle, the remainder being condensed in a large terminal chamber, from which the gases pass into the flue. In the Palatinate the cinnabar is mixed with lime, and in Bohemia with hammerslag, and then distilled, calcium sulphide remaining behind in the former, and sulphide of iron in the latter, case.

Mercury appears in commerce in cylindrical iron flasks containing 75 pounds each. In this condition it still contains small quantities of other metals, as lead, bismuth, copper, antimony, tin silver, which, however, do not interfere with its uses in the silvering of looking-glasses, in the amalgamation process for the extraction of gold and silver, nor in the preparation of some chemicals. For barometers and thermometers, as well as for some pharmaceutical preparations, a purification of the metal is required or advisable, and may be effected by distillation or by the following process directed in several European pharmacopœias:

Hydrargyrum Depuratum s. Purificatum.—Take of mercury, 100 parts; nitric acid, distilled water, each, 5 parts. Digest in a suitable vessel for 3 days, shaking frequently. Having poured off the acid liquid, wash well the mercury with distilled water, and dry it completely.

The operation is conducted best in a broad glass or porcelain vessel, so as to expose a very large surface of the metal to the action of the dilute acid; or, as proposed by L. Meyer, by allowing the mercury to run slowly in a fine stream into a long glass tube containing the diluted acid. Lead, iron, and other metals, being far more easily oxidized and dissolved than the mercury, are thereby removed, though a little of the latter likewise passes into solution. After washing, most of the water may be removed by bibulous paper. These metals may also be removed by agitating the crude mercury with concentrated sulphuric acid or with solution of ferric chloride, the latter process being preferable for operations on a small scale.

Absolutely pure mercury may be obtained by distilling a mixture of pure precipitated mercuric sulphide with quicklime or iron filings.

Properties.—Mercury is solid at a temperature of —39.44° C. (—39° F.), and crystallizes in octahedrons and needles, which are ductile and may be cut with a knife. At the ordinary temperature it forms a bright silvery, lustrous, inodorous, and tasteless liquid, which is very cohering, and not adhering to glass or paper unless it be impure, when small globules will *tail* or leave a streak upon it. When triturated with sugar, fat, various salts, oil of turpentine, etc., it is converted into a gray powder consisting of minute globules separated by the foreign substances and running together again on their removal; this finely divided state is called the *extinction* of mercury, and is accomplished in making mercurial ointment and several other official preparations. Mercury has at 4° C. (39.2° F.) the specific gravity 13.59, and at 15° C. (59° F.) 13.5584. It boils at about 357.2° C. (675° F.), giving a colorless vapor of 6.98 specific gravity, and leaving no residue; it volatilizes very slowly even at the ordinary temperature. It is permanent at the ordinary temperature, the whitish pellicle which forms upon the surface of commercial mercury being due to the presence of foreign metals (lead, zinc, etc.). It unites directly with chlorine, bromine, and iodine, and dissolves completely even in dilute nitric acid, with the evolution of nitric oxide. All simple solvents and boiling hydrochloric and dilute sulphuric acids are without action upon it, but hot concentrated sulphuric acid dissolves the metal, sulphur dioxide being given off. When heated to near its boiling-point in contact with the atmosphere it combines with oxygen, forming scales of red oxide.

Mercury unites with oxygen in two proportions, and forms two series of salts, the *mercurous* and *mercuric*. In the latter salts the valence of mercury is 2, but vapor density determinations point to the conclusion, that in the mercurous salts the valence of mercury is 1 (see under HYDRARGYRI CHLORIDUM MITE).

Mercurous compounds are readily converted into mercuric compounds by the action of oxidizing agents, and the latter are easily converted into the former by the action of reducing agents. All soluble salts of mercury are poisonous, have a strong metallic taste, and mostly an acid reaction upon test-paper. The normal salts are usually white, and the basic salts yellow; treated with stannous chloride, phosphorous or sulphurous acid, or other deoxidizing agents, they are blackened, and finally reduced to metal. Their

solutions deposit a silvery coating of metallic mercury upon a bright piece of metallic copper, and yield black precipitates with hydrogen sulphide and white ones with sodium phosphate. *Mercurous* salts yield black precipitates with potassium hydroxide, ammonia, and, on boiling, also with alkali carbonates. Hydrochloric acid causes a white precipitate of calomel, and potassium iodide separates a greenish-yellow iodide. *Mercuric* salts yield with potassium or sodium hydroxide, if added in insufficient quantity, brown-red, and if added in excess yellow, precipitates—with ammonia and ammonium carbonate white, and with potassium or sodium carbonate red-brown, precipitates. Hydrochloric acid does not disturb the solutions; potassium iodide causes a scarlet-red precipitate, which is soluble in an excess of either solution. All compounds of mercury are either volatilized or decomposed by heat. The vapor density of mercury shows that the molecule is identical with the atom—*i. e.*, the molecular and atomic weights are the same.

Amalgams.—The alloys which mercury forms with other metals are called *amalgams.* They are generally obtained without difficulty simply by bringing mercury in contact with the metals. Amalgams of sodium, ammonium, silver, and gold are among those of chief interest. Amalgams vary in consistency according to the amount of mercury present. Several varieties of amalgams are employed in dentistry, containing gold, tin and silver, tin and cadmium, gold and copper, gold and tin, tin and silver.

Tests.—The purity of mercury is ascertained from its behavior and properties as described above. When mercury is agitated for a few minutes with the official solution of ferric chloride, which is free from ferrous chloride, the liquid should afterward not yield a blue precipitate on the addition of potassium ferricyanide, which would result through the solution of a foreign metal and the reduction of some ferric to ferrous chloride; nor should the liquid, after being acidulated with hydrochloric acid if necessary, yield more than a mere trace of a colored precipitate on the addition of hydrogen sulphide. Hager's test for distinguishing the purified from crude mercury has been adopted by the U. S. P., as follows: On boiling 5 Gm. of distilled water with 5 Gm. of mercury, and 4.5 Gm. (1.5 Gm., Hager) of sodium thiosulphate, in a test-tube for about 1 minute, the mercury should not lose its luster, and should not acquire more than a slightly yellowish shade (absence of more than slight traces of foreign metals).

Commercial.—The importation of mercury from Spain and Austria has gradually fallen off until at present the production of the American mines is more than sufficient for our needs. This country produced 2,224,540 pounds of mercury in 1897, the world's production for the same year being 8,550,000 pounds. The exported mercury goes principally to China, Chili, Peru, and Mexico.

Action and Uses.—Metallic mercury produces when rapidly absorbed a chain of symptoms which is very characteristic. The most notable of these is salivation, or ptyalism, and associated with this are great fetor of the breath, swelling of the mucous membrane of the mouth, and general wretchedness, with more or less intestinal disturbance. If the drug is continued, wasting of the mamma or of the testicles is said to occur, and the condition of the patient is one of greatly diminished vitality. When the drug is absorbed gradually over a long period of time, as in artisans handling it or inhaling its fumes, it is apt to cause neuritis and symptoms of paralysis agitans or chorea.

When one of the soluble salts of mercury, of which the bichloride is probably the most notable, is taken in excess, it usually acts as a more or less active gastro-intestinal irritant, death ensuing rapidly when these salts are taken, because of the intense gastro-enteritis produced. The antidote to the bichloride and the biniodide is white of egg, to form an insoluble albuminate of mercury.

When mercury is given in medicinal doses, it acts in the body as an alterative—that is, as a substance which influences the nutrition of the tissues. How it does this is not known. All medicinal preparations of mercury capable of being taken internally are regarded as being possessed of specific curative influence in syphilis. Locally applied, certain medicinal preparations have a most favorable effect on external syphilitic lesions in many instances. How mercury does good in syphilis is not known, and will not be till the cause of syphilis is discovered.

Practically all the preparations of mercury increase the flow of bile in the stools, but whether they do this by stimulating the liver to an increased secretion of this fluid or by causing the gall-bladder to expel it in excess, is not known. That they do cause bile to appear in the stools is a well-known fact, although experimental studies indicate that

even calomel does not act as a cholagogue. Some mercurial drugs affect the liver much more than others (see MASSA HYDRARGYRI and HYDRARGYRI CHLORIDUM MITE).

At one time the various preparations of mercury were largely used with the idea that they possessed distinct antiphlogistic effects in inflammations of serous membranes, such as meningitis, peritonitis, pericarditis, etc. This practice has largely gone out of favor.

For the disinfectant and antiseptic properties of mercury, see HYDRARGYRI CHLORIDUM CORROSIVUM.

COMPOUNDS OF MERCURY.

Hydrargyri Acetas. *Mercurous acetate*, E.; *Mercuroacetat*, G. CH_3COOHg.—White, satiny, scaly crystals soluble in 330 parts of water, insoluble in alcohol and ether. It is decomposed when boiled with water, and by exposure to light, into mercury and mercuric acetate. It should be kept dry and away from the light. It is used as a wash (1 in 500–300) in skin diseases, or in ointment (1 in 20–10). It is given internally in pills in from $\frac{1}{6}$ to 1 grain (0.01–0.05 Gm.), for syphilis.

Mercuric Acetate. $(CH_3COO)_2Hg$.—Colorless, glistening plates, soluble in 4 parts of water, also in alcohol and ether. The aqueous solution gradually gives off acetic acid, and the surface becomes yellow by the formation of a basic acetate. It is used as a wash (1 in 300) for freckles, and internally as an antisyphilitic in doses of from $\frac{1}{6}$ to 1 grain (0.01–0.06 Gm.), 2 or 3 times daily.

Hydrargyri Albuminas. *Mercuric albuminate*, E.; *Quecksilberalbuminat*, G.—The composition of this body is not constant. It is obtained by adding 4 per cent. mercuric chloride solution to a solution of dried egg albumin (1 in 8) and heating. The albumin is kept in excess, so that the filtrate still gives a precipitate with the mercuric chloride solution. After 48 hours the moist precipitate is rendered dry by mixing with milk-sugar, which, after thorough drying in a desiccator over sulphuric acid, is diluted with milk-sugar until the mercury present corresponds to 0.4 per cent. of mercuric chloride. Blood-serum, sodium chloride, or potassium iodide, separates mercuric chloride from the albuminate. It is used as an antiseptic powder in surgery.

Hydrargyri Amidopropionas. *Mercuric amidopropionate* or *alanate*, *Alanin-mercury*, E.; *Alanin-Quecksilber*, G. $(CH_3CH.NH_2.CO_2)_2Hg$.—Obtained by dissolving mercuric oxide in amidopropionic acid and crystallizing in the usual way. It forms colorless needles, soluble in 3 parts of water. It was one of the first organic mercury compounds to be used therapeutically which does not precipitate albumin. It was used in 0.5 per cent. aqueous solution for subcutaneous injection in syphilis in place of corrosive sublimate.

Hydrargyri Amidosuccinamas. *Mercuric amidosuccinamate*, *Asparagin-mercury*, E.; *Asparagin-Quecksilber*, G. $Hg(C_4H_7N_2O_3)_3$.—Obtained by dissolving mercuric oxide in a warm solution of asparagin, and crystallizing. Colorless needles, soluble in water, used subcutaneously in syphilis in 1 per cent. solution.

Hydrargyri Benzoas. *Mercuric benzoate*, E.; *Mercuri-benzoat*, G.; *Benzoate mercurique*, Fr. $(C_6H_5COO)_2Hg$.—Prepared in the same manner as MERCURIC SALICYLATE (which see), by digesting the oxide from 27 parts of mercuric chloride with 22–23 parts of benzoic acid and 2000 parts of water. The benzoate is recrystallized from much hot water and dried at 50° C. (122° F.). It consists of colorless, glistening, inodorous needles, slightly soluble in water, but easily soluble in a solution of sodium chloride. It gives a precipitate with albumin, which, however, is soluble in sodium chloride solution. The salt contains 45.2 per cent. of mercury. It is used for injections in syphilis, 3 parts of the benzoate, 1 part of sodium chloride to 400 parts of water; and for urethral injections, 0.1 per cent. solution with an equal quantity of sodium chloride may be used.

Hydrargyri Bromidum Corrosivum. *Mercuric bromide*, E.; *Bromide de mercure*, Fr.; *Quecksilberperbromid*, *Mercuribromid*, G. $HgBr_2$.—Obtained by shaking together 10 parts of mercury, 8.5 parts of bromine, and 120 parts of water, and crystallizing the product from hot water. It is a white crystalline powder, less soluble in water, alcohol, or ether than the chloride. It is soluble in 10 parts of hot or 80 parts of cold water. It is employed as is the corrosive chloride, but much more seldom.

Hydrargyri Bromidum Mite. *Mercurous bromide*, E.; *Bromure de mercure*, Fr.; *Quecksilberbromür*, *Mercurobromid*, G. HgBr.—Obtained by precipitation of mercurous nitrate with potassium bromide, or by subliming a mixture of mercury and mercuric bromide—the procedure being exactly as in the case of calomel. It is very like calomel in its physical and chemical properties. It is given comparatively seldom, under the same indications and dose as calomel.

Hydrargyri Carbolas s. Phenas. *Hydrargyrum carbolicum s. phenylicum s. phenolicum*; *Mercuric carbolate*, *phenolate*, or *phenylate*, E.; *Neutrales Quecksilberphenolat*, *Diphenol-Quecksilber*, G. $(C_6H_5O)_2Hg$.—Two preparations occur under this name, *Gamberini's* basic mercuric phenate, $(C_6H_5O)HgOH$, and *Merck's* normal mercuric phenate or mercuric diphenate,

$Hg(OC_6H_5)_2$; the latter is a stable combination, and should be dispensed whenever mercuric phenate is prescribed. It is prepared by dissolving 188 parts of liquefied carbolic acid and 56 parts of potassium hydroxide in just sufficient alcohol with the aid of heat, and adding to this under constant stirring an alcoholic solution of 135 parts of mercuric chloride: a yellowish-colored precipitate is formed, which becomes almost colorless as the mass is evaporated to dryness. After washing with hot water slightly acidulated with acetic acid the salt is crystallized from hot alcohol. It is usually given in pill-form to adults in doses of from $\frac{1}{3}$ to $\frac{1}{2}$ grain (0.02–0.03 Gm.), twice daily.

Hydrargyri Chloridi Carbamidum. *Hydrargyrum bichloratum carbamidatum solutum, Solution of mercuric chloride-urea.*—This was introduced for hypodermic use by Schutz and Doutrelepont. As the solution readily changes, it should be prepared extemporaneously as follows: 1 Gm. of mercuric chloride is dissolved in 100 Cc. of hot water, and when cold 5 Gm. of urea are added and the liquid filtered. The daily dose is 15 minims (1 Cc.), corresponding to $\frac{1}{6}$ grain (0.01 Gm.) of mercuric chloride.

Hydrargyri Formamidum. *Hydrargyrum formamidatum solutum. Solution of mercuric formamide,* E.; *Quecksilberformamidlösung,* G.—Solution of mercuric formamide, $(HCONH)_2Hg$, was first introduced by Liebreich for hypodermic use in the treatment of syphilis, in daily doses of 16 minims (1 Cc.), which corresponds to about $\frac{1}{6}$ grain (0.01 Gm.) of mercuric chloride. It is prepared by dissolving the freshly precipitated oxide obtained from 10 Gm. of mercuric chloride in a sufficient quantity of formamide and adding sufficient distilled water to bring the volume up to 1000 Cc. The solution does not precipitate albumin; when boiled with acids or alkalies, or exposed to light, metallic mercury is precipitated.

Hydrargyri Gallas. *Mercuric gallate,* E.; *Mercurigallat,* G. $[C_6H_2(OH)_3CO_2]Hg$.—Equivalent quantities of gallic acid and moist precipitated mercuric oxide are rubbed together and dried in the dark in a sulphuric acid desiccator. It is a greenish or blackish powder, containing, besides the gallate, oxidation-products of gallic acid, mercuric oxide, and reduced mercury, insoluble in ordinary solvents. It is used as an antisyphilitic in place of the less stable tannate, in doses of from $\frac{1}{2}$ to 1 grain (0.03–0.06 Gm.), daily.

Hydrargyri Iodas. *Mercuric iodate,* E.; *Mercurijodat,* G. $Hg(IO_3)_2$.—Obtained by digesting moist precipitated mercuric oxide with a solution of iodic acid on a water-bath, and washing and drying the salt. It is insoluble in water, but soluble in a solution of sodium chloride or potassium iodide. It is used as an antisyphilitic injection, for which 1.2 parts of the salt and 0.8 part of potassium iodide are dissolved in 100 parts of water. Salivation or other unfavorable effects are said not to be produced by it. Dose, $\frac{1}{6}$ grain (0.01 Gm.).

Hydrargyri Naphtolas. *Mercuric naphtolate, Naphtol-Quecksilber.* $(C_{10}H_7O)_2Hg$.—Obtained by precipitating a solution of mercuric nitrate by a solution of sodium beta-naphtolate. It is a yellowish-white, odorless powder, soluble in caustic alkali but not in a solution of sodium chloride. It is used for injections, like the salicylate, in the dose of from $\frac{1}{6}$ to $\frac{1}{3}$ grain (0.01–0.02 Gm.).

Mercuric naphtol-acetate, $(C_{10}H_7O)C_2H_3O_2.Hg$, is a double salt which crystallizes out when the naphtolate is dissolved in excess of mercuric acetate. The colorless needles, soluble in alcohol, ether, and chloroform, are used for the same purposes as the naphtolate.

Hydrargyri Nitras. *Mercurous and Mercuric nitrate,* E.; *Azotate mercureux et Azotate mercurique,* Fr.; *Mercuronitrat und Mercurinitrat,* G. $HgNO_3.H_2O$ and $Hg(NO_3)_2.H_2O$.—Mercurous nitrate is obtained by the action of cold nitric acid of about 25 per cent. on an excess of mercury. The crystals which form on the mercury are dissolved by warming, and the solution is then poured off and allowed to crystallize in a cool place. It forms colorless or slightly yellow prismatic crystals, having an acid reaction and a metallic taste, and soluble in an equal quantity of warm water, preferably with addition of a few drops of nitric acid. It is decomposed by a large volume of water into a soluble acid nitrate and an insoluble yellow basic nitrate, the composition of which varies with the bulk and temperature of the water. Caustic alkalies decompose it, giving a dark precipitate of mercurous oxide, Hg_2O. Ammonia water gives a dark precipitate consisting of mercury and a compound of the formula $(NH_2HgNO_3)_2HgO$. The presence of basic salt gives to mercurous nitrate a yellow tint. A solution of the salt may be kept free from mercuric nitrate by adding metallic mercury to the solution. The dry salt should be kept in small well-stoppered bottles. Mercuric nitrate is usually employed in solution, and may be prepared by dissolving 1 part of mercuric oxide in 2.5 parts of nitric acid of about 25 per cent.; crystals can be obtained by evaporating the solution over sulphuric acid. The salt is stable only in the presence of acid (nitric). Water alone decomposes it, forming an insoluble basic salt. Mercuric nitrate may also be obtained by dissolving mercury in excess of nitric acid. (See LIQUOR HYDRARGYRI NITRATIS and UNGUENTUM HYDRARGYRI NITRATIS.)

Hydrargyri Paraphenolsulphonas. *Mercuric paraphenolsulphonate,* E.; *para-Phenolsulfosaures Quecksilber,* G. *Hydrargyrol.*—Obtained by dissolving yellow mercuric oxide in a solution of p-phenolsulphonic acid and evaporating to dryness. It occurs in brownish scales, with an odor like ginger-cake, insoluble in absolute alcohol, decomposed by dilute alcohol or acetic acid, soluble in water, forming a red solution in which neither mercury nor phenol

responds to the usual tests. The aqueous solution does not precipitate albumin, but alkaloids, and does not attack iron and nickel, nor is it corrosive. A 0.4 per cent. solution is said to be a thorough sterilizer, especially when hot. It is far less poisonous than corrosive sublimate.

Asterol is a combination of the above salt with ammonium tartrate. It is a nearly white powder, slowly soluble in cold, more readily in hot water, with an acid reaction and contains 14 per cent. of mercury. It is intended to displace corrosive sublimate as an antiseptic, since it does not precipitate albumin, does not act on iron, and is less poisonous than sublimate although accomplishing the same results as an antiseptic. It is used in 0.2–0.4 per cent. solution.

Hydrargyri Peptonas. *Hydrargyrum peptonatum solutum. Solution of mercuric peptonate.*—The mercury compound is first obtained by mixing a solution of 1 Gm. of mercuric chloride in 20 Cc. of water with a solution of 3 Gm. of dry peptone in 10 Cc. of water; after the lapse of an hour the precipitate is collected on a filter, drained, and added to a solution of 3 Gm. of sodium chloride in 47 Cc. of water; solution is effected by agitation and sufficient water then added to bring the final volume up to 100 Cc. The solution should only be used when clear and free from sediment; the daily dose hypodermically for syphilis is 1 Cc., corresponding to $\frac{1}{6}$ grain (0.01 Gm.) of mercuric chloride.

Hydrargyri Pyroboras. *Mercuric pyroborate or borate*, E.; *Borate de mercure*, Fr.; *Mercuriborat*, G. HgB_4O_7.—Obtained by pouring a solution of borax into one of mercuric chloride, while stirring. It is an amorphous brown powder, insoluble in water or alcohol, soluble in hydrochloric or nitric acid, and contains 56.2 per cent. of mercury. It is used in ointment or as dusting-powder on moist wounds.

Hydrargyri Sozoiodolas. *Mercuric sozoiodolate*, E.; *Sozoiodol-Quecksilber*, G. $C_6H_2I_2O.SO_3.Hg$.—Obtained by mixing solutions of mercuric nitrate and sodium sozoiodolate (di-iodo-paraphenolsulphonate) as a fine yellow powder, soluble in 500 parts of water, and easily soluble in sodium chloride solution. A 10 per cent. solution is caustic. The salt is employed chiefly in syphilis: dose for subcutaneous injection, 1 grain (0.06 Gm.); for local application, 1–2 per cent. ointment, or in dry powder, or wash.

Hydrargyri Subsulphas Flavus (U. S. 1890). *Hydrargyrum sulphuricum basicum. Yellow mercuric sulphate, Basic mercuric sulphate, Turpeth mineral*, E.; *Soussulfate mercurique*, Fr.; *Mercurisubsulfat, Mineralischer Turpeth*, G. $HgSO_4.2HgO$.—This preparation, which is very rarely used, is made by adding in small portions finely powdered mercury sulphate obtained from 100 Gm. of mercury to 2000 Cc. of boiling water while constantly stirring, and continuing the boiling for 10 minutes after all has been added. The precipitate is filtered and thoroughly washed with warm water and dried at moderate temperature. On adding the normal sulphate to boiling water it is converted into basic sulphate, while an acid sulphate remains in solution. The result varies somewhat, depending upon the amount and the temperature of the water. Using boiling water in the above proportions, the yield will be about 75 per cent. of the weight of the dry mercuric sulphate used. The same compound is also formed by slowly pouring a solution of mercuric nitrate into an excess of a boiling solution of sodium sulphate. Yellow mercuric subsulphate is a heavy, bright lemon-yellow powder, which has the specific gravity 6.44, is permanent in the air, inodorous, has a slight metallic taste, on heating becomes red, and yellow again on cooling; at a red heat it is completely volatilized. It is insoluble in alcohol and ether, requires 2000 parts of cold and 600 parts of boiling water for solution, is decomposed by potassium hydroxide solution, yellow mercuric oxide being formed, and dissolves completely in sulphuric, nitric, or hydrochloric acid, the latter solution, according to Mohr, containing corrosive sublimate and free sulphuric acid. The salt should be soluble in 10 parts of hydrochloric acid without residue (absence of mercurous salt or of lead). The presence of nitrate is detected by sulphuric acid and ferrous sulphate in the same manner as stated for red mercuric oxide. Non-volatile impurities are left behind on heating to bright redness. Turpeth mineral is a powerful emetic, alterative, and in large dose corrosive poison. In poisonous dose it produces the same symptoms as corrosive sublimate (see HYDRARGYRI CHLORIDUM CORROSIVUM). This remedy was formerly employed in the treatment of croup, but at the present time has largely fallen into disuse. The dose for a child 2 years old is from 2 to 4 grains (0.10–0.25 Gm.).

Hydrargyri Sulphas. *Hydrargyrum sulphuricum. Mercuric sulphate, Normal mercuric sulphate*, E.; *Sulfate mercurique*, Fr.; *Mercurisulfat*, G. $HgSO_4$.—This salt is prepared by heating on a sand-bath until reddish vapors cease to be given off, 18 parts of mercury, 10 parts of concentrated sulphuric acid, 3 parts of water, and 4 parts of nitric acid of about 25 per cent., in a flask. The contents are then dried on a sand-bath in a porcelain dish while constantly stirring. It is a heavy white crystalline powder which, on being mixed with a small quantity of water, is at first colored yellow, but after some time is converted into colorless shining prisms or silvery scales of the hydrated salt $HgSO_4.H_2O$. A larger quantity of water decomposes it permanently into yellow basic sulphate. When heated to redness it is decomposed into mercury, oxygen, sulphurous acid, and mercurous sulphate, and is finally completely volatilized. It is employed for the preparation of turpeth mineral, corrosive sublimate, and calomel. It is not used in medicine.

Hydrargyri Sulphidum Nigrum s. Æthiops Mineralis. *Black sulphide of mercury*, E.; *Sulfure noir de Mercure*, Fr.; *Quecksilbermohr, Schwarzes Schwefelquecksilber*, G.—This preparation is no longer official in any of the pharmacopœias. It was made by triturating equal weights of mercury and sulphur until all metallic globules disappeared. It forms a fine black and heavy powder, which, when viewed with a lens, does not show any globules of uncombined mercury. Heated in a test-tube, it yields a red sublimate of vermilion. Ethiops mineral is a mixture of black amorphous mercuric sulphide, HgS, with a large excess of sulphur. Triturated with an equal weight of antimony sulphide, *æthiops antimonialis* is obtained. Pure black mercuric sulphide, HgS, is obtained by the action of hydrogen sulphide on mercuric salts.

Hydrargyri Sulphidum Rubrum. *Red mercuric sulphide, Cinnabar, Vermilion, Paris red*, E.; *Sulfure rouge de mercure*, Fr.; *Quecksilbersulfid, Zinnober*, G. HgS.—Cinnabar occurs in nature, and is the sole ore from which mercury is prepared. It is identical in composition with the black sulphide obtained by hydrogen sulphide, and occurs in crystalline or amorphous masses. Vermilion is manufactured on the large scale by subliming an appropriate mixture of mercury and sulphur. If the black mass obtained in the first part of this process is digested with solution of potassium hydroxide and potassium sulphide at a temperature of about 45° C. (113° F.), it will be gradually converted into vermilion. This is also produced by digesting white precipitate with a solution of sulphur in ammonium sulphide or of sodium thiosulphate. Sublimed mercuric sulphide forms brilliant dark-red crystalline masses having a fibrous fracture; after levigation it is seen in commerce in the form of a bright scarlet-red, fine, inodorous, and tasteless powder. It has the specific gravity 8.12, acquires a darker color on exposure to sunlight, but remains unaltered in the dark. When heated to above 250° C. (482° F.) it becomes brown, then black, and finally volatilizes, and assumes a red color again on cooling; heated in contact with the air, it burns with a blue flame, emitting the odor of sulphur dioxide. It is insoluble in water, alcohol, ether, hydrochloric or nitric or diluted sulphuric acid, cold concentrated sulphuric acid, or diluted alkaline solutions. Nitromuriatic acid dissolves it without heat, with the separation of sulphur and the production of sulphuric acid and mercuric chloride. It dissolves in boiling sulphuric acid, forming mercuric sulphate and separating sulphur; also in alkali sulphides containing potassa or soda. Metallic mercury is separated by heating vermilion with soda to redness; by boiling with water and iron or zinc; by zinc and warm diluted sulphuric acid, etc. Its complete volatility by heat insures the absence of red lead and basic lead chromate (American vermilion); and when it is treated with warm solution of potassium hydroxide the colorless solution, on being acidulated, should not yield a yellow or orange precipitate (absence of arsenic or antimony), nor should it produce a colored precipitate with lead acetate (absence of chromates, iodides, or other sulphides). If agitated with warm diluted nitric acid, it should not turn brown (absence of red lead), nor should the filtrate be colored or become dark-colored on the addition of hydrogen sulphide (lead) or of ammonia and ammonium sulphide (iron). Vermilion is seldom used in medicine, and then only by fumigation, the powder being thrown upon hot coals or iron. Vapors of mercury and sulphur dioxide are formed, the latter being very irritating and objectionable. This preparation is occasionally employed by fumigation. Because of the fact that sulphurous acid is present in the fumes, the irritating effect renders it an objectionable preparation.

Hydrargyri Tannas. *Hydrargyrum tannicum oxydulatum. Mercurous tannate*, E.; *Tannate de mercure*, Fr.; *Quecksilbertannat*, G.—Obtained by rubbing finely ground mercurous nitrate 50 parts, with 30 parts of tannin in 50 parts of water, until a uniform pasty mass is obtained, which is then rubbed up with 4–5 liters of water. The precipitate is filtered, washed with cold water, and dried at 30°–40° C. (86°–104° F.). It forms brown-green scales, odorless and tasteless, losing some tannic acid to water or alcohol. It contains about 43 per cent. of mercury. It is used in syphilis in pills, in the dose of from 1 to 2 grains (0.06–0.12 Gm.), 3 times a day.

Hydrargyri Thymolacetas. *Mercuric thymolacetate*, E.; *Thymolquecksilberacetat*, G.—Obtained by adding a warm alkaline thymol solution to a warm solution of mercuric acetate as long as the precipitate formed redissolves on shaking. The crystals formed on cooling are recrystallized from dilute sodium hydroxide. The salt is colorless, crystalline, difficultly soluble in water and alcohol, and contains 55 per cent. of mercury. Easily soluble in dilute alkalies, from which acids precipitate it unchanged. It is used by injection in syphilis, suspended in paraffin oil, in the dose of $\frac{1}{2}$ grain (0.01 Gm.), once a week.

Hydrargyrum Colloidale. *Colloidal mercury*, E.; *Colloïdales Quecksilber*, G. *Hyrgol.*—This is obtained by mixing very dilute solutions of stannous and mercurous nitrates containing a small quantity of nitric acid, salting out the colloidal mercury by adding a concentrated solution of ammonium citrate, and finally neutralizing with ammonia water. It occurs in dull-black porous pieces, forming a dark, neutral, non-corrosive solution with water, which turns silver-gray on heating as well as by addition of alkali or certain acids. Rubbed in a mortar it forms globules of mercury; hence if it is to be used in an ointment, it should be rubbed first with water.

According to Höhnel, colloidal mercury contains only 73–80 per cent. of mercury, the rest being tin salts, ammonium salts, nitric and citric acids in combination.

HYDRARGYRUM AMMONIATUM, *U. S., Br.*—Ammoniated Mercury.

Hydrargyrum præcipitatum album, P. G.; *Hydrargyrum amidato-bichloratum (ammoniato-muriaticum)*, *Hydrargyri ammonio-chloridum*, *Mercurius præcipitatus albus*.—*White precipitate*, *Mercuric ammonium chloride*, E.; *Chloramidure de mercure*, *Oxychlorure ammoniacal de mercure*, *Lait mercuriel*, *Mercure précipité blanc*, Fr.; *Weisser Quecksilberpräcipitat*, *Quecksilber-Chloridamid*, G.

Formula, NH_2HgCl. Molecular weight, 249.61.

It should contain not less than 78 per cent. nor more than 80 per cent. of metallic mercury.—U. S.

Preparation.—Corrosive mercuric chloride, 100 Gm.; ammonia water, distilled water, of each a sufficient quantity. Dissolve the corrosive mercuric chloride in 2000 Cc. of warm distilled water; filter the solution, and allow it to cool. Pour the filtrate gradually, while constantly stirring, into 150 Cc. of ammonia water, taking care that the latter shall remain in slight excess. Collect the precipitate upon a filter, and when the liquid has drained from it as much as possible wash it twice with a mixture of 400 Cc. of distilled water and 20 Cc. of ammonia water. Finally, dry the precipitate between sheets of bibulous paper in a dark place, at a temperature not exceeding 30° C. (86 F.). Keep in well-stoppered bottles, protected from light.—U. S.

The process of the German Pharmacopœia is in all respects identical with the foregoing, except that the washing of the precipitate is accomplished with distilled water instead of diluted ammonia. The process of the British Pharmacopœia is like the last, but a somewhat smaller quantity of ammonia is directed, and the precipitate is dried at a temperature not exceeding 100° C. (212° F.). The French Codex no longer recognizes this preparation; it should, however, be remembered that the *précipité blanc* of French pharmacy is *calomel* prepared by precipitation (see page 771).

The change in the above process consists in a replacement of half the chlorine in corrosive sublimate by the ammonia residue NH_2, known as the *amido* group, the remaining hydrogen atom forming hydrochloric acid with the displaced chlorine; thus, $HgCl_2 + NH_4OH = NH_2HgCl + HCl + H_2O$. The hydrochloric acid is neutralized by the excess of ammonia present. Another view of the constitution of the salt is that it is derived from ammonium chloride by replacement of two hydrogen atoms by a bivalent atom of mercury, as is suggested by the name mercuric ammonium chloride. The ammonium chloride formed in the preparation of the salt must be washed out, for which purpose the Pharmacopœia very properly uses a very dilute ammonia to prevent decomposition. If water be used, it should be cold, and the washing should not be continued too long, to prevent the precipitate from acquiring a yellowish tint in consequence of the formation of oxydimercur-ammonium chloride, $NH_2HgCl.HgO$. The above formula yields nearly 93 Gm. of ammoniated mercury.

Properties.—Ammoniated mercury is a white, amorphous, inodorous powder, or is often in friable masses, permanent in the air and having an earthy, afterward metallic taste. It is insoluble in ether, alcohol, and ammonia water; but is slowly decomposed by cold water, and yields with boiling water a lemon-yellow basic compound, $NH_2HgCl.HgO$, ammonium chloride being dissolved. When rapidly heated, it turns yellow, and above 360° C. (680° F.) is decomposed and completely volatilized without fusion, yielding nitrogen, ammonia, and calomel; when slowly heated, intermediate compounds are first formed. It is completely soluble in a cold solution of sodium thiosulphate, with evolution of ammonia; on digesting this solution for a short time it separates red mercuric sulphide, or vermilion, which on protracted boiling turns black.

Ammoniated mercury is decomposed by potassium hydroxide solution or lime water, ammonia being evolved and a yellow compound separated. It is soluble in hot solutions of ammonium salts and in hydrochloric as well as in nitric and acetic acids; these solutions yield white precipitates with potassium hydroxide (ammoniated mercury) and silver nitrate (silver chloride). When ammoniated mercury is triturated with iodine the mixture will after some time puff up, from the spontaneous decomposition of nitrogen iodide or iodamine formed in it, but in the presence of alcohol the decomposition takes place suddenly and with violent explosion.

Tests.—Ammoniated mercury should dissolve in hydrochloric acid without effervescence (absence of carbonate) and without residue (absence of mercurous salt, calcium sulphate, starch, etc.). 0.5 Gm., dissolved in 2 Cc. of hydrochloric acid and 25 Cc. of

water, should not respond to the tests for foreign salts, metals, or arsenic given under HYDRARGYRI CHLORIDUM CORROSIVUM.

Fusible white precipitate, which was formerly considered to be identical with the preceding, until Wöhler and Kane proved its difference, was prepared by dissolving ammonium and mercuric chlorides in water and precipitating with sodium carbonate. Thus obtained, it has the composition $(NH_3)_2HgCl_2$, or perhaps $NH_4Cl.NH_2HgCl$, and differs from the official ammoniated mercury in fusing to a yellowish liquid when heated, evolving nitrogen and ammonia and yielding a transparent and an opaque white sublimate.

Action and Uses.—Internally this drug acts as an irritant poison. It is used in an ointment externally in pustular acne and some chronic skin diseases.

HYDRARGYRUM CUM CRETA, *U. S., Br.*—Mercury with Chalk.

Æthiops cretaceus.—Gray powder, E.; *Mercure avec la craie, Poudre de mercure crayeux*, Fr.; *Quecksilber mit Kreide*, G.

Preparation.—Mercury, 38 Gm.; clarified honey, 10 Gm.; prepared chalk, 57 Gm.; water, a sufficient quantity to make 100 Gm. Weigh the mercury and clarified honey successively into a strong vial of the capacity of 100 Cc., and add 2 Cc. of water. Cork the vial, and shake it for 15 to 30 minutes at a time, until the aggregate time of shaking reaches 10 hours or until globules of mercury are no longer visible under a lens magnifying 4 diameters. Rub the precipitated chalk to a stiff paste, in a mortar, with water, and, having added the contents of the vial, washing the last portions in with a little water, triturating the whole to a uniform mixture. Finally, dry the mixture between ample layers of bibulous paper, at the ordinary temperature, until it weighs 100 Gm. Then reduce it to a uniform powder, without trituration, and keep it in well-stoppered bottles, protected from light.—U. S.

Take of mercury, by weight, 1 ounce; prepared chalk, 2 ounces. Rub the mercury and chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye and the mixture acquires a uniform gray color.—Br. P.

When certain substances are triturated with metallic mercury they acquire a gray tint, and the metallic luster of the mercury gradually disappears in consequence of its division (see HYDRARGYRUM). To effect this with chalk alone is a tedious operation. Dr. Squibb (1857) constructed an apparatus in which the mercury is shaken with honey or syrup, and when completely extinguished mixed with the chalk, most of the sugar being afterward washed out with cold water; this process yields a very pure product, but the globules are larger than in the products of the other processes, and the powder cannot be triturated with pressure without separating metallic globules. This plan of succession has been adopted by the pharmacopœia; it is probably better adapted for large manufacturers than the retail pharmacist.

In this state of fine division mercury is very prone to oxidation if exposed to air and light; hence the powder should be kept well protected from both. While traces of mercurous oxide cannot be entirely avoided, the presence of mercuric oxide should carefully be guarded against, and any change in color from gray to pink or reddish, indicating dangerous oxidation, renders the article unfit for use; neither should mercury with chalk be dispensed if the color has turned very dark-gray or blackish, as this shows excessive mercurous oxidation.

Properties and Tests.—Mercury with chalk is a gray, uniform, non-gritty, inodorous, and nearly tasteless powder, from which the mercury may be volatilized by heat. When treated with an excess of diluted acetic acid the chalk dissolves with effervescence, finely divided metallic mercury being left behind; the solution thus obtained should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide).—U. S. The presence of this oxide is disregarded by the British Pharmacopœia, which requires the preparation to be partly dissolved by dilute hydrochloric acid; any mercurous oxide present would be converted into calomel and remain with the finely divided, undissolved mercury; but it insists on the total absence of *mercuric oxide*, which is detected in the clear solution in hydrochloric acid by a white or gray precipitate with stannous chloride or by a black one with hydrogen sulphide. Arsenic may be detected in this solution in the same manner as in corrosive sublimate.

Action and Uses.—Mercury with chalk may be used for the same purpose as blue mass, but is much less active as a laxative and cholagogue. Indeed, in many instances

the constipating effect of the chalk prevents the mercury from moving the bowels at all. It is used in medicine chiefly in children with sluggish digestion, who also suffer from alternate attacks of constipation and fermentative diarrhœa. The dose for this purpose is usually from $\frac{1}{6}$ to $\frac{1}{2}$ grain (0.01–0.03 Gm.) every hour for 6 or 8 doses. Gray powder is also a useful mercurial for the purpose of treating infantile syphilis, as it does not irritate the stomach as do the preparations of mercury commonly used by adults suffering from this disease. In such cases it should, of course, be given continuously for a long time in doses varying from 1 to 5 grains (0.06–0.30 Gm.).

HYDRASTINA, *U. S.*—Hydrastine.

Hydrastine, Fr.; *Hydrastin*, G.

Formula, $C_{21}H_{21}NO_6$. Molecular weight, 380.32.

Hydrastine is the characteristic colorless alkaloid of *Hydrastis Canadensis*. It should be kept in well-stoppered bottles.—U. S.

The name hydrastine was first applied by Rafinesque in 1828 to the alkaloid now known as berberine, and was so continued by eclectic practitioners for many years. The eclectics were in the habit of using the hydrochloride of the alkaloid, which was known to them also as *muriate of hydrastine* and *neutral hydrastine*. At one time the terms *resinoid hydrastin* and *hydrastin, principles combined*, were applied to the precipitate obtained by pouring a concentrated alcoholic tincture of Hydrastis into cold water. This latter product is no longer on the market, but the terms *yellow hydrastine muriate* and *yellow hydrastine sulphate* are still used in some parts of the country, and invariably refer to the respective berberine salts. In 1850 A. B. Durand isolated the alkaloid now known as hydrastine (see *Am. Jour. Pharm.*, vol. xxiii. p. 13), but failed to obtain it free from yellow color, and it was first obtained white by J. D. Perrins, of England (*Pharm. Jour.*, May, 1862).

Preparation.—Hydrastine is prepared principally from the mother-liquors left after separation of the crystalline berberine sulphate, obtained by addition of a large excess of sulphuric acid to concentrated alcoholic or aqueous extracts of Hydrastis. The filtrate is treated with ammonia water and the resulting precipitate of crude hydrastine is purified by repeated solution and crystallization from alcohol or ethyl acetate. In case an alcoholic extract has been used, ammonia water is added until the liquid is nearly neutral, when the resulting deposit of ammonium sulphate is removed, the filtrate further concentrated and mixed with cold water to precipitate resinous and oily matter, and again filtered. Upon now adding an excess of ammonia water to the filtrate crude hydrastine is precipitated and then purified as stated above.

Properties.—Hydrastine occurs as colorless to white 4-sided prisms, which are odorless and quite tasteless, although the salts of hydrastine have a very bitter taste. It melts at 131° C. (267.8° F.) to a light amber-colored liquid, and is insoluble in petroleum ether. Hydrastine is almost insoluble in water at 25°C. (77° F.); soluble in 135 parts of alcohol, 124 parts of ether, and in 2 parts of chloroform at 25° C. (77° F.); soluble in 4000 parts of water at 80°C. (176° F.), and in 17 parts of alcohol at 60°C. (140°F.); easily soluble in benzene (U. S.). Hydrastine is lævorotatory, its specific rotation having been determined in chloroformic solution by F. B. Power as $[a]_D = -170°$ (*Proc. Am. Pharm. Assoc.*, 1884).

It dissolves in concentrated sulphuric acid with a faint-yellow color, changing to reddish purple on warming, or on the addition of manganese dioxide an orange-yellow color is developed which changes through cherry-red and carmine to a pale orange-yellow color. In sulphovanadic acid hydrastine dissolves with a rose-red tint, which fades slowly. Froehde's reagent produces a green color which gradually turns brown. Hydrastine mixed with 8 to 9 parts of morphine and dissolved in sulphuric acid produces a faint-yellow color, which after long standing develops into a purple, or if touched at once with a crystal of potassium dichromate (Lloyd) a play of colors is produced, of which the purple is the most conspicuous and quite permanent. In nitric acid hydrastine dissolves to an orange-colored solution, from which water precipitates an insoluble substance, while the supernatant liquid shows a strong blue fluorescence. A similar blue fluorescence is produced by chlorine in the aqueous solution of the hydrochloride (Mahla). A solution of hydrastine in dilute sulphuric acid instantly decolorizes potas-

sium permanganate solution, the liquid developing a deep-blue fluorescence (distinction from hydrastinine).

Hydrastine is precipitated amorphous from its aqueous solutions upon the addition of alkali hydroxides or carbonates, the precipitate gradually assuming a crystalline form. The salts of hydrastine yield precipitates with the alkaloidal reagents, platinic chloride producing an orange-yellow precipitate, gold chloride a yellowish-red precipitate, picric acid a yellow precipitate, potassium dichromate a yellow precipitate which instantly turns red when touched with sulphuric acid. Dilute solution of hydrastine added to a solution of iodine in potassium iodide yields a brown precipitate consisting of hydrastine hexa-iodide, which contains 60.40 per cent. of hydrastine (Prescott and Gordin, *Jour. Am. Chem. Soc.*, 21, pp. 732–741).

With oxidizing agents in acid solution hydrastine yields *hydrastinine* and *opianic* acid, while in alkaline solution hemipinic and narcotinic acids are produced.

The salts of hydrastine form more or less hygroscopic crystalline powders. They crystallize with difficulty. The hydrochloride and sulphate are preferred.

Action and Uses.—In toxic doses hydrastine increases reflex activity and produces muscular twitchings followed by tonic and clonic convulsions. At first there are a marked increase in the respiratory function, and a notable decrease followed by an increase in blood-pressure. Late in the poisoning there are decreased reflex activity, partial paralysis, and failure of respiration. Death usually results from respiratory paralysis, but may occur from cramp-asphyxia during a convulsion. This drug first stimulates and afterward depresses the motor side of the spinal cord. The sensory side of the cord, the motor and sensory nerves, and the muscles are also depressed after the administration of very full doses.

Hydrastine is usually employed for its local effect in the treatment of subacute and chronic inflammatory conditions of mucous membranes. It is especially useful in the form of an injection in treating gonorrhœa in males, vaginal gonorrhœa, leucorrhœa, and uterine catarrh. It may be employed internally in the treatment of gastro-intestinal catarrh and catarrhal jaundice, but is probably inferior to Hydrastis. The internal dose of pure hydrastine is from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.). The mixture of alkaloids termed impure hydrastine may be given in doses of from 3 to 10 grains (0.20–0.60 Gm.).

HYDRASTININÆ HYDROCHLORIDUM, *U. S.*—Hydrastinine Hydrochloride.

Hydrastininum hydrochloricum, P. G.; *Hydrastininhydrochlorid, Salzsaures Hydrastinin*, G.

Formula, $C_{11}H_{11}NO_2.HCl$. Molecular weight, 223.88.

The hydrochloride of an artificial alkaloid derived from hydrastine.

Preparation.—Schmidt and Wilhelm (1888) found that when hydrastine is treated with oxidizing agents in acid solution, hydrastinine and opianic acid are produced, the reaction being illustrated by the following equation: $C_{21}H_{21}NO_6$ (hydrastine) + O = $C_{11}H_{11}NO_2$ (hydrastinine) + $C_{10}H_{10}O_5$ (opianic acid). Dissolve 10 Gm. of hydrastine in 75 Cc. of nitric acid, specific gravity 1.20, and heat the solution to not over 60° C. (140° F.), until ammonia fails to produce a precipitate in a portion removed for testing. The solution is cooled and the opianic acid allowed to crystallize, after which the solution is filtered and the hydrastinine precipitated from the filtrate by adding an excess of potassium hydroxide solution. The precipitate is purified by recrystallization from benzene or acetic ether, and the crystals converted into the hydrochloride by dissolving them in concentrated hydrochloric acid and crystallization from alcohol.

Properties.—Hydrastinine hydrochloride forms light-yellow amorphous granules, or a pale-yellow crystalline deliquescent powder. It is odorless, and possesses a bitter, saline taste. It is very soluble in cold and hot water and in alcohol; soluble in 286 parts of chloroform and 1300 parts of ether at 25° C. (77° F.), U. S. When heated to 173° C. (343.4° F.) the salt undergoes partial fusion, but does not liquefy; on ignition it is wholly consumed. It fuses at 212° C. (413.6° F.), U. S., near 210° C. (410° F.), P. G. "The aqueous solution, especially when highly diluted, shows a blue fluorescence and is neutral to litmus-paper. On ignition it should be perfectly consumed. In an aqueous solution of the salt (1 in 20) bromine test-solution produces a yellow precipitate, which should be perfectly soluble in ammonia-water, forming an almost

colorless solution. In an aqueous solution of the salt, potassium dichromate test-solution produces a precipitate which redissolves if gently heated, but on cooling the solution it separates in glistening needles. If ammonia-water be added to an aqueous solution of hydrastinine hydrochloride (1 in 20), no turbidity should be produced. On slowly adding to a solution of 0.19 Gm. of the salt in 3 Cc. of water 4 to 5 drops of a solution of sodium hydroxide (1 in 7), each drop will cause a milky turbidity, which disappears again on shaking. From this solution, after standing for some time, pure white hydrastinine should separate, and the supernatant fluid should be almost colorless. With a crystal of the salt, sulphuric acid or nitric acid produces a deep-yellow color; sulphuric acid with a trace of nitric acid, a reddish-brown color; sulphuric acid with a crystal of ammonium vanadate, a light-brown color changing to dark brown."—U. S.

Action and Uses.—This artificial alkaloid is said to increase the force of the cardiac contractions, to decrease the rapidity of the heart's action by stimulating the vagus, and to increase blood-pressure by its action on the bloodvessels. It is a depressant to the motor side of the cord, causing complete paralysis when given in sufficient amount. It has been recommended for the control of uterine hemorrhages, and is said to be a very efficient oxytoxic. The dose hypodermically is from $\frac{1}{2}$ to 1 grain (0.03–0.05 Gm.).

HYDRASTIS, *U. S.*—Hydrastis.

Golden seal, Yellow root, Yellow puccoon, Orange-root, Indian dye, Indian turmeric, Yellow eye, Jaundice-root, E.; *Racine orange, Sceau d'or,* Fr.; *Canadische Gelbwurzel, Gelbes Blutkraut,* G.; *Rizoma di Idraste,* It.; *Raizamarilla sello de oro,* Sp.

The dried rhizome of *Hydrastis Canadensis* L. (*Warnera C.* Mill.—Fam. *Ranunculaceæ*), yielding, when assayed by the U. S. P. process, not less than 2.5 per cent. of hydrastine.

Hydrastis is official in most pharmacopœias, several of which refer to its yellowing the saliva when masticated.

Origin.—A low perennial of rich woodlands in the eastern United States, especially in the Ohio valley, and rapidly becoming scarcer. It bears above 2 roundish, heart-shaped, palmately lobed leaves, and a single greenish-white flower, consisting of 3 caducous petal-like sepals, numerous stamens, and about a dozen or more pistils, each becoming in fruit a scarlet 1- to 2-seeded berry. Lloyd has shown that the rhizome is much richer in alkaloid than the roots.

FIG. 219.

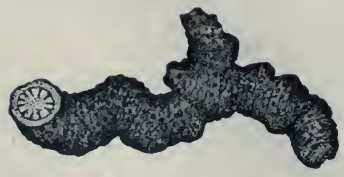


FIG. 220.

Hydrastis (Nat.).

FIG. 221.

Hydrastis (½ Nat.).

Description.—Of oblique growth, 2.5 to nearly 5 Cm. (1 to nearly 2 In.) long and 0.5 to 1 Cm. ($\frac{1}{5}$ to $\frac{2}{5}$ In.) thick, cylindraceous, usually with a few short branches, longitudinally wrinkled, but plump, somewhat annulate, externally brownish-gray, often with a yellow

tinge or yellowish patches; fracture short and sharp, waxy, golden-yellow or bright reddish yellow, with a thickish bark, about 10 short and narrow wood-wedges and broad medullary rays; roots, if present, rather coarse, brittle, with a thick bark and somewhat quadrangular wood; odor slight, characteristic; taste very bitter, but not disagreeable, producing a somewhat astringent effect.

The powder, except under chemical treatment, shows little that is characteristic. There should be no crystals present, and the starch-grains are almost invariably single, presenting a nearly circular outline, with indistinct rings and central hilum, and are mostly 5 to 10 mikrons in breadth.

As adulterants of Hydrastis, Cypripedium, Stylophorum, Serpentaria, Asarum, and various other rhizomes have been reported, but none of them, nor indeed any other article known to us, can be reasonably mistaken for it, in the entire condition. All others presenting a like bright-yellow color have a tough or splintery fracture and a distinct form. Several pharmacopœias specify that in a 1 per cent. infusion mixed with a half volume of sulphuric acid, and a few drops of chlorine water (or bromine water) poured upon it, a dark-red layer will be observed; also that small yellow crystals will separate a few hours after $\frac{1}{10}$ volume of nitric acid has been added to a 10 per cent. infusion. The most important adulteration is an undue amount of earthy matter, resulting from imperfect cleansing. This is indicated by an increase in the ash.

Constituents.—Besides fixed oil, starch, gum, sugar, yellow coloring-matter, etc., hydrastis yields 2 to 3 per cent. of the alkaloid hydrastine (see HYDRASTINA), 3 to 4 per cent. of berberine, and some canadine. The ash is about 5 per cent. Hydrastis probably contains also a volatile odorous principle, and at least one other alkaloid.

Berberine, $C_{20}H_{17}NO_4$, was first obtained by Hüttenschmid (1824) from the Jamaica cabbage tree (*Geoffroya inermis*), and named by him *jamaicine*. In 1828 it was found by Rafinesque in Hydrastis, and called hydrastine. It occurs in a number of other plants, such as Berberis (from which it takes its name), Xanthorriza, Coptis, etc., but according to H. M. Gordin is not present in Calumba, Pareira, Menispermum, and Jeffersonia, which were formerly supposed to contain the alkaloid. It may be obtained from hydrastis, or any other drug containing it, by boiling the same with water acidulated with acetic acid. The decoction is filtered, evaporated to a syrupy liquid, and mixed with 3 times its volume of diluted sulphuric acid (1 in 5). The resulting yellow needle-shaped crystals of berberine acid sulphate, $C_{20}H_{17}NO_4H_2SO_4$, are washed with cold water, dissolved in boiling water, and, after addition of alcohol and some sulphuric acid, again allowed to crystallize. From this purified salt the alkaloid may be liberated by treating a warm aqueous solution with baryta water in slight excess, filtering, passing carbon dioxide into the filtrate, again filtering, and concentrating the solution, which is then allowed to crystallize. Or a solution of berberine acid sulphate is mixed with acetone and then rendered alkaline by addition of sodium hydroxide solution, when berberine-acetone, $C_{20}H_{17}NO_4.C_3H_6O$, is formed, which separates in form of pale-yellow needles, and, being insoluble in water, may be freed from adhering impurities by washing with water. This berberine-acetone, when boiled with a mixture of alcohol and chloroform for 10 or 12 hours in a flask provided with a reflux condenser, yields pure berberine, which may be obtained by concentrating the solution and crystallizing, and afterward purifying by recrystallization from water. Berberine occurs in form of odorless, shining, yellowish-brown needles, having a neutral reaction and a bitter taste. If crystallized from water, it contains 6 molecules of water, of which 4 are lost if the crystals are heated to 100° C. (212° F.). It is readily soluble in boiling water or alcohol, but far less soluble in these liquids when cold, and is practically insoluble in ether, benzene, ethyl acetate, ligroin, carbon disulphide, and benzin. Berberine melts at about 140° C. (284° F.). Besides the berberine-acetone mentioned above, freshly precipitated berberine is capable of forming compounds with alcohol, chloroform, bromoform, and other bodies. When boiled with chloroform, berberine decomposes the same, forming berberine hydrochloride.

The salts of berberine are less soluble in water than the alkaloid, and may be obtained by adding the respective acid in excess to a hot aqueous solution of berberine and allowing the mixture to cool.

For estimating berberine in liquids containing much other matter, it is best to precipitate it as an insoluble hydroiodide, washing this thoroughly with weak potassium iodide solution and converting the salt into crystalline berberine-acetone. (For details of the process see *Proc. Am. Pharm. Assoc.*, 1901, pp. 238–245.)

Canadine (xanthopuccine), $C_{20}H_{21}NO_4$, which according to E. Schmidt is tetrahydroberberine, forms white acicular crystals or small white warty nodules, insoluble in water, and soluble in alcohol, ether, chloroform, and benzene. It melts at 132°–133° C. (269.6°–271.4° F.). The isolation of canadine free from color is a tedious operation, requiring

repeated precipitation. Exposed to light, canadine gradually becomes yellow, changing to berberine. The nitrate, hydrochloride, and hydrobromide are difficultly soluble in water, especially if an excess of acid be present. Canadine sulphate, however, is readily soluble in water. Upon heating canadine to 100° C. (212° F.) with alcoholic solution of iodine, it is converted into berberine hydroiodide.

Assay of Hydrastis.—The value of hydrastis lies in the amount of hydrastine present, and of this alkaloid the U. S. P. demands the presence of not less than 2.5 per cent. in the drug, which may be determined as follows: Into a 250 Cc. flask put 15 Gm. of hydrastis in No. 60 powder; add 150 Cc. of ether, shake the flask during 10 minutes, and add 5 Cc. of 10 per cent. ammonia water, shaking the flask frequently during a half hour. Then add 15 Cc. of distilled water and shake until the drug collects in masses, and at once carefully decant 100 Cc. of the ethereal fluid, representing 10 Gm. of the drug, into a measuring-cylinder and transfer the same to a separator, rinsing the cylinder with a little ether. To the contents of the separator add 20 Cc. of normal sulphuric acid, shake moderately, and allow the liquids to separate. Draw off the lower acid solution into another separator, and to the contents of the first separator add 5 Cc. more of normal acid and 5 Cc. of distilled water and shake. After complete separation, again draw off the lower liquid into the second separator. Wash the contents of the first separator with 5 Cc. of distilled water, and after separation draw this also off into the second separator. Introduce a small piece of red litmus paper into the second separator, add 25 Cc. of ether and an excess of ammonia-water, shake moderately for a few minutes and allow the liquids to separate, after which draw the lower aqueous fluid carefully into a clean separator, and pour the upper ethereal solution into a tared Erlenmeyer flask or beaker. Shake out the alkaline aqueous fluid twice more with ether, using 20 Cc. each time, and proceed as before, adding the ethereal solutions to the contents of the beaker or flask. Evaporate or distil off the ether carefully on a water-bath and dry the alkaloidal residue to constant weight at 100° C. (212° F.). The weight of dry residue found multiplied by 10 gives the percentage of hydrastine in the drug.

Pharmaceutical Preparations.—Fluidextract of Hydrastis, Glycerite of Hydrastis, Tincture of Hydrastis, U. S. P.

Action and Uses.—In medicinal amounts hydrastis has little effect upon the vital functions, but in large amounts is exceedingly poisonous. Its activity is largely due to the hydrastine which is present, and if this be injected into the circulation, an immediate fall of blood-pressure, followed afterward by a rise, occurs. This rise is probably due to contraction of the peripheral capillaries. Upon the nervous system it at first acts as an excitant, causing an increase in reflex activity, followed by muscular twitchings, tetanic convulsions, complete paralysis, and death from respiratory failure. In moderate amounts it is said to possess oxytoxic properties, producing contractions in the non-pregnant uterus and abortion in the pregnant uterus of lower animals. Hydrastis is quite largely employed in the treatment of depraved mucous membranes, as, for example, in chronic rhinitis, the atonic stomach of drunkards, chronic intestinal catarrh, catarrhal jaundice, vaginal leucorrhœa, and the later stages of gonorrhœa. It has been recommended also in the treatment of uterine hemorrhages resulting from endometritis, such as menorrhagia, and metrorrhagia, and is said to act well in those cases in which ergot has proved useless. The dose of the fluidextract is from 5 to 10 minims (0.30–0.60 Cc.); of the tincture, from ½ to 2 fluidrachms (2–8 Cc.). Pure hydrastine is employed in doses of from ¼ to ½ grain (0.015–0.03 Gm.). The impure variety of hydrastine containing berberine may be given in doses of from 3 to 10 grains (0.20–0.60 Gm.).

HYOSCINÆ HYDROBROMIDUM, *U. S., Br.*—Hyoscine Hydrobromide.

Scopolaminum Hydrobromicum, P. G.; *Hyoscinum Hydrobromicum.—Scopolamine hydrobromide*, E.; *Bromhydrate d'hyoscine*, Fr.; *Skopolaminhydrobromid, Hyoscinhydrobromid, Bromwasserstoffsaures Hyoscin*, G.

Formula, $C_{17}H_{21}NO_4.HBr + 3H_2O$. Molecular weight, 434.92.

The hydrobromide of an alkaloid identical with scopolamine, obtained from hyoscyamus and other plants of the *Solanaceæ*. It should be kept in well-stoppered, amber-colored vials.—U. S.

The name hyoscine was first applied by Ladenburg in 1880 to an alkaloid obtained by him from the mother-liquors remaining in the manufacture of hyoscyamine and having the composition $C_{17}H_{23}NO_3$. It was also found in the leaves of *Duboisia myoporoides* by the same investigator. Later, in 1890, E. Schmidt obtained from *Scopola Japonica* and *Scopola atropoides* an alkaloid having the composition $C_{17}H_{21}NO_4$, to which he gave the name scopolamine and which was later proved to be identical with hyoscine. Schmidt

also obtained this alkaloid from the root of *Belladonna*, the seed of *Stramonium*, and the leaves of *Duboisia*. Since the true composition of this alkaloid, as now recognized in all pharmacopœias, is associated with the name given it by Schmidt, it would seem but proper also to apply the name given by him, but this has been done only in the German Pharmacopœia, although the British gives scopolamine as a synonym, and the U. S. declares the two alkaloids to be identical. Commercially, the name hyoscine is better known than scopolamine.

Preparation.—Hyoscine or scopolamine hydrobromide is obtained chiefly from the seed of hyoscyamus and stramonium, either by neutralizing the mother-liquors remaining, after removal of hyoscyamine, with hydrobromic acid and adding absolute alcohol, when after the lapse of some time crystals of hyoscine hydrobromide will separate and may be purified by recrystallization from hot alcohol, or by neutralizing the mother-liquors with hydrochloric acid, diluting the solution with water, and then precipitating the alkaloid in the form of a double chloride by addition of gold chloride solution. By recrystallization the double chloride of alkaloid and gold is finally obtained pure, having a constant melting-point of 198° to 199° C., from which, by treatment with hydrogen sulphide, the gold may be removed and the alkaloid, after subsequent liberation by means of potassium carbonate, be shaken out with chloroform and obtained in the form of a tough, syrupy residue by evaporation of the solvent. It is then dissolved in ether and allowed to crystallize. The crystals or the syrupy residue mentioned above are dissolved in sufficient diluted hydrobromic acid to produce a neutral solution, from which, by slow evaporation, crystals of hyoscine hydrobromide are obtained.

Properties and Tests.—"Colorless, transparent, rhombic crystals, sometimes of large size, odorless, having an acrid, slightly bitter taste; slightly efflorescent in dry air. Soluble in 1.5 parts of water, in 16 parts of alcohol, and in 750 parts of chloroform at 25° C. (77° F.); soluble in 1.33 parts of alcohol at 60° C. (140° F.); insoluble in ether. Hyoscine hydrobromide, when heated, softens at about 100° C. (212° F.); it first melts and then loses its water of crystallization at 110° C. (230° F.). If dried over sulphuric acid until its water of crystallization is lost, it then melts at 179.7° C. (355.5° F.). When ignited it leaves no residue. Hyoscine chloraurate crystallizes in yellow prisms and melts at 197° C. (386.6° F.). Hyoscyamine chloraurate crystallizes in yellow leaflets and melts at 160° C. (320° F.). Atropine chloraurate crystallizes in dull yellow grains and melts at 136° C. (276.8° F.).) Its aqueous solution shows a slightly acid reaction to blue litmus-paper. If 2 Cc. of chloroform be shaken with 1 Cc. of a solution of hyoscine hydrobromide (1 in 10), to which a few drops of chlorine water have been cautiously added, it should assume a brownish color. If 0.01 Gm. of the salt be added to 5 drops of nitric acid and evaporated to dryness in a porcelain dish, it should yield a violet color upon the addition of alcoholic potassium hydroxide test-solution. Silver nitrate test-solution, when added to solutions of the salt, affords a yellowish-white precipitate insoluble in nitric acid, but the washed precipitate is soluble in an excess of ammonia-water. Mercuric potassium iodide test-solution, in aqueous solutions of the salt acidified with hydrochloric acid, yields a yellowish-white precipitate. Mercuric chloride test-solution and solution of phosphotungstic acid give a white precipitate in aqueous solutions of the salt. Picric acid test-solution and platinic chloride test-solution yield a yellow precipitate when added to concentrated solutions of the salt. Sulphuric acid should give no color when added to hyoscine hydrobromide (absence of carbonizable impurities); nor should any color be developed on the subsequent addition of a drop of nitric acid (absence of morphine)."—U. S.

The British Pharmacopœia gives the solubility of the salt as 1 part in 1 part of water and in 13 parts of 90 per cent. alcohol at 15.5° C. (60° F.), and states the melting-point of the hyoscine aurochlorate to be 198° C. (388.4° F.).

Action and Uses.—In certain cases of great nervous excitement hyoscine produces the most happy results, acting as a soporific, quieting the disturbed nervous system, and at times producing deep sleep lasting from 6 to 8 hours. It is, however, quite uncertain, at times producing delirium, and respiratory and circulatory depression. The drug is said to be especially advantageous in those cases in which an idiosyncrasy to morphine exists, or in which renal or other organic changes contraindicate the latter remedy. If given in full dose, it acts as a depressant to the respiratory center and the spinal cord, decreasing respiration and reflex action. As a rule, little or no change is noted in the circulation, even when it is given in poisonous amounts. Full doses produce flushing of

the face, drowsiness or delirium, and dryness of the mouth. Excessive amounts cause an exaggeration of the above symptoms, with Cheyne-Stokes respiration, muscular relaxation, a peculiar hoarseness of the voice, and dilated pupils. Profound stupor lasting a number of hours may also occur. This condition is to be treated by the administration of pilocarpine and suitable stimulants as required.

Hyoscine has been employed in the treatment of acute mania, during exacerbations occurring in chronic mania, and as a cure for the morphine-habit. It has also been successfully employed in the treatment of nymphomania, hypochondriasis, spermatorrhœa, and nocturnal emissions.

The drug may be given by the mouth or hypodermically in doses varying from $\frac{1}{150}$ to $\frac{1}{100}$ grain (0.0004–0.0006 Gm.).

HYOSCYAMINA, *Fr. Cod.*—Hyoscyamine.

Hyoscyamine, Fr.; *Hyoscyamin*, G.

Formula, $C_{17}H_{23}NO_3$. Molecular weight, 287.04.

The alkaloid hyoscyamine occurs not only in hyoscyamus, but also in belladonna, stramonium, and other solanaceous plants, and is an isomer of atropine, into which it is readily converted. It was discovered by Geiger and Hesse in 1833, and is recognized in the French Pharmacopœia.

Preparation.—Hyoscyamine is so readily altered by contact with alkalies and heat that all manipulation and heating should be reduced to a minimum during its isolation. It may be obtained from henbane seed or recovered from the mother-liquors left in the preparation of atropine. The process of Thorey tends to the least alteration of the alkaloid during its extraction. Hyoscyamus seeds are freed from fatty matter by repeated extraction with petroleum-ether and after drying are exhausted with 85 per cent. alcohol and acidulated with hydrochloric acid. The tincture, after removal of the alcohol in a vacuum apparatus, is filtered, and the filtrate again treated with petroleum-ether to remove fatty and coloring-matter, after which it is made alkaline with ammonia (potassium carbonate is to be preferred), and shaken with repeated portions of chloroform. Upon evaporation of the chloroformic solution at low temperature the hyoscyamine is obtained as a gummy residue, and may be purified by solution in dilute sulphuric acid, filtering, and crystallizing. From the sulphate thus obtained, the alkaloid is liberated by rendering an aqueous solution alkaline, extracting with chloroform, and evaporating the latter solution at a low temperature.

Properties.—Hyoscyamine crystallizes in the form of anhydrous slender, silky needles, which are colorless, odorless, have an acrid, disagreeable taste, and melt at 108.5° C. (227.3° F.). The commercial article is usually amorphous. Hyoscyamine is soluble to some extent in water, more readily in diluted alcohol, and is soluble in alcohol, ether, chloroform, benzene, and amyl alcohol. It dissolves in concentrated sulphuric acid without color. From its solution in chloroform it crystallizes in rhombic plates, and from benzene in the form of needle-shaped crystals. Hyoscyamine is but incompletely precipitated from aqueous solutions of its salts by alkali hydroxides and carbonates. In aqueous solution by itself or in contact with alkalies it undergoes change into atropine, and like the latter undergoes hydrolysis into tropine and tropic acid (Ladenburg). In its general behavior toward alkaloidal reagents it acts like atropine, with but few exceptions, but is strongly lævorotatory, while atropine is optically inactive. Until recently only one optically active hyoscyamine was known, although the existence of a dextrorotatory variety was strongly suspected. The exact relation between atropine and hyoscyamine was revealed by Amenomiya (*Arch. d. Pharm.*, 1902, 240, p. 498), who succeeded in converting the former alkaloid into d- and l-hyoscyamine. By boiling pure atropine with water for some time (24 to 27 hours) under a reflux condenser, it was split into tropine and optically inactive tropic acid, which latter was then neutralized with quinine alkaloid. Upon concentrating a solution of the quinine tropate thus formed, a dextrorotatory salt crystallized out, leaving a lævorotatory compound in the mother-liquors, from which it was subsequently separated upon further concentration. The two salts were decomposed with stronger acids, when the respective d- and l-tropic acids were liberated and then mixed with a nearly equal quantity of tropine, 1.69 Gm. of tropine and 2 Gm. of the respective acid, and 50–70 Cc. of 5 per cent. hydrochloric acid, the mixtures being evaporated to a volume of 5–7

Cc. on a water-bath, whereby the hydrochlorides of the respective new bases were obtained. Rendering the solutions alkaline and shaking out repeatedly with ether, yielded the respective crude bases, which were purified by conversion into aurochlorides, subsequent decomposition by means of hydrogen sulphide, and final crystallization. The synthetic dextro-hyoscyamine thus obtained showed a specific rotation of + 23.15° and the lævo-hyoscyamine of − 24.12°, while natural hyoscyamine has a specific rotation of —21.8°. Hyoscyamine shows an alkaline reaction with phenolphtalein, and causes a yellow to red precipitate when touched with a 2 per cent. solution of mercuric chloride in diluted alcohol (Gerrard). In 5 per cent. solution platinic chloride produces no precipitate, but on evaporation triclinic crystals, melting at 200° C. (393° F.), are formed. Gold chloride produces a precipitate which forms lustrous golden-yellow scales which melt at 160°–162° C. (320°–323.6° F.). Picric acid causes a precipitate of yellow needle-shaped crystals, melting at about 162° C. (321.8° F.).

The alkaloid *pseudohyoscyamine*, $C_{17}H_{23}NO_3$, has been found in *Duboisia myoporoides*, associated with hyoscyamine. It differs from hyoscyamine in crystallizing in yellow needles which melt at 133°–134° C. (271.4°–273.2° F.), and being difficultly soluble in water and ether, although readily soluble in alcohol and chloroform. It is readily hydrolized by boiling with alkalies in alcoholic solution, yielding tropic acid and a base isomeric with tropine. Aside from its higher melting-point, pseudohyoscyamine may be distinguished from hyoscyamine by forming with platinic chloride a precipitate melting at 116° C. (240.8° F.), with gold chloride thin yellow plates melting at 176° C. (348.8° F.), and with picric acid yellow needles melting at 220° C. (428° F.).

Action and Uses.—The properties and uses of this alkaloid are practically the same as those of HYOSCYAMINÆ SULPHAS (which see).

HYOSCYAMINÆ HYDROBROMIDUM, *U. S.*—Hyoscyamine Hydrobromide.

Hyoscyaminum hydrobromicum.—Bromhydrate d' hyoscyamine, Fr.; *Hyoscyaminhydrobromid, Bromwasserstoffsaures Hyoscyamin*, G.

Formula, $C_{17}H_{23}NO_3HBr$. Molecular weight, 367.40.

The hydrobromide of an alkaloid obtained from *Hyoscyamus* and other solanaceous plants. It should be kept in amber-colored, well-stoppered bottles.—U. S.

Preparation.—Hyoscyamine hydrobromide may be prepared by dissolving 10 parts of hyoscyamine in 11 parts of 25 per cent. hydrobromic acid, evaporating the solution, and crystallizing.

Properties and Tests.—"White, prismatic crystals, or a yellowish, amorphous, resin-like mass, having, particularly when damp, a tobacco-like odor and an acrid, nauseous, and bitter taste; deliquescent on exposure to the air. Very soluble in water, in 2 parts of alcohol, in 1600 parts of ether, and in 2.5 parts of chloroform at 25° C. (77° F.). It melts at 151.8° C. (305.3° F.). It leaves no residue on incineration. Hyoscyamine chloraurate melts at 160° C. (320° F.). Atropine chloraurate melts at 136° C. (276.8° F.). Hyoscine chloraurate melts at 197° C. (386.6° F.). Hyosoyamine picrate melts at 162° C. (323.6° F.). Atropine picrate melts at 175° C. (347° F.). Its aqueous solution is neutral to litmus-paper and is strongly lævogyrate. Silver nitrate test-solution, when added to a solution of the salt, yields a yellowish-white precipitate which is insoluble in nitric acid, but the washed precipitate is soluble in ammonia water. Gold chloride test-solution, when added to a solution of the salt, yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited on cooling in minute, lustrous, golden-yellow scales (difference from atropine). Platinic chloride test-solution does not form a precipitate with solutions of the salt (difference from most alkaloids). If 0.01 Gm. of the salt be added to 5 drops of nitric acid, then, on evaporation to dryness in a porcelain dish, it should yield a violet color upon the addition of alcoholic potassium hydroxide test-solution. Sulphuric acid should produce no color when added to hyoscyamine hydrobromide (absence of carbonizable impurities), nor should any color be developed upon the subsequent addition of a drop of nitric acid (absence of morphine)."—U. S.

Action and Uses.—The action and uses of this salt are identical with those of hyoscyamine sulphate.

HYOSCYAMINÆ SULPHAS, *U. S., Br.*—Hyoscyamine Sulphate.

Hyoscyaminum sulfuricum.—Sulfate d'hyoscyamine, Fr. ; *Hyoscyaminsulfat, Schwefelsaures Hyoscyamin*, G.

Formula, $(C_{17}H_{23}NO_3)_2H_2SO_4$, U. S. ; $(C_{17}H_{23}NO_3)_2H_2SO_4 + 2H_2O$, Br. Molecular weight, 671.43, or for the British salt 707.19.

The neutral sulphate of an alkaloid obtained from *Hyoscyamus* and other solanaceous plants. It should be kept in amber-colored, well-stoppered bottles.—U. S.

Preparation.—Hyoscyamine may be dissolved in alcohol and the solution carefully neutralized with diluted sulphuric acid and evaporated at a low temperature ; or a solution of the alkaloid in diluted sulphuric acid may be concentrated under a bell-glass over sulphuric acid.

Properties and Tests.—"White, indistinct crystals, or a white powder, odorless, having a bitter, acrid taste ; deliquescent in damp air. Very soluble in water, in 6.4 parts of alcohol, 2500 parts of ether, and in 2300 parts of chloroform at 25° C. (77° F.). It melts at 198.9° C. (390° F.). Upon ignition it is rapidly consumed without residue. Hyoscyamine chloraurate melts at 160° C. (320° F.). Atropine chloraurate melts at 136° C. (276.8° F.). Hyoscine chloraurate melts at 197° C. (386.6° F.)). Its aqueous solution is lævogyrate and neutral to litmus-paper. Barium chloride test-solution, when added to an aqueous solution, yields a white precipitate, insoluble in hydrochloric acid. Gold chloride test-solution, when added to an aqueous solution, yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited on cooling in minute, lustrous, golden-yellow scales (difference from atropine). Platinic chloride test-solution does not form a precipitate with solutions of the salt (difference from most alkaloids). If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should yield a violet color upon the addition of alcoholic potassium hydroxide test-solution. Sulphuric acid should produce no color when added to hyoscyamine sulphate (absence of carbonizable impurities), nor should any color be developed upon the subsequent addition of a drop of nitric acid (absence of morphine)."—U. S.

Action and Uses.—This salt apparently has the same physiological action upon the vital functions as atropine (which see), with the exception of the respiratory function. It is stated by some and denied by others that the drug slows the respiration, but this may be easily accounted for from the fact that an impure product may have been employed. Its effect as a mydriatic, in the strength of 2 grains (0.12 Gm.) to 1 ounce (30 Cc.) of distilled water, is not so lasting as that of atropine, continuing, as a rule, from 7 to 9 days. When a solution of hyoscyamine sulphate is first instilled, it may cause considerable pain, due to spasm of the ciliary muscle, which pain may be relieved by pushing the drug until muscular relaxation occurs. The beginning internal dose is $\frac{1}{75}$ grain (0.0008 Gm.), which may be gradually increased if necessary. (See HYOSCYAMUS.)

HYOSCYAMUS, *U. S.*—Hyoscyamus.

Hyoscyami folia, Br. ; *Herba hyoscyami*, P. G. ; *Henbane, Black henbane, Stinking nightshade, Insane root, Poison tobacco ; Belene, Chenile, Jusquiame noir*, Fr. Cod. ; *Bilsenkraut*, G. ; *Beleno negro*, Sp. ; *Meimendro Negro*, Port. ; *Giusquiamo Nero*, It.

The dried leaves and flowering tops of *Hyoscyamus niger* L. (Fam. *Solanaceæ*) collected from plants of the second year's growth, yielding, when assayed by the U. S. P. process, not less than 0.08 per cent. of mydriatic alkaloids. (*H. agrestis* Kit. and *H. pallidus* Willd. are forms of the above.)

The presence of the flowers, required by this definition, excludes the use of the biennial plant in the first year of its growth, as it does not then flower. The presence of small purple veins in the corollas, as required by the description, renders it reasonably certain that they do not pertain to the annual plant.

Henbane is official in all pharmacopœias, most of which require the leaves only. Some require that it be collected from uncultivated plants, others that it be not used after keeping for more than a year.

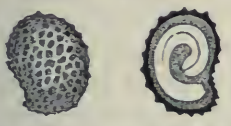
Origin.—The Henbane plant is a native of central and southern Europe and adjacent Asia, occurring even as far east as India. It is considerably cultivated for medicinal purposes, in various European countries. It is more or less naturalized

in nearly all temperate regions, including the United States. It presents two distinct forms. The first is an annual, and concerns us only as to its exclusion, in accordance with the definition. It seldom exceeds 2 feet in height, is slender, and little if at all branched. All its parts are smaller, its leaves are less strongly toothed, and its corollas faintly or not all veined with purple. The other is the biennial form, which, during the first year, develops a large fleshy, fusiform root, somewhat resembling a small horse-radish, and a radical rosette of very large leaves with very long petioles, the blades coarsely toothed, lobed, or sub-pinnatifid. During the second year, the flowering and fruiting stem is produced, after which the plant dies. In this stage the root becomes spongy, then hollow, the radical leaves are wanting, those of the stem being relatively broader and with shorter petioles, these modifications increasing toward the summit of the stem, where the leaves are sessile. The stem is thick and coarse, widely branched, and from 3 to 5 feet high. The inflorescence characters are shown in the accompanying illustration. The whole plant is clammy or viscid, due to numerous hairs with glandular tips. The corallas of this form are deeply purple-veined. The commercial drug presents varieties representing all three of these stages, and these are distinguished by the trade-names "Annual," "First-biennial" (for leaves from the biennial in its first year), and "Biennial" or "Second Biennial" for that described in our definition. The latter is scarce and high-priced.

FIG. 222.

Hyoscyamus niger L.

FIG. 223.



Hyoscyamus seed and longitudinal section (× 7).

Statements of the most positive character differ radically as to the relative quality of the drug as grown in different regions, on different soils, and collected in the three stages named above. The discrepancies are apparently due in part to different methods of estimation, and in part to differences in the articles compared other than those under consideration at the time. Evidently a great number of comparisons must yet be made before these points can be regarded as settled, and the observations must begin with the collection of the materials so as to guarantee the absolute identity of all the conditions and characters except the one under investigation. There is a general belief that the annual drug and the first biennial are very inferior, though Gerrard's results showed no differences in alkaloidal content. He also found the biennial root at the close of the first year to be nearly 3 times as rich as any of the herbs examined, a report which appears *a priori* most rational. He carried his comparisons into clinical results with the preparations, these appearing to confirm those of his assay methods.

Description.—Coarsely, roughly and glandularly hairy throughout, except the corollas; larger leaves shortly and broadly petioled, 15 to 25 Cm. (6 to 10 In.) long, and two-thirds as broad, the upper becoming smaller and sessile; blades angularly ovate, acute, coarsely and angularly toothed or lobed, grayish-green or slightly yellowish-green; flowers in pseudo-racemes, short-pedicelled, the calyx cylindraceous, somewhat contracted above the ovary, unequally 5-toothed, the teeth triangular, acute, the corolla campanulate, 5-lobed, sulphur-yellow, with deep-purple veins; capsule a 2-celled pyxis; odor heavy, narcotic; taste bitter, somewhat acrid. The powdered leaf displays numerous oblong prismatic crystals of calcium oxalate, almost invariably occurring singly in their cells. Besides the simple hairs, there are many which are glandular, and these may terminate in a single cell, or in a head of many cells regularly or irregularly arranged.

Usher points out that the annual drug (as to the British-grown plant) lacks odor and taste sufficiently to lead at once to its recognition. Its leaves are shorter and its flowers, though frequently having light-purple veins, sometimes show none, which is never true of the biennial. The first biennial drug is entirely wanting in flowers and stems, except the leaf-petioles, which are very long, stout, and conspicuous.

Henbane, except for the use of the above-described unofficial forms, is scarcely subject to adulteration in the entire condition. It, however, frequently contains an undue amount of stem, which reduces its alkaloidal percentage.

Constituents.—The important constituents of Henbane are the alkaloids hyoscyamine and hyoscine, also known as scopolamine. Their combined percentage is ordinarily from 0.08 to 0.15 per cent. Their relative percentages are extremely difficult of determination, but the amount of hyoscyamine is many times greater than that of hyoscine.

Gerhard extracted and examined the odorous principle of Henbane, and found it a butyric compound, probably a butyric ether or a butyrin. Resin, fixed oil, and ordinary plant-constituents are also present.

Assay of Hyoscyamus.—As stated above, the alkaloids of hyoscyamus are present only in small quantity, and the U. S. Pharmacopœia demands that the leaves shall contain not less than 0.08 per cent. when assayed by the methods given for BELLADONNA (see page 286), using, however, 25 Gm. of hyoscyamus, in No. 60 powder, in place of 10 Gm. of belladonna. The increased quantity of drug is necessary on account of the small yield of alkaloid.

Pharmaceutical Preparations.—EXTRACT OF HYOSCYAMUS, FLUIDEXTRACT OF HYOSCYAMUS, TINCTURE OF HYOSCYAMUS, U. S. P.

Action and Uses.—Hyoscyamus is closely allied to belladonna in its action, but is more of a sedative to the nervous system. It may be employed in all of those conditions in which the latter drug is indicated. Combined with silver nitrate it is especially useful in the treatment of gastric ulcer and chronic gastric catarrh. It has also been highly recommended in the treatment of hysteria, whooping-cough, nervous cough, and colic. When combined with purgatives it is a useful drug to prevent their griping effect. The extract in the form of a suppository is frequently employed to relieve the pain of hemorrhoids, and a poultice made from the leaves may be applied to allay the pain of cancerous and other ulcers. For the symptoms of poisoning by hyoscyamus and the treatment of this condition, see BELLADONNA. The powdered leaves are given in doses of from 5 to 10 grains (0.30–0.60 Gm.); the alcoholic extract, from $\frac{1}{2}$ to 2 grains (0.03–0.12 Gm.); and the tincture, from 1 to 2 fluidrachms (4–8 Cc.).

Allied Drugs and Other Species.—Henbane seeds are also very largely used. They are roundish, reniform, and flattened; have a gray-brown, finely and densely rough-pitted testa, and contain a whitish oily albumen which encloses a curved embryo of the shape of the figure 9. The hilum is in the concave side of the seed. The seeds are without odor, and have an oily, bitter, and acrid taste. Their composition, as to active constituents, is identical, except that the percentage of alkaloids is a trifle lower than that of the herb. They contain in addition about 25 per cent. of fixed oil. The bitter glucoside *hyoscypicrin* ($C_{27}H_{52}O_{14}$) is neutral, soluble in alcohol and water, precipitated by tannin, and is decomposed into sugar and a yellowish-white resin.

The genus *Hyoscyamus*, L., comprises 11 species. All those which have been investigated contain similar principles and possess similar properties to those of the one above described.

H. muticus L. is considerably used as a narcotic, in India, under the name *Sakran*. Dunstan reported it as containing about 1 per cent. of hyoscyamine, which was readily extractible.

Duboisia, the leaf of *Duboisia myoporoides* R. Br. (*Corkwood elm*), a tree or large shrub of Australia, is the practical equivalent of Belladonna or Henbane. It is 3 or 4 inches long, by about a sixth as broad, lanceolate, with tapering ends and entire, smooth, thickish, and drying of a brownish color. As they reach the market the leaves are usually much broken. They possess a slight narcotic odor and a bitter taste. With ordinary plant-constituents, Duboisia contains about 1 per cent. of alkaloid, mostly hyoscyamine, with a little hyoscine and the crystalline alkaloid *pseudohyoscyamine* ($C_{17}H_{23}NO_3$), which is peculiar to this plant, so far as known (see description above, under Hyoscyamine). *D. Leichardtii* F. v. Müll., said to contain a larger amount of alkaloid, the nature of which has not been definitely ascertained, is probably only a form of the last. Duboisia is rarely employed in medicine, but the

sulphate of its alkaloid duboisine may be used as a mydriatic in the various conditions in which atropine is indicated. Taken internally it is said to possess soporific properties, and may be given interchangeably with hyoscine in the treatment of insanity. If given in full dose, it sometimes occasions vomiting without nausea, and leaves a peculiar soapy taste in the mouth. Excessive doses are said to produce muscular weakness and coma without delirium or convulsions. Extreme dryness of the fauces occurs, but, as a rule, flushing of the face is absent. Occasionally, it may produce salivation or severe sweating when idiosyncrasy exists. The treatment of the symptoms of poisoning consists in stimulation with brandy as needed, the application of external heat, and rest in bed. The remedy has been given quite largely in the treatment of paralysis agitans, and is said to be of value in the treatment of psychic epilepsy. The dose of duboisine sulphate hypodermically is from $\frac{1}{80}$ to $\frac{1}{60}$ grain (0.0008–0.001 Gm.). As a mydriatic it may be instilled into the eye in aqueous solution 1 grain to the ounce (0.05 Gm.–30 Cc.).

D. Hopwoodii F. v. Müll., also Australian, yields the *Pituri* ("*Pitchery*" or "*Pedgery*") *leaves*, so largely used by the Australian natives for chewing and smoking, as tobacco is used. Like tobacco, it varies greatly in its percentage of alkaloid (piturine), which has been extracted to the extent of 2.5 per cent. *Piturine* ($C_{12}H_{16}N_2$) is a heavy liquid alkaloid, of a sharp, biting taste, and pungent odor, miscible with water, alcohol, and ether, closely resembling nicotine.

I.

ICHTHYOCOLLA.—Isinglass.

Colla piscium.—Fish glue, E.; *Hausenblase, Fischleim*, G.; *Ichthyocolle, Colle de Poisson*, Fr. Cod.; *Cola de pescado*, Sp.; *Gelatina* (or *Gomma*) *de Peixe*, Port.; *Colla* (or *Gelatina*) *de Pesca, Itiocolla*, It.

The dried swimming-bladder of *Acipenser Huso* L. and of other species of *Acipenser* (Class *Pisces;* Ord. *Sturiones*).

Ichthyocolla is official in nearly all pharmacopœias, but they differ greatly in their statements of its solubility in boiling water to form a jelly on cooling, the amount of water named varying from 24 to 50 parts. The amount of ash is given as 0.5 per cent. by the Russian, 1 per cent. by several others. The Italian points out that ichthyocolla is precipitated by tannic acid, but not by iron salts.

Origin.—The sturgeons named in the definition chiefly inhabit the waters of, and tributary to the Black and Caspian seas, and this product is known as Russian isinglass. It is prepared by cutting the air-bag or swimming-bladder open, washing and soaking it in water, and spreading it upon boards, the outer silvery membrane being turned upward and removed by rubbing. The bladder is then merely dried in sheets, and constitutes *leaf isinglass*, or several are put together and then folded before they are completely dry, forming *book isinglass*, or each bladder is rolled up, and folded around a few pegs in the form of a horseshoe, heart, or lyre, in which shape it is dried. The latter is the *staple isinglass*, which, according to its dimensions, is again divided into *long* and *short* staple. The kind now most commonly met with in United States commerce is the leaf isinglass.

Description.—Russian isinglass is a somewhat horny and tough membranous tissue, which is semitransparent, of a whitish or pale-yellowish color, pearly appearance, and iridescent; it is easiest torn in the direction of its fibers, is inodorous, and quite insipid in taste. Immersed in water or diluted alcohol, it swells, becomes opaque, and dissolves at a somewhat elevated temperature, leaving a flocculent residue not exceeding 2 per cent.; on cooling, its solution with 24 parts of water congeals to a transparent jelly. On incineration, it leaves 0.5 per cent. of ash. Isinglass which is discolored, of bad odor, or less soluble in water, is not adapted for medicinal purposes.

Constituents.—Besides membranous matter and some salts, isinglass consists of that variety of gelatin known to chemists as *glutin*. (See GELATINUM, p. 709.)

Adulterations.—In the place of Russian isinglass the swimming-bladder of other fishes is sometimes sold, and the intestines of various animals are said to be coated with gelatin and used for a like purpose. Such substitutions or adulterations are easily recognized by the larger amount of ash (3 to. 10 per cent.) left on incineration or by the larger proportion of matter insoluble in hot water. Gelatin immersed in cold water swells, retains its transparency, and becomes soft and easily disintegrated.

Action and Uses.—Isinglass was at one time employed as a protective to the skin for the same conditions for which we now use collodion. It has also been used in place of gelatin to aid the digestibility of milk by preventing the formation of tough curds.

Other Varieties of Isinglass.—The air-bags of most large fishes appear to be adapted for some of the purposes for which isinglass is used in the arts; when they are dried without being split open they are known as *purse* or *pipe isinglass*.

American isinglass, according to C. T. Carney (1857), is prepared from the sounds of *Gadus merluccius* L., or *hake;* they are cleansed, soaked in water, passed through rollers, and dried in the form of ribbons (*ribbon isinglass*) or thin and transparent sheets (*sheet isinglass*). C. C. Meyer (1873) found the former to leave 30 per cent., and the latter only 18 per cent., of matter insoluble in water; a fresh hake-bladder weighing 15 ounces left 1 ounce undissolved. Storer states that the swimming-bladder of *Otolithus regalis* Cuvier, the *weakfish*, likewise furnishes some isinglass.

Brazilian isinglass comes from species of the genera *Pimelodus* and *Silurus*, the entire sounds being often dried so as to adhere together (*lump isinglass*), and the lumps are sometimes split open (*honeycomb isinglass*). A false isinglass from Para consisted, according to Pereira (1853), of the ovaries of a fish, probably *Sudas gigas*.

East Indian isinglass is produced from several large fishes, and is met with in the form of purses and of leaves.

Japanese or *Chinese isinglass* is a vegetable product. (See AGAR-AGAR.)

ICHTHYOLUM.—Ichthyol.

The name ichthyol, derived from the Greek ἰχθύς (*ichthus*, fish), is commercially applied to the ammonium salt of ichthyolsulphonic acid. Other compounds are designated by prefixing the name of the respective base, as sodium-ichthyol, calcium-ichthyol, etc.

The source of all ichthyol compounds is a crude oil—ichthyol-oil—resulting from the destructive distillation of a bituminous rock filled with fossil fish and found in large quantities near Seefeld, in the Tyrol mountains of Europe, at an elevation of 3000 to 4000 feet. This oil is a brownish-yellow transparent liquid of 0.865 specific gravity, boiling between 100° and 225° C. (212° and 437° F.), and possessing a peculiar penetrating, somewhat aromatic odor. If subjected to fractional distillation, about 6 per cent. will pass over between 100° and 120° C., 53 per cent. between 120° and 160° C., 33 per cent. between 160° and 225° C., and about 6 per cent. between 225° and 255° C. It contains about 10 per cent. of sulphur, which is combined in a manner not yet explained, and cannot be extracted by boiling with alkali hydroxide solution nor by treatment with sodium amalgam.

When crude ichthyol oil is mixed with an excess of concentrated sulphuric acid the mixture becomes heated spontaneously to near 100° C. (212° F.), evolves much sulphur dioxide, and forms ichthyoldisulphonic acid ($C_{28}H_{36}S.(SO_3H)_2$?), which latter may be separated in form of a dark extract-like mass, by repeated treatment with concentrated solution of common salt, whereby sulphurous and sulphuric acids are removed. The dark mass consists of 3 distinct substances: ichthyoldisulphonic acid proper, which may be extracted by absolute alcohol; a sulphone, to which the odor is due, and which may be extracted with petroleum ether; and a third substance soluble in alcohol and benzene. The acid, which is dibasic, forms salts with organic and inorganic bases and is used for the preparation of the various ichthyol compounds.

Ichthyol or Ammonium-ichthyol. *Ammonium Ichthyolsulphonate.*—This, as stated above, is the article commercially known simply as ichthyol, and is prepared by neutralizing ichthyolsulphonic acid with concentrated ammonia water and evaporating the product to the consistence of a syrupy extract. It is a clear, reddish-brown syrupy liquid with a bituminous odor and taste, soluble in water, glycerin, and in a mixture of equal volumes of ether and alcohol. Alcohol or ether alone takes up only a part of it, so also petroleum ether. Dried on a water-bath ammonium ichthyolsulphonate loses about 45 per cent. of its weight, the residue when heated and ignited intumesces and burns without residue upon continued heating. It is employed usually in the form of an ointment (10 to 50 per cent.), made with lanolin or petrolatum. From a 10 per cent. aqueous solution acids precipitate the dark resinous ichthyolsulphonic acid. Fixed alkali hydroxides added to the solution liberate ammonia. The ammonium salt should be dispensed when "ichthyol" is called for without further specification.

Ichthyol may be rendered quite odorless by treatment with hydrogen peroxide. 200 parts of ammonium-ichthyol are mixed with 250 parts of distilled water and 100 parts of hydrogen peroxide ("10 volumes") solution and allowed to stand in the cold until the peculiar odor of ichthyol has disappeared, after which the solution, previously neutralized with ammonia, is evaporated to 200 parts. Deodorized ichthyol is commercially marketed under the name of "Desichtol."

When ichthyol is dried and extracted with absolute alcohol the residual purified mass constitutes the commercial "Anytin." The latter in a dry form is a brown hygroscopic mass soluble in water in all proportions. Anytin occurs usually in a thick, syrupy form, leaving about 50 per cent. of residue upon drying. It is used as a solvent for substances otherwise difficultly soluble in water, the combinations being termed anytoles.

Sodium-ichthyol. *Sodium-ichthyolsulphonate.*—This may be prepared by neutralizing ichthyolsulphonic acid with an aqueous solution of sodium hydroxide. It contains from 20 to 30 per cent. of water, and is a dark-brown mass resembling the ammonium compound in general solubilities. It leaves a strongly alkaline ash on ignition which evolves the odor of hydrogen sulphide upon the addition of an acid.

It is distinguished from "ichthyol" in not giving off ammonia upon the addition of sodium hydroxide solution. It contains about 15 per cent. of sulphur. Other salts of ichthyolsulphonic acid may be prepared by direct neutralization of the acid with the oxide or carbonate of the respective metal, or by an organic base. When the compound is insoluble, it may be prepared by transposition by precipitation of a solution of the salt with ammonium ichthyolsulphonate. The various compounds may be rendered quite odorless and tasteless by heating to 125° and 140° C. (257° and 284° F.), or by extraction with alcohol.

The salts of metallic bases which have been introduced commercially are the Lithium-ichthyol, Zinc-ichthyol, Calcium-ichthyol, containing 2.5 per cent. of calcium; Ferricthol, containing 3.5 per cent. of iron; Ichthargol, containing 12 per cent. of silver; and Ichthermol, containing 24 per cent. of mercury.

The two first-named compounds resemble sodium-ichthyol in appearance, while the four latter occur as brown odorless and tasteless powders, insoluble in water.

Action and Uses.—Ichthyol has been extensively employed both internally and externally as an alterative and antiseptic. Its efficiency is thought by those who have used it most, to depend upon the sulphur which it contains. When given internally, it is said to decrease tissue-waste, and for this reason it has been employed in the treatment of tuberculosis and other chronic wasting diseases. Ichthyol has been employed both internally and externally in the treatment of gouty, rheumatic, and scrofulous conditions. An ointment containing 50 per cent. of this drug in lanolin is one of the best remedies we have for the local treatment of erysipelas and acute articular rheumatism; and the same may be employed as a remedy for many chronic skin affections, such as acne, acne rosacea, and eczema, in their indurated forms, and lupus. This drug is said to be particularly efficacious also as a local application to burns, scalds, frostbites, and chilblains. Tampons containing ichthyol are frequently introduced into the vagina for the purpose of promoting the absorption of pelvic exudates, and rectal suppositories containing from 2 to 10 grains (0.12–0.60 Gm.) are said to allay the pain of anal fissure and afford relief in chronic prostatitis. A 1 per cent. aqueous solution has been highly recommended as an injection in the treatment of gonorrhœa. The internal dose of ichthyol is from 2 to 10 grains (0.12–0.60 Gm.), given either in pill or capsule.

Other Derivatives of Ichthyol.—Ichthalbin. *Ichthyol albuminate. Ichthyol-Eiweiss*, G.—Ichthalbin is prepared by precipitating a solution of albumin by a solution of ichthyolsulphonic acid, washing the precipitate with water, drying it at 25°–30° C. (77°–86° F.) and later at 100° C. (212° F.). A grayish-brown powder, insoluble in water and in the juices of the stomach, but is decomposed in the intestinal canal into albumin and ichthyolsulphonic acid. It is prescribed in doses of 1–2 Gm., 3 times per day, to be taken before meals.

Ichthoform.—A combination of ichthyolsulphonic acid with formaldehyde. It is a dark-brown, odorless, tasteless powder, insoluble in water and dilute acids, soluble slowly in alkaline solutions, and only partly soluble in alcohol or ether. It contains about 14.5 per cent. of sulphur. It is prescribed in doses of 8 Gm. per day for internal use, and applied externally as a substitute for iodoform.

Allied Substances.—Thiolum.—*Thiol.*—This compound has been proposed as a substitute for ichthyol, and occurs both in dry and liquid form. It is prepared by heating brown-colored paraffin or gas oils of 0.890 to 0.900 specific gravity with sulphur and extracting the sulphurated unsaturated hydrocarbons with alcohol. Upon removing the alcohol by distillation a dark-brown oily liquid remains; this oil when treated with concentrated sulphuric acid is changed into a water-soluble compound, which is then purified by ammonia to remove free acid, and finally precipitated by sodium chloride or sulphate. Pure thiol is a neutral solid body, non-hygroscopic and soluble in water; it occurs in powder form and also in aqueous solution, the former of dark-brown color, and the latter a dark reddish-brown syrupy liquid, containing about 40 per cent. of thiol.

Tumenolum—*Tumenol.*—This is a mixture of sulphones and sulphonic acids, obtained from purified mineral oils by the direct action of concentrated sulphuric acid, without previous sulphuration. It occurs as a dark-colored acid syrup; the separated sulphones (extracted by ether from a neutral mixture prepared with soda) are known as tumenol oil, a dark-yellow thick liquid, insoluble in water, but readily soluble in ether and benzene. Crude tumenol may be freed from adhering acid by repeated solution in water and precipitation by sodium chloride; it is a tough brown mass, resembling ichthyol, and consists of a mixture of tumenol, sulphone, and tumenolsulphonic acid; the latter substance occurs as a dark-colored faintly bitter powder, readily soluble in water. Like ichthyol and thiol, tumenol has been successfully employed in eczema, pruritus, etc.

ILEX.—Holly.

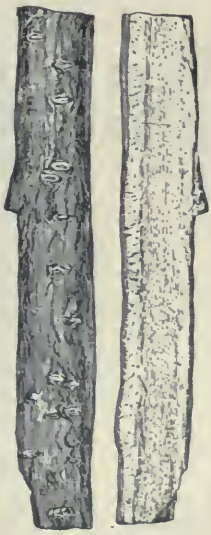
The genus *Ilex*, L. (Fam. *Ilicineæ*), comprising about 150 species, mostly of tropical America, but some extending into temperate regions, is of much interest because of the fact that several of its species contain caffeine and are used like tea. These will be found discussed under THEA. The following species possess more or less medical interest:

The title *Ilex* or *Holly* is commonly understood to apply to the leaves of several species, especially to those of *I. aquifolium* L., the *European Christmas, Crocodile, Sparked* or *Prick holly*, or *Hollen, Stechpalma* or *Christdorn* (G.), *Houx* (Fr.), or *Acebo* (Sp.). This species is a shrub or small tree, rather widely distributed through Europe, and also cultivated, and contributes the well-known red-berried and spiny-leaved evergreen branches so largely used for Christmas decoration, and the fine hard, white holly-wood of the cabinet-makers. The scarlet fruits are commonly known as *Poison-berry* and are bitter and reputed emetico-cathartic poisonous, though these properties have not been investigated. The inner bark is said to be used in the manufacture of bird-lime. Although this species is somewhat imported into the United States, that chiefly used here for decorative purposes, as well as for its wood, is the closely related and very similar species *I. opaca* Ait. (*I. quercifolia* Meerb.), abundant in the eastern and central United States, especially southward. Both leaves are shortly and stoutly petioled, 4 to 5 Cm. (about 1½ to 2 In.) long, evergreen, thick, tough and leathery, and with a wavy-toothed margin, the teeth terminating in spines. The European are mostly ovate, the American mostly oval or rounded and more glossy. Various active constituents of the leaves have been reported by different analysts, but their reports are very discordant. An acrid, alliaceous volatile oil exists in small amounts. The bitter principle is extracted by both alcohol and water. That extracted from the European variety has been called *ilicin*, but since it is unknown in a pure form, it is uncertain whether the bitter principle of the American leaves is identical. From the European leaves was also obtained water-soluble, syrupy *ilicic acid*, yielding scaly crystals with calcium, but amorphous with barium, and the yellow coloring-matter *ilexanthin* ($C_{17}H_{22}O_{11}$). The latter is yellow, melts at 198° C. (388.4° F.), is scarcely soluble in water or ether, but soluble in alcohol, yields an orange precipitate with lead acetate, and does not reduce Fehling's Solution. The leaves of European holly are reported to be diaphoretic and antiperiodic. They were formerly employed in decoction in the treatment of catarrhal and rheumatic conditions and in intermittent fever, but at present they are rarely used. American holly (*I. Opaca*) is said to be demulcent and expectorant, and to possess also the same properties as the European variety.

FIG. 224.

Prinos (⅔ Nat.).

FIG. 225.



Prinos (Nat.).

Prinos, Black, False or *Striped alder, Winter-berry*, or *Feverbush*, is the bark of *I. verticillata* (L.) A. Gray (*Prinos v.* L.), a dicœciously polygamous shrub or small tree, with deciduous leaves, growing in swampy or low ground throughout eastern North America. Its abundant, beautiful, scarlet, shining fruits persist into the winter season. The bark occurs in slender,

partially quilled strips or fragments, about 1 Mm. ($\frac{1}{25}$ In.) thick, externally of a brownish-ash color with ashy-gray or whitish patches which have blackish margins and are sprinkled with minute black or dark-brown circular spots. The older pieces have short, oblong, transverse markings. The inner surface varies from pale-green or greenish-white to deep-yellow, is short-striate, and often bears strips of adhering white wood. It is fragile, the fracture short, and showing a greenish color and a tangential structure. The odor is slight and peculiar, the taste bitter and astringent. This drug has not been subjected to careful chemical analysis, though Collier has reported the bitter principle as being amorphous and yellow and existing in connection with considerable tannin and resin and small amounts of starch, sugar, and wax.

Black alder has been employed for its tonic and astringent properties. It is used in the treatment of diarrhœa, and was formerly substituted for cinchona in the treatment of periodical fevers, but it is probably of no more value than other simple bitters for combating the latter condition. It has also been employed both internally and locally in the treatment of ill-conditioned ulcers and chronic skin eruptions. It may be given in doses of 30 grains (1.94 Gm.); or a decoction made by boiling 2 ounces (62 Gm.) of the drug with 3 pints (1420 Cc.) of water until only 1 quart (946 Cc.) remains, may be given in doses of from 1 to 3 fluidounces (30–89 Cc.), as required.

The similar bark of *I. lævigata* (Pursh.) A. Gray (*Prinos l.* Pursh.), the *Smooth winter-berry* or *Hoopwood*, of the eastern United States, and that of *I. glabra* (L.) A. Gray (*Prinos g.* L.), the *Ink-berry*, *Gall-berry* or *Evergreen winter-berry*, of the southeastern United States, extending northward to Massachusetts, are said to be similarly employed.

ILLICIUM.—Illicium.

Anisi stellati fructus, Br.; *Semen badiani.*—*Star-anise*, *Chinese anise*, E.; *Sternanis*, G.; *Badiane*, *Anise ẽtoilé*, Fr.; *Semen estrellado*, Sp.; *Aniz Estrellado*, *A. da China*, Port.; *Anice Stellato*, It.

The dried fruit of *Illicium verum* Hook. f. (Fam. *Magnoliaceæ*).

Illicium is official in most pharmacopœias, among which there is great confusion between the botanical name of this and those of the Japanese or poisonous variety; yet nearly all caution against the substitution of the latter. The drug was known to science long before the plant which yielded it, and when Linnæus received specimens of the Japanese tree with the statement that it was the source of the Chinese drug, he described and figured it as *I. anisatum*. The real Chinese anise tree thus remained without a botanical name and description until published by the younger Hooker as *I. verum*. Thus, through the error of Linnæus, "I. anisatum" becomes a mere synonym with *I. religiosum* Sieb., and does not belong to the drug at all.

Fig. 226.

Illicium verum.

Fig. 227.

Illicium religiosum.

Origin.—From a beautiful large evergreen shrub or small tree of the mountains of southern China.

Description.—From 2 to 4 Cm. ($\frac{4}{5}$ to $1\frac{1}{2}$ In.) broad, consisting of 6 to 10 (usually 8) radially arranged follicles, each 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) long and about two-thirds as broad, laterally flattened, broadly ovate, abruptly contracted into a short, nearly straight beak, dark-brown, more or less rough-wrinkled, especially on the lower edge, but not knotty nor woody, dehiscent along the upper (inner) edge to show the light yellow-brown, somewhat shining, inner surface, and the solitary, strongly shining, brown seed; odor pleasantly aromatic, resembling anise, as does the taste.

Very dark, knotty and woody Illicium, with the beaks strongly and abruptly upturned, the taste bitter, is the poisonous *I. anisatum* L., and should be rejected.

Constituents.—The pericarp constitutes about 78 per cent., the seeds about 22 per cent. of the weight of the drug. The latter are oily and little aromatic, the active portion residing more abundantly in the former. Ostwald found the pericarp to contain about 5 or 6 per cent. of volatile oil, and about 1.5 per cent. of fixed oil, while the seeds contained 2.5 to 3 per cent. of volatile and between 20 and 25 per cent. of fixed oil. He also found a little protocatechuic and a little shikiminic acids. There are also about 10 per cent. of resin in the pericarp, 2 to 3 per cent. in the seeds, and a little mucilage and pectin. Reference to the presence of an alkaloid in this species does not appear to have been verified. (For an account of the volatile oil, see Oleum Anisi.)

Action and Uses.—Star anise, like the official anisum (which see), possesses the properties of a stimulant carminative and anodyne, and may be employed in the treatment of flatulent colic and dyspepsia. Its oil is commonly employed, but the powdered drug may be given in doses of from 10 to 20 grains (0.60–1.3 Gm.), either in substance or in infusion.

Allied Products.—*Japanese star anise*, from *I. religiosum* Sieb. et Zucc. (*I. anisatum* L.; *I. Japonicum* Sieb.), is very similar, but it is woody and shrivelled, has near the apex a short and rather deep depression, terminates with a short curved beak, and has a faint clove-like odor and an unpleasant taste. The plant is known in Japan as *Sikimi* or *Shikimi*. Eykman found in the fruit an alkaloid and a poisonous neutral principle, *sikimin*, which crystallizes in hard prisms or needles, is insoluble in hot water, ether, and chloroform, and easily soluble in alcohol and glacial acetic acid. The volatile oil is somewhat heavier than water, slightly lævogyre, reduces ammoniacal silver solution, and consists of a terpene boiling near 175° C. (347° F.), and of liquid anethol boiling at 232° C. (350° F.). Although poisonous, this fruit is used by the natives as a spice. Six other species, two of them natives of our Southern States, are known. All have aromatic barks and fruits, but none is like the official. *I. Floridanum* Ellis (*Poison bay* or *Stink-bush*), of our Gulf region, is reputed poisonous in all parts.

INDIGO.—Indigo.

Indicum, Pigmentum indicum.—Indigo, Fr., G., Sp.; *Indigoblau*, G.; *Indaco*, It.; *Añil*, Sp.

A blue dyestuff extracted from different species of *Indigofera* (Fam. *Leguminosæ*).

Origin.—The genus consists of herbaceous or suffruticose plants which are indigenous to and cultivated in tropical and subtropical countries. The most important species are *Indigofera tinctoria* L. (*I. indica* Lamarck), *I. Anil* L., and *I. argentea* L. (*I. glauca* Lamarck, *I. cærulea* Roxb.). The same coloring-matter is also contained in the *woad*, *Isatis tinctoria* L. (*Cruciferæ*), of Europe, in *Polygonum tinctorium* L. (*Polygonaceæ*), of China, in *Gymnema* (*Asclepias*) *tingens* Sprengel, and in *Wrightia* (*Nerium*) *tinctoria* R. Brown, of Hindostan, which plants are employed for dyeing.

Indigo was known in the East from the earliest times, but was not introduced into Europe until the sixteenth century, where, owing to the *woad* (*weid*, *pastel*) industry, its use was restricted and prohibited until its use was finally permitted about 1737 through legal enactment.

The principal supply of natural indigo comes from Bengal, about 2000 tons, with Madras and Central America producing about 500 tons each, and Manila, Java, Bombay, China, and other countries producing together about 1000 tons per annum. The importations into the United States in 1900 were crude indigo 2,747,043 pounds ($1,446,490), indigo carmine 18,204 pounds ($15,787), extracts or pastes of indigo 251,538 pounds ($20,094). The average annual importation of crude indigo into the United States from 1891 to 1900 was 2,745,666 pounds, the lowest 1,717,635 pounds in 1894, and the highest in 1895, amounting to 3,411,539 pounds.

Preparation.—The plants immediately after blooming are packed in bundles, covered with water in vats and subjected for 10 to 18 hours to fermentation. The coloring-principle is mostly in the leaves, and is extractable in 2 hours (A. Schulte, *Ber. D. Phar. Ges.*, 1902, 12, pp. 19–30) at 53° C. (127.4° F.). When the liquor has turned a yellowish-green color it is aërated for several hours by brisk stirring, whereby the *indican* is oxidized to the insoluble indigo-blue, which rapidly deposits after the liquid is at rest. Addition of milk of lime or ammonia hastens the settling and also produces a better product. The supernatant liquid is then drawn off and the residue boiled to check fermentation, after which the indigo-blue is washed, collected, pressed, and dried. The yield is about 0.3 per cent.

Properties.—Indigo is met with in the form of porous, hard, but brittle lumps or cubical cakes, which are inodorous, tasteless, and of a deep-blue color, assuming a coppery luster when scratched or rubbed with a hard body. Inferior qualities are of a dull hue, with a greenish or grayish tint, dense, firm, and not brittle. The commercial varieties are classified by Sadtler as "first the Asiatic, of which the Bengal is the best, followed by the Java, Madras, Coromandel, and Manila varieties; second, the American, of which the Guatamala is the best, followed by the Caracas and the Brazilian varieties; and, third, the African, including the Egyptian, Senegal, and the Isle of France varie-

ties." The best varieties are lighter than water and show a coppery hue where rubbed with a hard object, and when burned do not leave over 7 per cent. of ash, and do not contain over 6 per cent. of water. Indigo is hygroscopic. Indigo is insoluble in the ordinary solvents, dissolves freely in concentrated sulphuric acid, and when rapidly heated sublimes partly at about 300° C. (572° F.) in purple colored vapors which sublime in copper-colored needles. The blue color of indigo is destroyed by reducing agents in the presence of alkali and by oxidizing agents.

Constituents.—Indigo varies much in composition, containing from 20–80 per cent. of indigotin (indigo-blue), 5–18 per cent. of moisture, 2–10 per cent. of indigo-red, 1–6 per cent. of indigo-brown, 1–5 per cent. of indigo-gluten, and leaves upon incineration 3–20 per cent. of ash. The value of indigo lies principally in the amount of indigotin which it contains. Rawson recommends the following process for assay: 1 Gm. of the sample of indigo, finely pulverized, is mixed in a small mortar with about its own weight of ground glass. This mixture is gradually added during constant stirring with a glass rod to 20 Cc. of concentrated sulphuric acid (specific gravity 1.845), which is then heated to about 85° C. (185° F.) for 1 hour. The product is then cooled, diluted with water to about 1 liter, and filtered from indigo-brown and other insoluble matter. 50 Cc. of the filtered solution are treated with 50 Cc. of water and 32 Gm. of common salt, which quantity is almost sufficient to saturate the solution. After standing for 2 hours the solution is filtered, and the precipitate washed with about 50 Cc. of brine of 1.2 specific gravity. The precipitated *sodium sulphindigotate* is dissolved in hot water, the solution cooled, mixed with 1 Cc. of sulphuric acid, and diluted to 300 Cc. This solution is then titrated in a porcelain dish with a solution of potassium permanganate containing 0.5 Gm. of $KMnO_4$ per liter, the exact oxidizing power of which has been ascertained by experiment with a solution of pure indigotin. This is made by dissolving 0.5 Gm. of indigotin in strong sulphuric acid, diluting the solution to 1 liter, and employing 50 Cc. and 250 Cc. of water for the titration. The oxidation is regarded as complete when the liquid, which first takes a greenish tint, changes to a light-yellow, with a faint-pink color in the margin. In place of the above permanganate solution a $\frac{N}{50}$ solution containing 0.6324 Gm. of $KMnO_4$ per liter may be used for the titration. Each Cc. of this solution oxidizes 0.0015 Gm. of indigotin.

Indican, $C_{26}H_{31}NO_{17}$, the mother-substance of indigo-blue, was first isolated by E. Schunk. It is a colorless syrupy bitterish glucoside, soluble in water, alcohol, and ether, dissolves in dilute alkaline solutions to a bright-yellow solution, and when boiled with concentrated alkali evolves ammonia. The alcoholic solution gives a yellow precipitate with lead acetate. When treated with dilute acids indican is split up into *indigotin* and *indiglucin*, $2C_{26}H_{31}NO_{17}$ (indican) $+ 4H_2O = C_{16}H_{10}N_2O_2$ (indigotin) $+ 6C_6H_{10}O_6$ (indiglucin). The same change occurs during the fermentation of the plants, as described above, when the indican disappears.

Indigotin. *Indigo-blue*, $C_{16}H_{10}N_2O_2$, or $C_6H_4<\begin{matrix}CO\\NH\end{matrix}>C:C<\begin{matrix}CO\\NH\end{matrix}>C_6H_4$. Molecular weight, 260.18.

Indigotin occurs as a neutral, odorless, tasteless, dark-blue powder or as purplish to copper-hued rhombic crystals. It is insoluble in water, dilute acids or alkalies, alcohol, ether, and oils. It is but slightly soluble in hot alcohol, acetone, or amyl alcohol, more readily in chloroform, or boiling solutions of glacial acetic acid, phenol, aniline, and nitrobenzene, from which solutions it may be recovered in the crystalline form on cooling. It is sublimable in a vacuum without decomposition, but when subjected to dry distillation by itself it sublimes in part and yields aniline. Oxidizing agents destroy the color and yield *isatin*, $C_8H_5NO_2$, which subjected to dry distillation yields aniline. With strong nitric acid, isatin, nitrosalicylic acid, and picric acid result. It is soluble in cold concentrated sulphuric acid with a yellowish-green color, which on exposure to air, or more rapidly on heating, turns blue, forming indigosulphonic acid. According to conditions, varying amounts of monosulphindigotic acid (sulphopurpuric acid, indigo-purple), $C_{16}H_9N_2O_2.HSO_3$, and disulphindigotic acid (sulphocœrulic acid), $C_{16}H_8N_2O_2(HSO_3)_2$, are obtained; the first one of these is insoluble in dilute acids, in which the second remains dissolved, and is obtained pure by transferring it from its dilute solution to wool and dissolving it from the latter by means of a weak alkali. The sodium salt of this latter is sold in commerce as *indigo-carmine*, and is usually obtained by adding a sodium salt to a solution of sulphate of indigo ("soluble indigo," prepared by

gradually adding 1 part of powdered indigo to 5 parts of Nordhausen sulphuric acid or 8 parts of oil of vitriol, and preventing a rise of temperature by immersing the vessel in cold water), washing the precipitate with a solution of the same salt, and expressing; the product is soluble in cold water. By the action of reducing agents in alkaline solutions, or hyposulphite in acid solution indigotin by assimilation of hydrogen is reduced to *indigo-white* (*hydringotin, reduced indigo*), $C_{16}H_{12}N_2O_2$. Indigo-white is a grayish-white amorphous substance, insoluble in water and dilute acids, but soluble in alkaline solutions, alcohol, ether, and chloroform, and oxidizes rapidly on exposure to air to indigo-blue.

Artificial or Synthetic Indigo.—Artificial indigo is now a successful competitor of the natural product, although the improvements made in the process for the manufacture of the latter overcame for years the earlier commercial competition by indigo synthetically prepared. The early processes of Baeyer for the manufacture of artificial indigo, for which no less than ten patents were issued in this country between May, 1880, and June, 1882, have been succeeded by more economical methods during recent years. In 1899 K. Heumann obtained four patents, Nos. 617,652, 619,488, 619,883, and 620,442, covering the use of glycocoll derivatives for the manufacture of indigo dyes, and in April, 1900, two patents, Nos. 647,279 and 647,281, were granted to T. Sandmeyer for processes for making isatin and alpha-isatinanilid, which by reduction are made to yield indigo. Sandmeyer's process threatens at present to become the most formidable rival of the natural process for making indigo.

The vastness of the industry in the manufacture of artificial indigo is shown by the data given by Lachmann regarding the Heumann process (German patent No. 91,202), as used by the Badische Anilin und Soda Fabrick, employing naphthalene as the starting-point. In the process naphthalene is oxidized by concentrated sulphuric acid to *phthalic acid*, this is converted to *phthalimide* by the use of ammonia, phthalimide to *anthranilic acid* by means of sodium hypochlorite, the anthranilic acid united with chloracetic acid to form *phenylglycocollorthocarboxylic acid*. This latter by fusion with caustic soda is converted into *indoxyl* and *indoxylic acid*, and these latter through atmospheric oxidation into *indigo*. The quantities of material involved in the operation in working up 10,000 tons of naphthalene are according to Lachmann 40,000 tons of sulphur dioxide as a by-product, 600 tons of ammonia, 2250 tons of glacial acetic acid, besides the chlorine generated from 5000 tons of salt. The process through recent improvements has been simplified by the use of sodium amide. The present production of artificial indigo is estimated at about 3,000,000 pounds per annum, or about one-fourth of the world's production.

Adulteration.—Indigo when dried at 100° C. (212° F.) should lose not over 6 per cent. of moisture, and yield not over 8 per cent. of ash when incinerated. Gum or starch, if present, forms with hot water a mucilaginous liquid or paste, and if treated with strong sulphuric acid is carbonized, coloring the indigo black. Adulteration with Prussian Blue is detected with caustic potassa or soda, which does not alter indigo, but liberates from Prussian Blue ferric hydroxide, while potassium or sodium ferrocyanide remains in solution.

Action and Uses.—Indigo was formerly employed in the treatment of nervous and menstrual disorders, but is rarely used at the present time. Large doses disorder the digestion, produce nausea and purging, and impart a bluish color to the urine and sweat. The dose is from 5 to 20 grains (0.30–1.3 Gm.).

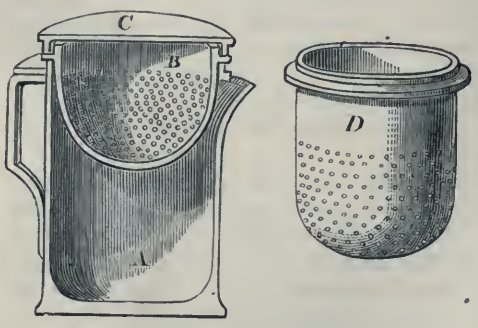
INFUSA, *U. S., P. G.*—Infusions.

Tisanes, Fr.; *Infusionen, Aufgüsse*, G.

Infusions are aqueous solutions of the soluble principles of vegetable or animal drugs obtained by maceration or digestion in hot or cold water, and differ from decoctions only in the lower degree of heat employed in their preparation. Substances containing volatile or other principles which would be dissipated or injured by boiling are particularly adapted for this purpose. Except in a few cases in which percolation is directed, the pharmacopœial infusions are prepared by pouring boiling or cold water upon the material and allowing them to remain in contact for a definite length of time, at the expiration of which the solution is poured upon a strainer, and the solid material expressed to recover the liquid absorbed by it. A convenient apparatus, well adapted for making these

preparations, is Squire's infusion-pot: this consists of a jar A, with a projecting ledge near the top, which supports a strainer, B or D, containing the material to be exhausted; the jar is closed by a well-fitting cover, C. The advantages of this contrivance are—that the material is exhausted by circulatory displacement, the liquid, as it becomes charged with the soluble ingredients descending to the bottom, giving place to fresh portions of less saturated menstruum, and that no further straining is required should care have been taken not to use too fine a powder.

Fig. 228.



Squire's infusion-pot.

The drugs are best adapted for exhaustion with water if cut into thin slices by a suitable knife, so that they may be easily permeated by the liquid; when cutting is inadmissible they should be bruised to a coarse powder. Ligneous drugs, however, should be in a fine or moderately fine powder, which is also best adapted for most of those which may be made by percolation.

The time directed for the maceration with boiling water is, in the U. S. Pharmacopœia, usually ½ hour, and in the British Pharmacopœia 15 or 30 minutes.

The strength of the infusions of the British Pharmacopœia is usually such that the virtues of 1 part of the drug are represented by 20 or 40 parts of the infusion; the simple infusions for which special directions are given in the U. S. Pharmacopœia are made in the proportion of 1½ or 4 parts to 100 parts by weight. The French Codex classifies these preparations according to their strength, and designates such, 100 or 200 parts of which represent 1 part of the drug, as *tisanes, ptisanæ;* they are made either by maceration, infusion, or decoction, and are intended to be used freely. *Apozèmes* are infusions or decoctions differing from tisanes only in being more concentrated.

Infusions are not intended to be kept, except for a very limited period. Exposed to air, as they necessarily must be in the sick chamber through the vial containing them being opened from time to time, decomposition must ensue after a day or two, and may be retarded somewhat only by keeping the vessel in a cool place, or, better still, on ice.

Nearly all the infusions will yield precipitates or become discolored with the salts of iron, lead, mercury, silver, and other heavy metals, and are therefore incompatible with them.

The U. S. Pharmacopœia has adopted the plan of ordering all infusions unless otherwise directed by the physician, and with the exception of those specially enumerated, to be made of 1 part of material to 20 parts of infusion according to the following directions: An ordinary infusion, the strength of which is not directed by the physician nor specified by the pharmacopœia, shall be prepared by the following formula: Take of the substance, coarsely comminuted, 50 Gm.; boiling water, 1000 Cc.; water, a sufficient quantity to make 1000 Cc. Put the substance into a suitable vessel provided with a cover, pour upon it the boiling water, cover the vessel tightly, and let it stand for ½ hour. Then strain, and pass sufficient water through the strainer to make the infusion measure 1000 Cc. *Caution.*—The strength of infusions of energetic or powerful substances should be specially prescribed by the physician.

The official strength of infusions is equal to about 23 grains of drug for each fluid-ounce.

The Pharmacopœia omits to direct the expression of the drug after infusion, but it is evident that bulky herbs and flowers, which are best adapted to this process, would retain a considerable proportion of the liquid, which cannot be washed out simply by passing water through the strainer to make up the deficiency in volume.

The strength of infusions of the German Pharmacopœia is double that of our own, but the general directions given for their preparation are nearly identical with the above, from which they differ only in this, that the mixture of drug and boiling water is heated for 5 minutes in a vapor-bath of boiling water, occasionally stirred, allowed to cool, and strained. The *concentrated* and *highly concentrated infusions*, made respectively with 1½ and 2 parts of drug to 10 parts of infusion, are no longer recognized.

INFUSUM AURANTII, *Br.*—Infusion of Orange-peel.

Tisane d'écorce d'orange, Fr.; *Pomeranzenschalenaufguss*, G.

Preparation.—Take of bitter orange-peel, cut small, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—A stimulant tonic and stomachic in doses of from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM AURANTII COMPOSITUM, *Br.*—Compound Infusion of Orange-peel.

Tisane d écorce d'orange composée, Fr.; *Pomeranzen- und Citronenschalen-aufguss*, G.

Preparation.—Take of bitter orange-peel, cut small, ½ ounce; fresh lemon-peel, cut small, ¼ ounce; cloves, bruised, 55 grains; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—A stimulant, stomachic, and carminative employed in doses of from 1 to 2 fluidounces (30–60 Cc.) in the treatment of flatulent colic and diarrhœa.

INFUSUM BUCHU, *Br.*—Infusion of Buchu.

Infusum diosmæ s. barosmæ.—Tisane de bucco, Fr.; *Buchuaufguss*, G.

Preparation.—Take of buchu leaves, bruised, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

A fluidounce of this infusion represents 22 grains of buchu.

Uses.—Infusion of buchu is employed for its diuretic properties and forms a convenient method for the administration of the drug from which it is prepared. The dose is from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM CALUMBÆ, *Br.*—Infusion of Calumba.

Infusion of columbo, E.; *Tisane de colombo*, Fr.; *Kolomboaufguss*, G.

Preparation.—Take of calumba root, thinly sliced, 1 ounce; cold distilled water, 20 fluidounces. Macerate in a covered vessel for 15 minutes, and strain.—Br.

The infusion made with hot water is much more mucilaginous and unsightly than if made with cold water, either by maceration or percolation. Each fluidounce represents 22 grains of calumba.

Uses.—This preparation possesses the bitter properties of columbo, and may be administered in doses of 2 fluidounces (60 Cc.), several times daily.

INFUSUM CARYOPHYLLI, *Br.*—Infusion of Cloves.

Tisane de girofle, Fr.; *Gewürznelkenaufguss*, G.

Preparation.—Take of cloves, bruised, ½ ounce; boiling distilled water, 20 fluidounces. Macerate in a covered vessel for 15 minutes, and strain.—Br.

1 fluidounce of this infusion represents 11 grains of cloves.

Uses.—Infusion of cloves is a carminative and may be employed for the purpose of overcoming nausea and vomiting and for the relief of flatulent colic. The dose is from ½ to 2 fluidounces (16–60 Cc.).

INFUSUM CASCARILLÆ, *Br.*—Infusion of Cascarilla.

Tisane de cascarille, Fr.; *Kaskarillaufguss*, G.

Preparation.—Take of cascarilla bark, in No. 20 powder, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—This forms a convenient method for the administration of cascarilla. Dose, 2 fluidounces (60 Cc.).

INFUSUM CHIRATÆ, *Br.*—Infusion of Chiretta.

Tisane de chirette, Fr.; *Chiretta-Thee*, G.

Preparation.—Take of chiretta, cut small, 1 ounce; distilled water, boiling, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—This infusion is employed as a simple bitter, and may be given in doses of from 1 to 3 fluidounces (30–90 Cc.).

INFUSUM CINCHONÆ ACIDUM, *Br.*—Acid Infusion of Cinchona.

Tisane acidulée de quinquina, Fr.; *Saurer Chinarindenaufguss*, G.

Preparation.—Red cinchona bark, in No. 40 powder, 1 ounce; aromatic sulphuric acid, 2 fluidrachms; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 1 hour, and strain.—Br.

The U. S. Pharmacopœia, 1890, directed infusion of cinchona to be made as follows, preference being given to yellow cinchona: mix 10 Cc. of aromatic sulphuric acid with 500 Cc. of water, and moisten 60 Gm. of cinchona, in No. 40 powder, with 30 Cc. of the mixture; pack it firmly in a conical percolator, and gradually pour upon it first the remainder of the mixture, and afterward water until the infusion measures 1000 Cc.

Uses.—Infusion of cinchona is employed for its tonic properties. It is too weak to be used as an antiperiodic. The dose is from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM CUSPARIÆ, *Br.*—Infusion of Cusparia.

Infusum angusturæ, U. S. 1870.—*Infusion of angustura*, E.; *Tisane d'angusture*, Fr.; *Angusturaaufguss*, G.

Preparation.—Take of cusparia bark, No. 20 powder, 1 ounce; distilled water, boiling, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

1 fluidounce of this infusion contains the virtues of nearly 22 grains of angustura bark.

Uses.—Infusion of angustura may be given for its tonic properties in the treatment of atonic dyspepsia in doses of from 1 to 2 fluidounces (30–60 Cc.), several times daily.

INFUSUM DIGITALIS, *U. S.*, *Br.*—Infusion of Digitalis.

Tisane de digitale, Fr.; *Digitalisaufguss*, G.

Preparation.—Digitalis, bruised, 15 Gm.; alcohol, 100 Cc.; cinnamon water, 150 Cc.; boiling water, 500 Cc.; water, cold, a sufficient quantity to make 1000 Cc. Upon the digitalis, contained in a suitable vessel, pour the boiling water, and allow it to macerate until the mixture is cold. Then strain, add the alcohol and cinnamon water to the strained liquid, and pass sufficient cold water through the residue on the strainer to make the product measure 1000 Cc.—U. S.

To make 1 pint of the infusion, 110 grains of digitalis should be macerated in 8 fluidounces of boiling water until cold; after straining, 13 fluidrachms of alcohol, 2½ fluidounces of cinnamon water, and sufficient cold water are to be added to bring the volume of the liquid up to 16 fluidounces.

Take of digitalis leaves, dried, 60 grains; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

The bitter taste of digitalis is masked in the first preparation by the cinnamon, and the small quantity of alcohol and oil of cinnamon will preserve the infusion for several days before a precipitate makes its appearance. Infusion of digitalis contains the water-soluble principles of the drug, chiefly digitonin and digitalin, both of which, while but sparingly soluble in water, increase the solubility of each other. It is a most valuable preparation of the drug, and its large dose, as compared with that of the tincture of digitalis, is due in part to the absence of digitoxin and other principles soluble in the hydroalcoholic menstruum of the latter preparation. 1 fluidounce of the infusion represents 7 grains U. S. P., 3 grains Br., of digitalis.

Uses.—The action of this preparation is fully described under DIGITALIS (which see). The dose is from 2 to 4 fluidrachms (8–16 Cc.).

INFUSUM ERGOTÆ, *Br.*—Infusion of Ergot.

Tisane de seigle ergoté, Fr.; *Mutterkornaufguss*, G.

Preparation.—Take of ergot, in coarse powder, ¼ ounce; boiling distilled water, 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—Br.

Uses.—The action and uses of this infusion are described under ERGOTA (which see). The dose is from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM GENTIANÆ COMPOSITUM, *Br.*—Compound Infusion of Gentian.

Tisane de gentiane composée, Fr.; *Enzianaufguss*, G.

Preparation.—Take of gentian root sliced, bitter orange-peel cut small, each, 55 grains; fresh lemon-peel, cut small, ¼ ounce; boiling distilled water, 10 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—Br.

While the U. S. P. does not recognize compound infusion of gentian, the National Formulary directs a stronger preparation to be made from which a compound infusion may be prepared by simple dilution with water. The formula is as follows:

INFUSUM GENTIANÆ COMPOSITUM FORTIUS. *Stronger Compound Infusion of Gentian.*—Take of gentian, 125 Gm.; coriander, 35 Gm.; bitter orange-peel, 35 Gm.; diluted alcohol, a sufficient quantity to make 1000 Cc. Reduce the drugs to a No. 40 powder, moisten it with diluted alcohol, pack it in a percolator, and percolate with diluted alcohol until 1000 Cc. are obtained.—N. F. When compound infusion of gentian is prescribed, mix 1 volume of this preparation with 3 volumes of water.

Uses.—Compound infusion of gentian is occasionally employed as a stimulating bitter tonic in doses of from ½ to 1 fluidounce (16–30 Cc.).

INFUSUM KRAMERIÆ, *Br.*—Infusion of Krameria.

Infusion of rhatany, E.; *Tisane de ratanhia*, Fr.; *Ratanhiawurzelaufguss*, G.

Preparation.—Take of krameria root, bruised, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

This infusion should be made in glass or porcelain vessels and all contact with metal avoided.

Uses.—Infusion of rhatany is employed for its astringent effect in doses of from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM LUPULI, *Br.*—Infusion of Hops.

Infusum humuli.—Tisane de houblon, Fr.; *Hopfenaufguss*, G.

Preparation.—Take of hops, freshly broken, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—Infusion of hops may be employed for the sedative effect of the drug in doses of from 1 to 2 fluidounces (30–60 Cc.).

INFUSUM PRUNI VIRGINIANÆ, *U. S.*—Infusion of Wild Cherry.

Tisane d'écorce de cerisier sauvage, Fr.; *Wildkirschrinden-Thee*, G.

Preparation.—Wild cherry, in No. 20 powder, 40 Gm.; glycerin, 50 Cc.; water, a sufficient quantity to make 1000 Cc. Moisten the powder with 60 Cc. of water and macerate for 1 hour; then pack it firmly in a conical glass percolator, and, having placed the glycerin in the receiving bottle, gradually pour water upon it until the infusion measures 1000 Cc.—U. S.

To make 1 pint of the infusion, 293 grains of wild-cherry bark should be macerated with a fluidounce of water for 1 hour, and then percolated with water until, after addition of 7 fluidrachms of glycerin, 16 fluidounces have been obtained.

Made with cold water as directed by the Pharmacopœia, this infusion contains volatile oil and hydrocyanic acid, which are not generated by the use of hot water.

Uses.—Infusion of wild-cherry bark may be employed for its sedative effect in the treatment of nervous cough and the cough of tuberculosis. The dose is from 2 to 3 fluidounces (30–90 Cc.), several times daily.

INFUSUM QUASSIÆ, *Br.*—Infusion of Quassia.

Tisane de quassie, Fr.; *Quassiaaufguss*, G.

Preparation.—Take of quassia wood, finely rasped, 88 grains; cold distilled water, 20 fluidounces. Macerate in a covered vessel for 15 minutes, and strain.—Br.

We can perceive no objection to the use of warm water in making this infusion, whereby time might be materially economized without interfering with the appearance

or efficiency of the preparation; maceration, as directed above, will yield a very bitter infusion, containing, however, only a portion of the quassia. If made by the general formula (see page 802), the infusion will be about five times the strength of the above.

Uses.—Infusion of quassia is employed as a simple bitter in doses of 1 or 2 fluidounces (30–60 Cc.), several times daily. Injected into the rectum it is also an effective remedy for the removal of pinworms.

INFUSUM RHEI, *Br.*—Infusion of Rhubarb.

Tisane de rhubarbe, Fr.; *Rhabarberaufguss*, G.

Preparation.—Take of rhubarb root, in thin slices, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Rhubarb being easily permeated by water, it is preferable to employ it for this purpose cut into thin slices, instead of bruising it; in the latter case the finer powder should be sifted off. But in either case the preparation is unsightly, and becomes still more so by long-continued digestion. A handsomer though weaker infusion is obtained by the formula of the French Codex, by maceration for 4 hours with cold water. In Germany a preparation has long been in use under the name of *Infusum rhei kalinum* or *Tinctura rhei aquosa*, which is now prepared as follows: rhubarb, sliced, 100 parts; borax and potassium carbonate, each 10 parts; boiling distilled water, 900 parts. Infuse for 15 minutes, add alcohol, 90 parts, and macerate for 1 hour; then express lightly, and to 850 parts of the liquid add cinnamon water 150 parts. The finished preparation represents nearly 10 per cent. of rhubarb, is of a dark red-brown color, transparent in thin layers, mixes clear with aqueous liquids, and has not an alkaline reaction, but is incompatible with all preparations which are decomposed by alkalies. It may be preserved for several months if kept in small vials and in a cool place.

Uses.—This infusion is rarely employed, but may be given when a gentle laxative is indicated, or as a vehicle for saline purges. The dose is from 1 to 3 fluidounces (30–90 Cc.), to be repeated as needed.

INFUSUM ROSÆ ACIDUM, *Br.*—Acid Infusion of Roses.

Infusum rosæ compositum.—Compound infusion of rose, E.; *Tisane de rose composée*, Fr.; *Saurer Rosenaufguss*, G.

Preparation.—Take of dried red rose petals, broken up, ½ ounce; diluted sulphuric acid, 2 fluidrachms; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

This infusion should not be made in a metallic vessel; it has a fine-red color and agreeable flavor.

A similar preparation was official in the U. S. Pharmacopœia of 1870, and may now be found in the National Formulary. It is made as follows:

Infusum Rosæ Compositum. *Compound Infusion of Rose.*—Take of red rose, 13 Gm.; diluted sulphuric acid, 9 Cc.; sugar, 40 Gm.; boiling water, 1000 Cc. Pour the boiling water upon the rose in a glass or porcelain vessel, add the acid, cover the vessel, and macerate for 1 hour. Then dissolve the sugar in the liquid and strain.—N. F.

Uses.—This acid infusion of rose has been employed for its astringent effect in the treatment of stomatitis and pharyngitis. Its virtue is principally due to the aromatic sulphuric acid which it contains, and the latter ingredient renders it a useful preparation in the treatment of night-sweats resulting from depression. It is commonly given in doses of from 2 to 4 fluidounces (60–120 Cc.).

INFUSUM SCOPARII, *Br.*—Infusion of Broom.

Tisane de genêt à balais, Fr.; *Besenginsteraufguss*, G.

Preparation.—Take of broom tops, dried and bruised, 2 ounces; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes and strain.

This preparation was introduced into the British Pharmacopœia of 1898 in place of the Decoction of Broom of the preceding issue.

Uses.—The employment of this preparation is noted under Scoparius (which see). It may be given in doses of 1 ounce (30 Gm.), every 3 hours.

INFUSUM SENEGÆ, *Br.*—Infusion of Senega.

Tisane de polygale de Virginie, Fr.; *Senegaaufguss*, G.

Preparation.—Take of senega root, in No. 10 powder, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 30 minutes, and strain.—Br.

Uses.—Infusion of senega is occasionally prescribed in doses of from 1 to 2 fluidounces (30–60 Cc.) as an expectorant.

INFUSUM SENNÆ COMPOSITUM, *U. S., P. G.*—Compound Infusion of Senna.

Infusum sennæ, Br.—*Infusion of senna, Black draught*, E.; *Tisane de séné composée*, Fr.; *Sennaaufguss*, G.

Preparation.—Senna, 60 Gm.; manna, 120 Gm.; magnesium sulphate, 120 Gm.; fennel, bruised, 20 Gm.; boiling water, 800 Cc.; cold water, a sufficient quantity to make 1000 Cc. Upon the senna and fennel, contained in a suitable vessel, pour the boiling water, and macerate it for half an hour. Then strain with expression, dissolve in the infusion the magnesium sulphate and manna, and strain again. Lastly, add sufficient cold water through the strainer to make the infusion measure 1000 Cc.—U. S.

To make 1 pint of the infusion, 440 grains of senna and 148 grains of fennel should be macerated with 13 fluidounces of boiling water for half an hour; after expression and straining 880 grains each of manna and magnesium sulphate should be dissolved in the infusion and sufficient water added to make the liquid measure 16 fluidounces.

Take of senna, 2 ounces; ginger, sliced, 55 grains; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

The first formula yields a preparation which is equivalent to the *black draught* of British pharmacy (see MISTURA SENNÆ COMPOSITA), and is recognized as such by the U. S. Pharmacopœia. The second formula may be regarded as yielding a simple senna infusion containing merely a corrective. Long-continued contact with hot water appears to increase the tendency of the senna to produce griping, particularly if digestion be resorted to. If the leaves have been cut or bruised, digestion for not over 10 minutes will yield an active infusion. The flavor being a matter of taste, the selection of aromatics had probably best be left to the physician.

POTION PURGATIVE MÉDECINE NOIRE, Fr. Cod.—Senna, 10 Gm.; rhubarb, 5 Gm.; boiling water, 120 Gm.; infuse for 30 minutes, express, and dissolve sodium sulphate 15 Gm. and manna 60 Gm.

TISANE ROYALE, Fr. Cod.—Senna, sodium sulphate, and fresh parsley leaves, each, 16 Gm.; anise and coriander, each, 5 Gm.; 1 lemon, sliced; cold water, 1000 Gm.; macerate for 24 hours.

INFUSUM SENNÆ COMPOSITUM, P. G., also known as *Aqua* (*s. Potio*) *laxativa Viennensis*—*Vienna draught*, E.; *Eau laxative de Vienne*, Fr.; *Wiener Trank*, G.—Is made by macerating 5 parts of cut senna with 45 parts of boiling water, and exposing it to the heat of a steam-bath for 5 minutes; when cold the liquid is expressed, and 5 parts of sodium and potassium tartrate, 1 part of sodium carbonate, and 10 parts of manna are dissolved in it; after straining add sufficient water up to 47.5 parts and add 2.5 parts of alcohol.

Uses.—The uses of this preparation are discussed under SENNA and MAGNESII SULPHAS. The carminative action of the fennel in the formula is said to prevent the griping effect of the senna. The dose is from 2 to 4 fluidounces (60–120 Cc.), to be repeated every hour until thorough purgation is effected.

INFUSUM SERPENTARIÆ, *Br.*—Infusion of Serpentary.

Tisane de serpentaire, Fr.; *Schlangenwurzelaufguss*, G.

Preparation.—Take of serpentary rhizome, in No. 10 powder, 1 ounce; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—This preparation has been recommended in the treatment of chronic dyspepsia. The dose is from 1 to 2 fluidounces (30–60 Cc.), as indicated.

INFUSUM UVÆ URSI, *Br.*—Infusion of Bearberry.

Tisane d' uva ursi, Fr. ; *Bärentraubenblätteraufguss*, G.

Preparation.—Take of bearberry leaves, bruised, 1 ounce ; boiling distilled water, 20 fluidounces. Infuse in a covered vessel for 15 minutes, and strain.—Br.

Uses.—Infusion of uva ursi has been employed as a diuretic in doses of from 1 to 2 fluidounces (30–60 Cc.).

INJECTIO APOMORPHINÆ HYPODERMICA, *Br.*

Hypodermic injection of apomorphine, E.; *Injection hypodermique d'apomorphine*, Fr.; *Subcutane Apomorphineinspritzung*, G.

Preparation.—Take of apomorphine hydrochloride, 1 grain ; diluted hydrochloric acid, 1 minim ; distilled water, 110 minims or a sufficient quantity. Boil the distilled water for a few minutes; cool ; add the diluted hydrochloric acid ; dissolve the apomorphine hydrochloride in the resulting liquid ; add, if necessary, sufficient recently boiled and cooled distilled water to produce 110 minims of the injection.—Br.

The solution should be recently prepared, as it does not keep well. 11 minims represent $\frac{1}{10}$ grain of apomorphine hydrochloride.

Uses.—The injection should be freshly prepared and given subcutaneously in doses of from 2 to 8 minims (0.10–0.50 Cc.).

INJECTIO COCAINÆ HYPODERMICA, *Br.*

Hypodermic injection of cocaine, E. ; *Injection hypodermique du cocaine*, Fr. ; *Subcutane Cocaineinspritzung*, G.

Preparation.—Take of cocaine hydrochloride, 33 grains ; salicylic acid, $\frac{1}{2}$ grain ; distilled water, 6 fluidrachms or a sufficient quantity. Boil the distilled water ; add the salicylic acid ; dissolve the cocaine hydrochloride in the solution when cool ; add, if necessary, sufficient recently boiled and cooled distilled water to produce 6 fluidrachms of the injection.

11 minims of this solution contain $\frac{1}{10}$ grain of cocaine hydrochloride. The addition of salicylic acid prevents the formation of micro-organisms.

Uses.—Prepare this solution as needed and give subcutaneously in doses of from 2 to 5 minims (0.10–0.30 Cc.).

INJECTIO ERGOTÆ HYPODERMICA, *Br.*

Hypodermic injection of ergot, E. ; *Injection hypodermique d'ergot de seigle*, Fr. ; *Subcutane Mutterkorneinspritzung*, G.

Preparation.—Extract of ergot, 100 grains ; phenol, 3 grains ; distilled water, 220 minims or a sufficient quantity. Mix the phenol with the distilled water ; boil for a few minutes ; cool ; add the extract of ergot, and, if necessary, sufficient recently boiled and cooled distilled water to produce 330 minims of the injection.

This solution should be prepared recently. 10 minims contain 3 grains of extract of ergot.

Uses.—This solution should be freshly made when needed, and given subcutaneously in doses of from 5 to 10 minims (0.30–0.60 Cc.).

INJECTIO MORPHINÆ HYPODERMICA, *Br.*

Hypodermic injection of morphine, E. ; *Injection hypodermique de morphine*, Fr. ; *Subcutane Morphineinspritzung*, G.

Preparation.—Morphine tartrate, 50 grains; distilled water, a sufficient quantity. Dissolve the morphine tartrate in sufficient recently boiled and cooled distilled water to produce 1100 minims of the injection.

The use of morphine tartrate in place of the acetate, formerly directed, is a decided improvement, as solutions of the latter salt spoil readily. 11 minims of the solution contain $\frac{1}{2}$ grain of morphine tartrate.

Uses.—Prepare freshly as needed and give subcutaneously in doses of from 1 to 5 minims (0.05–0.30 Cc.).

INJECTIONES HYPODERMICÆ.—Hypodermic Injections.

This class of solutions although still recognized in the British Pharmacopœia, have been entirely replaced in this country by hypodermic tablets for preparing the solution extemporaneously. The tablets when carefully made are more convenient than a ready-made solution and keep much better. They are made by mixing the active medicinal agent with sufficient diluent—cane-sugar, milk-sugar, or sodium sulphate—to produce tablets of the required size, usually $\frac{5}{32}$ inch in diameter and from $\frac{1}{10}$ to $\frac{1}{8}$ inch thick, which are readily soluble in 10 or 15 minims of water previously drawn into the barrel of the hypodermic syringe.

INULA.—Elecampane.

Radix helenii, R. inulæ, R. enulæ.—Alicompane, Elf-dock, Wild sunflower, Velvet dock, E.; *Alantwurzel, Helenenwurzel, Glockenwurzel, Ottwurz,* G.; *Aunée officinale, Grande aunée,* Fr. Cod.; *Enula,* Sp.; *Elenio,* It.; *Enula Campane,* It., Sp., Port.

The dried root of *Inula Helenium* L. (*Corvisartia H.* Merat.; *Aster H.* Scop.—Fam. *Compositæ*).

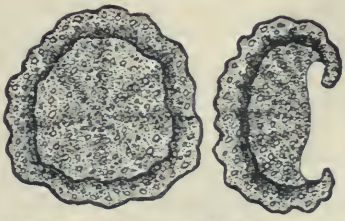
Inula is official in most pharmacopœias. The Belgian describes it as having a violet-like odor.

Origin.—From a large, very stout and coarse perennial herb, native of the temperate regions of Europe and Asia, and thoroughly naturalized in the eastern United States, where it can often be seen abundant in pastures, growing like the Mullein, preferring wet, rocky ground at and near the base of eastern and southern slopes. It produces a radical rosette of enormous ovate, acute leaves, with long margined petioles, somewhat toothed and softly- or velvety-hairy underneath. Those of the stem become shorter and relatively broader, and are clasping. The yellow heads form a loose terminal corymb and resemble small sun-

Fig. 229.

Inula (¾ Nat.).

Fig. 230.



Elecampane root: transverse sections (× 2).

flowers, but the florets have a hairy pappus. The root is supposed to be collected in the fall of the second or the spring of the third year, but there is little uniformity in custom. The thick root-branches are much interlaced and cling tenaciously to a large mass of soil which comes up with them, so that cleansing is difficult, requiring that the root be cup up and separated, and it is often very imperfectly performed.

Description.—Branching irregularly from an enlarged crown, crooked, rarely exceeding 2.5 Cm. (1 In.) in thickness, mostly cut into transverse or longitudinal slices, the latter mostly less than 15 Cm. (6 In.) in length; outer surface dark-brown, or in the smaller roots light-brown, longitudinally, and for the most part rather finely wrinkled; cut surfaces somewhat concave, pale-yellow, becoming gray with long keeping, smoothish, very finely striate, the edges only slightly incurved, thin and sharp; flexible in damp weather, breaking, when dry, with a short, sharp, fleshy fracture, the bark brown, the wood-zone yellow, somewhat radiate; coarsely dotted with resin-cells, the central portion paler; free from starch; odor peculiarly and sharply aromatic; taste bitter, pungent, and somewhat acrid.

Constituents.—Elecampane contains a trace of volatile oil, 2 per cent. of soft acrid resin, a bitter principle, wax, alantic anhydride ($C_{15}H_{20}O_2$), liquid aromatic alantol

($C_{10}H_{16}O$), helenin (C_6H_8O), true alant-camphor, inulin, pseudoinulin, and inulenin. *Helenin* occurs in odorless bitterish crystals. *Alant-camphor* is a white stearopten with a minty odor and taste, and melting at 64° C. (147.2° F.). *Inulin* (*alantin*, $6C_5H_{10}O_5.H_2O$) is a fine white, odorless, tasteless, very hygroscopic powder, resembling starch in appearance, but differing from it in giving a yellow instead of a blue color with iodine, in being soluble in boiling water without forming a paste, and in being deposited unchanged from the hot aqueous solution when it cools. By prolonged heat or the action of dilute acids it is changed first to *met-inulin*, then to *levulin*, and finally to *levulose*, of which it is probably the anhydride. It is only slightly changed to sugar by ferments. Dragendorff found 44 per cent. of inulin in the autumn roots, but only 19 per cent. in the spring, its place being taken by levulin, mucilage, sugar, and several glucosides. Inulin is closely associated in the plant with *inulenin* ($(C_6H_{10}O_5)_{10}2H_2O$), obtainable in microscopical needles, slightly soluble in cold water and weak alcohol, and *pseudoinulin* ($(C_6H_{10}O_5)_{16}.H_2O$), which occurs in irregular granules very soluble in hot water and weak, hot alcohol, only slightly soluble in cold water, and insoluble in cold alcohol.

Action and Uses.—Elecampane was formerly employed as a tonic, stimulant, diuretic, diaphoretic, expectorant, and emmenagogue, but has now largely fallen into disuse. It was recommended in the treatment of chronic pulmonary affections, typhoid states, menstrual disorders, dyspepsia, and chronic skin lesions. Externally applied, it is somewhat rubefacient, and it has been employed as an embrocation in the treatment of sciatica, lumbago, facial and other neuralgias. The internal dose is from 10 to 30 grains (0.60–2 Gm.), either in powder or in decoction.

Allied Drugs.—The leaves of *I. squarrosa* (L.) Bernh. (*Conyza s.* L.; *I. Conyza* DC.), the *Plowman's spikenard* or *Cinnamon root*, *Dürrwurz* or *Conyze*, of Europe, are used for their diuretic and emmenagogue properties, and burned as an insecticide.

Also classed with *Inula*, as possessing similar constituents and properties, are the following: *Pulicaria dysenterica* (L.) Gærtn. (*Inula d.* L.), the *Fleawort*, *Flohkraut* (G.), or *Pulicaire* (Fr.), a woolly European herb, and *Carlina acaulis* L., the *Carline thistle*, *Eberwurz* (G.), *Carline* or *Chardon doré* (Fr.). The root of the latter European perennial herb is used under the name *Radix carlinæ*. It is long, fleshy, about 25 Mm. (1 In.) thick, usually cut lengthwise, deeply wrinkled, and has a rather thin, light-brown bark and a grayish meditullium, with broad medullary rays. Rather large brown-red resin-cells are found in all parts of the parenchyma. It has a penetrating, unpleasant odor and a sweetish, burning, and bitter taste; its principal constituents are a little resin and a volatile oil, to which the odor and taste are due.

IODOFORMUM, *U. S., Br.*—Iodoform.

Iodoformium, P. G.—*Carboneum jodatum*, *Triiodomethane*, *Formyl teriodide*, E.; *Iodure de formyle*, *Iodoforme*, Fr.; *Jodoform Trijodmethan*, G.

Formula, CHI_3. Molecular weight, 390.61.

Iodoform should be kept in well-stoppered bottles in a cool and dark place.

Origin.—Iodoform was discovered by Serullas in 1822, and its composition was determined by Dumas in 1834. It is formed by the action of iodine in the presence of fixed alkalies or alkali carbonates upon alcohol, acetic and other easily saponifiable ethers, aldehyde, acetone, amylene, butyl, capryl, and propyl alcohols, kinic, meconic, and lactic acids, oil of turpentine, and some other compounds (Lieben, 1870). Pure ethyl ether, ethyl iodide, and allied compounds, methyl and amyl alcohol, chloral, chloroform, the fruit acids, lower fatty acids, various aromatic acids, glycerin, and other compounds, according to Lieben, do not yield iodoform under the conditions mentioned above.

Preparation.—For many years either Bouchardat's or Filhol's process was employed in the manufacture of iodoform. The former consists in heating iodine, potassium bicarbonate, alcohol, and water, in a long-neck flask, to between 60° and 80° C. (140° and 176° F.) until the color has disappeared, then adding small portions of iodine as long as these are taken up and decolorized; the mixture is finally set aside for 24 hours and the crystals collected on a filter. About one-third of the iodine is recovered as iodoform, the remainder forming potassium iodide.

Filhol's process insures a much larger yield. Iodine is added in small portions to a warm mixture of sodium carbonate, water, and alcohol, and, after cooling, the crystals

are collected; the filtrate is again warmed, some alkali carbonate added, and a rapid current of chlorine passed through the liquid as long as iodoform is separated, which is again collected and the filtrate made to yield more iodoform by repeating the treatment. The formation of iodoform may be illustrated by the following equation: $C_2H_5OH + I_8 + 6KHCO_3 = CHI_3 + 5KI + KCHO_2 + 6CO_2 + 5H_2O$, alkali formate being probably always produced, together perhaps with ethyl iodide, acetic ether, and other compounds. The result appears to be greatly influenced by the relative proportions of the materials used and the temperature employed.

In 1889 Sulliot and Raynaud devised a process for the preparation of iodoform direct from the ash of sea-weed (kelp), and this is now largely used in France. The ash is lixiviated, the sulphides and sulphites entering into solution are removed, and the amount of iodine present then determined; from the latter the necessary quantity of the other ingredients is calculated, thus a solution of 50 parts of sodium or potassium iodide is prepared, and to it are added 6 parts of acetone and 2 parts of caustic soda in 1000 to 2000 parts of water; finally a dilute solution of sodium hypochlorite is added, drop by drop, as long as iodoform is produced. The yield is about the theoretical quantity according to the following equation: $3NaI + 3NaClO + C_3H_6O = CHI_3 + 3NaCl + NaC_2H_3O_2 + 2NaOH$. Iodoform thus prepared is called by Casthélaz "absolute iodoform," since it is obtained in a state of great purity, without production of free iodine capable of giving rise to iodic compounds.

At present considerable quantities of iodoform are made by subjecting a solution of 50 parts of potassium iodide in 300 parts of water and 30 parts of alcohol to electrolysis, while a constant current of carbon dioxide is passed into the liquid.

Properties.—Iodoform is in small, lemon-yellow, scale-like, hexagonal crystals (microscopically quite characteristic), which have a pearly luster, are somewhat fatty to the touch, and have a strong characteristic odor and a peculiar sweetish and unpleasantly iodine-like taste. It is nearly insoluble in water, but by heating it with water for about 30 minutes to between 80° and 90° C. (176° and 194° F.) a permanent yellow solution is obtained, which, according to Schadewald (1882), contains between 0.5 and 0.7 per cent. of iodine. Iodoform dissolves at 25° C. (77° F.) in 9391 parts of water, to which it imparts its odor and taste, in 46.7 parts of alcohol, and in 5.2 parts of ether (U. S.); in 50 parts (P. G.), 80 parts (Br.) of alcohol at 15° C. (59° F.), in 12 parts (U. S.), about 10 parts (Br. P. G.), of boiling alcohol, in 5 parts (Br.), 6 parts (P. G.), of ether, and, according to Vulpius (1881), in 100 parts of petroleum benzin, in 67 parts of benzene, in 25 parts of oil of turpentine, in 14.3 parts of oil of lavender, in 12.5 parts of oil of cloves, in 11 parts of oil of fennel, lemon, or rosemary, in 7 parts of oil of cinnamon, and in 6 parts of oil of caraway; it is readily soluble in chloroform, carbon disulphide, and fixed oils; the solutions have a neutral reaction to test-paper, but when exposed to sunlight liberate iodine. Iodoform has the specific gravity 2.0, volatilizes slowly on exposure at ordinary temperatures, fuses at about 115° C. (239° F.), U. S., about 120° C. (248° F.) P. G., to a brown liquid, and sublimes partly unaltered, but at a higher heat is mostly decomposed into iodine and hydriodic acid, with a residue of glossy charcoal, which finally burns without residue. Heated with water, it volatilizes with the vapors without decomposition; but when boiled with potassium hydroxide solution a portion of it is decomposed, yielding potassium formate and iodide, and when distilled with alcoholic solution of potassium hydroxide an oily liquid of an ethereal odor and containing iodine is obtained in the distillate. On digesting about 0.1 Gm. of iodoform with 5 Cc. of an alcoholic solution of potassium hydroxide (1 in 20), and after adding 2 Cc. of chloroform, followed by chlorine-water, cautiously, drop by drop, with constant agitation, the chloroform should be colored violet.

Iodoform contains 96.69 per cent. of its weight of iodine, and the amount present in any of its preparations may be estimated gravimetrically with silver nitrate solution, insoluble silver iodide being formed: $CHI_3 + 3AgNO_3 + H_2O = 3AgI + 3HNO_3 + CO$ — 390.61 grains of iodoform requiring 506.07 grains of silver nitrate for complete decomposition and yielding 699.06 grains of silver iodide.

The odor of iodoform in mixtures and ointments is unpleasant, and may be disguised by the addition to 1 ounce of from 3 to 5 drops of oil of peppermint; Peru balsam, cumarin, the oils of fennel, anise, and others, have also been recommended. The odor adheres persistently to the vessels in which preparations of iodoform have been made, but may be removed by a few drops of oil of turpentine followed by soap and water.

Impurities are not likely to be present; the physical properties, and particularly its odor, behavior to solvents, neutral reaction, and complete volatility, determine the absence of impurities which might result from the process of manufacture. Fixed impurities would be left behind on heating a portion upon platinum-foil until the charcoal has been consumed. "On being dried over sulphuric acid to remove water, the loss in weight should not exceed 1 per cent. If 2 Gm. of iodoform be thoroughly shaken with 10 Cc. of water, the filtrate should be colorless and free from bitter taste (absence of soluble yellow coloring-matters, picric acid, etc.), should not affect the color of litmus-paper (absence of free acids), and should not be rendered more than faintly opalescent by silver nitrate test-solution (absence of soluble iodides)."—U. S.

Pharmaceutical Preparations.—Aromatized Iodoform, N. F.; Compound Powder of Iodoform, N. F.; Iodoform Ointment, U. S. P.; Iodoform Collodion, N. F., Iodoform Gauze, N. F.

Action and Uses.—Iodoform was at one time very largely employed as a local antiseptic in the dressing of wounds, burns, and other solutions of continuity; but investigation has shown that it possesses little antiseptic power on dry surfaces, and acts only when it is decomposed by moist organic matter. Even under these circumstances it is not a very powerful germicide. At the present time its surgical use has become very limited, although it is regarded as being perhaps the best local antiseptic which can be used when there is tubercular infection. Many surgeons still employ it in the form of iodoform gauze in the dressing of sinuses and deep wounds, but still others believe that they get equally good results, when the sinuses are non-tubercular, by the use of plain aseptic gauze. It is not safe to apply more than a drachm of the powdered iodoform over a large broken surface, as cases are on record in which serious poisoning has followed its absorption under these circumstances. Where, however, there are induration of the underlying tissues and low vitality, larger amounts than this may be used without danger of absorption. As already stated, it is in tubercular lesions that iodoform finds its greatest use as an antiseptic. Injected into cavities formed by tubercular abscesses after they have been drained, it is a most efficient form of treatment, and it is largely used in tubercular joint-affections.

Iodoform is also largely used as a dressing for syphilitic sores, particularly in tertiary syphilis, and when made into a fine powder is often puffed into the larynx in laryngeal tuberculosis. Fissure of the anus and inflamed hemorrhoids may be temporarily relieved by a 5-grain suppository of iodoform, because of the local anæsthesia produced in the mucous membrane by the drug.

Many gynecologists use iodoform gauze, iodoform ointment, or iodoform tampons for local alterative effect in subacute or chronic inflammations of the pelvic organs.

Iodoform is employed internally for chronic gastric catarrh, and for catarrh of the duodenum and hepatic ducts, with asserted advantage. The dose is from 1 to 3 grains (0.06–0.20 Gm.), in pill-form.

The symptoms of poisoning produced by the absorption of iodoform from surgical dressings may occur in several forms. If the poisoning is mild, there may be a general feeling of wretchedness, with headache and vomiting; while if it is more severe, there may be cerebral excitement, rapid pulse, disturbance of thought, and anorexia; in still more grave cases convulsions and active delirium followed by coma may develop. The urine is usually scanty or suppressed; and if the poisoning is severe, fatty degeneration in various organs may ensue. The onset of the poisoning may be sudden, and may occur several days after the iodoform has been applied. The treatment of iodoform-poisoning consists in the use of full doses of sodium bicarbonate to aid in the elimination of the iodine, the employment of alcoholic stimulants, copious draughts of water to flush the kidneys, the use of saline infusion, and the application of artificial heat if the temperature of the body falls. Sometimes iodoform may produce a rash on the skin resembling that of scarlet fever.

Derivatives and Allied Products.—Diiodoform. *Tetraiodoethylene.* C_2I_4.—Prepared by the action of iodine on silver acetylide, whereby acetylene diiodide is formed, to a solution of which in carbon disulphide the necessary amount of iodine is then added. After recovery of the carbon disulphide by distillation, the residue is crystallized from benzene. Its formation is indicated by the following equations: $C_2Ag_2 + I_4 = 2AgI + C_2I_2$; $C_2I_2 + I_2 = C_2I_4$. Diiodoform occurs as yellow faintly aromatic crystals, insoluble in water, difficultly soluble in alcohol and ether, but soluble in chloroform.

ANTISEPTOL. *Cinchonine-iodosulphate. Cinchonine herapathite.*—This compound was added to the list of iodoform-substitutes by Yvon in 1891. It is prepared by adding a solution of 25 Gm. of cinchonine sulphate in 2000 Cc. of water to a solution of 10 Gm. each of iodine and potassium iodide in water; the resulting precipitate is washed with water and dried at a moderate heat. Antiseptol occurs as a light powder of reddish-brown color, insoluble in water, but soluble in alcohol and chloroform. It contains about 50 per cent. of iodine, and its chemical formula is uncertain, varying with the mode of preparation.

ANTISEPTIN. *Borothymol zinc-iodide.*—Although claimed by the originator, Dr. Radlauer, to be of a definite chemical composition, antiseptin has been shown by Goldmann to be simply a mixture of zinc sulphate 85 parts, zinc iodide 2.5 parts, thymol 2.5 parts, and boric acid 10 parts.

EUROPHEN. *Diisobutylorthocresoliodide.* $C_{22}H_{29}O_2I = C_4H_9OCH_3C_6H_3C_6H_2.C_4H_9CH_3OI$. Molecular weight, 448.68.—This compound is prepared in a manner analogous to aristol, except that isobutylorthocreosol is used in place of thymol. It is an amorphous yellow powder, of a slightly saffron-like odor, insoluble in water and glycerin, but readily soluble in alcohol, ether, chloroform, and fixed oils. It contains 28.06 per cent. of iodine. It is permanent when dry, but when moistened with water splits up into iodine and a new soluble iodine compound; alkali hydroxides and carbonates likewise liberate iodine. Europhen fuses at 110° C. (230° F.), forming a clear brown liquid. It is 5 times as bulky as iodoform.

LOSOPHANE. *Triiodometacresol.* $C_6HI_3OH.CH_3$.—Introduced in 1892. It is prepared by adding an aqueous solution of iodine and potassium iodide slowly and with constant stirring to a solution of orthooxyparatoluic acid in sodium bicarbonate and water; after 24 hours the triiodometacresol will have separated, and may be washed with water and recrystallized from alcohol. Losophane occurs as colorless, odorless, needle-shaped crystals, which are almost insoluble in water, very difficultly in alcohol, but readily in ether, benzene, and chloroform, and at 60° C. (140° F.) also in fixed oils. It contains 78.39 per cent. of iodine, and melts at 121.5° C. (250.7° F.). Losophane is soluble in dilute sodium hydroxide solution without decomposition, but is decomposed by concentrated sodium hydroxide solutions with the formation of a greenish-black compound insoluble in alcohol.

SOZOIODOL. *Sozoiodolic acid. Diiodoparaphenolsulphonic acid.* $C_6H_2I_2OHSO_3H + 3H_2O$. Molecular weight, 476.25.—This acid and its salts have been especially recommended on account of the large proportions of iodine, phenol, and sulphur present. It is prepared by heating 2 parts of phenol and 1 part of strong sulphuric acid to about 110° C. (230° F.) for 2 or 3 days, whereby paraphenylsulphonic (sozonic) acid is formed. Any excess of carbolic acid is removed, and then iodine is added to form sozoiodolic acid. It contains about 54 per cent. of iodine, 20 per cent. of carbolic acid, and 7 per cent. of sulphur. It is a monobasic acid. The ammonium, lead, mercury, potassium, sodium, and zinc salts of this acid are the agents mostly employed, being recommended as substitutes for iodoform on account of their complete lack of odor; the lithium, aluminum, and magnesium salts have also been prepared. The sodium sozoiodolate, however, is most preferred on account of its ready solubility in water and glycerin (13–14 parts); it occurs in bright, prismatic, needle-shaped crystals. A 3 to 10 per cent. solution in water is found to be most desirable. The solubility in water of these various salts is as follows: the aluminum compound, 3 parts; sodium, 14; magnesium, 16; zinc, 20; ammonium, 30; lithium, 30; potassium, 70; lead, 200; silver, 350; mercury, 500 parts of water.

SULPHAMINOL. *Thioxydiphenylamine.* $C_{12}H_9OS_2N$.—This compound has been especially recommended on account of the absence of odor and taste. Although it is insoluble in water, it is supposed to be decomposed into carbolic acid and sulphur compounds by the digestive fluids. Sulphaminol is prepared as follows: Metaoxydiphenylamine is boiled with sodium hydroxide solution and sulphur; the filtered solution is treated with ammonium chloride, yielding sodium chloride in solution, and a yellow precipitate of sulphaminol which does not combine with ammonia, and which is washed with water and dried. It is a yellow powder, insoluble in water, readily soluble in alkalies, alcohol, and glacial acetic acid. When heated, it turns brown and softens, melting at 155° C. (311° F.). Under the names Sulphaminol—menthol, S. creosote, S. guaiacol, and S. eucalyptol, 8 per cent. solutions of the compound in the different liquids, have been introduced to the medical profession, especially for use in laryngeal tuberculosis.

THIOPHENE. C_4H_4S.—This hydrocarbon was discovered in 1883 by V. Meyer; it occurs in all commercial benzenes, and is isolated by active agitation with concentrated sulphuric acid: it is a colorless, mobile, oily liquid, with a feeble odor, boiling at 84° C. (183.2° F.), and not miscible with water. Thiophene itself has not been used in medicine, but two of its compounds have been successfully employed in Europe. Thiophene diiodide, $C_4H_2I_2S$, has been used as a substitute for iodoform in many surgical cases; it occurs in crystalline plates, is insoluble in water, but soluble in the other usual solvents; it contains about 9.5 per cent. of sulphur, 75.5 per cent. of iodine, melts at 40.5° C. (60° F.), and is volatile at ordinary temperatures. Sodium thiophene-sulphonate, $C_4H_3SNaSO_3$, is a white crystalline powder, containing 33 per cent. of sulphur; it has been used with favorable result in prurigo, proving superior to beta-naphtol, being non-toxic and non-irritating.

IODOLUM, *U. S.*—Iodol.

Tetraiodopyrrol, Pyrrol tetraiodide, E.; *Jodol, Tetrajodpyrrol,* G.

Formula, C_4I_4NH. Molecular weight, 566.17.

A derivative of the base pyrrol, $(CH)_4N$, obtained by direct replacement of hydrogen by iodine in an alcoholic solution of the base, and containing 88.97 per cent. of iodine.

Iodol is the oldest of the iodoform-substitutes, having been introduced by Ciamician and Silber in 1885.

Preparation.—It may be prepared, as stated above, by interaction of iodine and pyrrol in alcoholic solution, when upon addition of water iodol is separated in the form of yellow crystalline flocculi. It can also be obtained by adding a solution of pyrrol in sodium hydroxide solution to a solution of iodine and potassium iodide in water, the resulting precipitate being subsequently washed with water.

Properties.—Pure iodol is a pale-yellow (light grayish-brown, U. S.) bulky powder, more or less crystalline, which should be free from odor and taste. It is soluble at 25° C. (77° F.) in about 4900 parts of water, 9 parts of alcohol, 1 5 parts of ether, 105 parts of chloroform, and in fixed oils. It is soluble in concentrated sulphuric acid, with a green color gradually changing to brown.—U. S. Its alcoholic solution is miscible with glycerin. When heated, iodol remains unaffected up to 100° or 120° C. (212°–240° F.), but is decomposed at a temperature of 140°–150° C. (284°–302° F.), with liberation of violet vapors of iodine. If a mixture of iodol and sodium hydroxide be heated with metallic zinc, vapors of pyrrol will be given off, which will color pine-wood moistened with hydrochloric acid a deep-red color.

Tests.—Iodol when heated in a porcelain capsule should burn without residue (absence of inorganic impurities). 0.5 Gm. of iodol shaken with 100 Cc. of water gives a filtrate which should not be made more than slightly opalescent with silver nitrate test-solution (absence of hydriodic acid or other iodides). 0.5 Gm. of iodol shaken with 100 Cc. of water gives a filtrate which should not communicate more than a light-yellowish tinge to carbon disulphide (absence of appreciable amount of free iodine).—U. S.

Action and Uses.—Iodol possesses the same medicinal properties as iodoform, and because of its less disagreeable odor is sometimes substituted for the latter drug. It has been recommended internally in the treatment of diabetes and tertiary syphilis, and may be used by insufflation in tubercular laryngitis. Externally it has been employed in the treatment of eczema and syphilitic sores, and as an antiseptic dressing for small wounds and abrasions. The internal dose is from 2 to 5 grains (0.12–0.30 Gm.).

IODUM, *U. S., Br., P. G.*—Iodine.

Iode, Fr.; *Jod,* G.

Symbol, I. Atomicity usually univalent. Molecular weight, 125.9.

A non-metallic element, obtained principally from the ashes of seaweeds and from the mother-liquor of Chilian sodium nitrate. Iodine should be preserved in glass-stoppered bottles in a cool place, and be not less than 99 per cent. pure.—U. S.

Origin.—Iodine was discovered in 1811 by Courtois in the ash of seaweeds, and was soon afterward thoroughly investigated by Gay-Lussac; also by Davy, Soubeiran, and others. It is very widely distributed in nature, but is usually met with in small, and even quite minute quantity, almost invariably in combination. The only known occurrence of iodine in the free state in nature is in Woodhall Spa spring at Lincoln, Nebraska, which is colored brown by it. It is found in some minerals combined with mercury, silver, lead, and other metals; in Chile saltpeter, principally as sodium iodate; in many mineral spring-waters, in sea water, in coal, and in many plants and animals living in sea water or near the seacoast. It is often a constituent of the atmosphere in minute quantities, and occasionally of the ashes of some plants growing inland. The soluble iodine compounds of the sea are absorbed and accumulated to a wonderful extent in seaweeds and sponges. The investigations of Vogel, W. Marshall, and Fr. Hundeshagen, in 1895, were the first to give an explanation of this phenomenon, in showing that the iodine is stored in the form of complex carbon compounds. Hundeshagen found 8–14 per cent. of iodine in some sponges, which were rich in iodospongin, an organic com-

pound, classed as an albuminoid substance and yielding tyrosin when decomposed. Gautier (1899) showed that sea water contains no sodium iodide, but that the iodine is in the form of organic compounds to the extent of 2.3–2.4 milligrams per liter, of which 1.8 milligrams are dissolved, the rest suspended. He also showed that iodine exists in the atmosphere, not as iodides, but as organic material in the form of spores.

Since Emminghaus and Reinhold administered the thyroid gland with success in the cure of goiter, E. Baumann has isolated (1895) the active constituent of sheep's thyroid, which is present to the extent of only about 0.2 per cent., and has phenolic properties, being soluble in alkalies and reprecipitated by acids. It is remarkable for its great stability toward boiling 10 per cent. sulphuric acid, its intense physiological action, and, above all, its large amount of iodine, which has led to the names thyroiodine, thyrein, or iodothyrin. A pure sample of thyroiodine gave 9.3 per cent. of iodine. In the market it appears diluted with milk-sugar until it contains 0.03 per cent. of iodine, which is the same as in fresh thyroid glands.

Preparation.—Most of the iodine is now obtained from the mother-liquors of Chile saltpeter in South America, but some is still obtained from *kelp*, which contains about $\frac{1}{224}$ of its weight of iodine. Kelp is the ash left on the burning of seaweeds. The weeds are first dried, and then charred or burned at as low a temperature as possible, to avoid loss of iodine. The ash is exhausted with hot water, and the solution concentrated and cooled to remove by crystallization potassium chloride and sodium carbonate and sulphate. More of the latter salt will crystallize after the addition of sulphuric acid, whereby the sulphides and thiosulphates present are decomposed. To the mother-liquor, heated in lead retorts to a temperature a little over 60° C. (140° F.), manganese dioxide is added in small quantities, when iodine distils over, and is collected in glass receivers, several of which are connected with each other. The liberation of iodine from the sodium iodide of the liquor is explained by the following equation: $2NaI + 3H_2SO_4 + MnO_2 = I_2 + 2NaHSO_4 + MnSO_4 + 2H_2O$, acid sodium sulphate and manganous sulphate being formed at the same time. Improved processes of obtaining iodine from seaweeds have been introduced. One of these consists in charring the dried weeds in retorts to avoid loss of iodine. Another process consists in boiling the weeds with sodium carbonate solution, whereby iodine is extracted. The solution is acidified to precipitate algin and then neutralized and evaporated. The iodine is then liberated.

At Tarapaca, Chile, the mother-liquor from the saltpeter, which contains on an average 22 per cent. of sodium iodate, is treated with the calculated quantity of sulphurous acid, according to the equation: $2NaIO_3 + 5H_2SO_3 = Na_2SO_4 + 4H_2SO_4 + 2I$. The liberated iodine is filtered or distilled off, and sent into market as crude iodine. If it is not feasible to set up the apparatus on the spot for distilling off the iodine liberated as just described, it is reduced further to hydriodic acid by means of sodium sulphite or thiosulphate, and then converted into insoluble cuprous iodide by adding copper sulphate; thus, $2HI + H_2SO_3 + 2CuSO_4 + H_2O = 2CuI + 3H_2SO_4$. Cuprous iodide offers a convenient form for shipment. It is not employed to yield free iodine, but alkali iodides.

Purification.—In the crude state iodine is chiefly contaminated with water, but it sometimes contains also cyanogen iodide, and occasionally iodine chloride, ICl, and iodine bromide, IBr. The iodine is dried as much as possible by mechanical means and then mixed with potassium iodide and sublimed. The first portion is rejected as containing some possible cyanogen iodide, which is easily volatilized, after which sublimation is continued. The potassium iodide decomposes ICl and IBr; thus, $KI + ICl = KCl + 2I$. The product is the resublimed iodine of commerce. Iodine absolutely free from chlorine and bromine may be obtained by distilling a mixture of potassium iodide and a concentrated solution of ferric ammonium sulphate. Iodine is liberated by the ferric sulphate and sublimes.

Properties.—Iodine is in flat, scale-like rhombic crystals of a grayish-black or bluish-black color and a bright metallic luster, in thin splinters transparent with a red color. It is soft and friable, and has a peculiar odor, suggestive of chlorine, and a very caustic and acrid taste. The skin or paper is colored red-brown to dark-brown, the stain disappearing gradually. Iodine has neither an acid nor alkaline reaction, but slowly destroys all vegetable colors. It has the specific gravity 4.95, vaporizes slowly and without residue at ordinary temperatures, fuses near 115° C. (239° F.), congeals at 113.6° C. (236.5° F.), and boils above 175° C. (347° F.), according to Stas, when

quite pure at 250° C. (482° F.); its vapor has the density 8.7, and a reddish or purple, or above the boiling-point a deep-blue color. Iodine dissolves with a brown-yellow color in about 60 parts of glycerin, and in 7000 parts (Gay-Lussac) (5000 parts, according to U. S. P.) of water, and forms with it gradually hydriodic acid, which dissolves more iodine; its solubility in water is also increased by tannin and by many salts, and particularly by iodides. It requires for solution about 10 parts of alcohol at 25° C. (77° F.), and dissolves freely in ether, both solutions having a brown color; it is easily soluble in chloroform, carbon disulphide, benzene, and other hydrocarbons, with a purplish or violet color.

Iodine is readily recognized by the blue color which it imparts to starch-paste, by which test $\frac{1}{400000}$ part of free iodine is recognized. Water containing traces of free iodine will yield it to carbon disulphide, etc., in which solution it is recognized by the purplish color and by the blue color produced with starch-paste. Iodine in combination must previously be liberated by chlorine gas, avoiding an excess of the latter, or, if present as iodate, sulphurous acid or other deoxidizing agent will set it free.

Impurities and Adulterations.—At present iodine is usually met with in commerce in a very pure condition, containing but minute quantities of impurities. An excessive proportion of water is indicated by the iodine adhering to the bottle, and may be removed by placing it under a bell-glass over oil of vitriol at a low temperature; moist iodine yields with benzene or chloroform a turbid solution, from which the water gradually separates, the solution becoming clear. Iodine cyanide and iodine chloride are rather freely soluble in water, and their solutions dissolve iodine with a brown color; they may be separated by heating the iodine in a suitable apparatus for about 15 minutes to 100° C. (212° F.) and cooling the vapors well; the former impurity will sublime as white or yellowish needles, the latter as hyacinthe-red prisms or red-brown oil; both have a pungent odor. For their detection the following processes are given: If 0.5 Gm. of iodine be triturated to a fine powder, then shaken with 20 Cc. of water for a few minutes, the liquid filtered, and to one-half of the filtrate, contained in a test-tube, decinormal sodium thiosulphate solution carefully added until the liquid becomes discolored, then a few drops of solution of ferrous sulphate and subsequently a little sodium hydroxide test-solution added, and the mixture gently heated, on finally adding a slight excess of hydrochloric acid the liquid should not assume a blue color (absence of iodine cyanide). If to the other half of the above-mentioned filtrate, contained in a test-tube, a slight excess of silver nitrate test-solution be added, and the mixture actively shaken then, after subsidence of the precipitate, the clear, supernatant liquid be carefully and completely decanted, and the precipitate shaken with a mixture of 1 Cc. of ammonia water and 9 Cc. of water, the filtered liquid, after the addition of a slight excess of nitric acid, should not become more than slightly opalescent (limit of chlorine or bromine).—U. S. The following is the same test somewhat modified: If iodine be dissolved in sulphurous acid, the solution strongly supersaturated with ammonia, and completely precipitated by silver nitrate, the filtrate, on being supersaturated with nitric acid, should not at once become more than faintly cloudy (absence of more than traces of bromine or chlorine). The amount of pure iodine present is estimated volumetrically as follows: Place about 0.5 Gm. of iodine (1 Gm., Br., 0.2 Gm., P. G.) in a tightly-stoppered weighing-bottle and weigh accurately; add 1 Gm. of potassium iodide (2 Gm., Br. P., 1 Gm., P. G.), and dissolve in 50 Cc. of water (50 Cc., Br., 20 Cc., P. G.); then add tenth-normal sodium thiosulphate solution until the liquid is decolorized; The number of Cc. of tenth-normal sodium thiosulphate solution consumed, when multiplied by 1.259 (0.01259×100), and divided by the weight of the iodine taken, gives the percentage of pure iodine present. —U. S. The Br. P. requires in the above test 78.4 Cc. and the P. G. 15.6 Cc. of tenth-normal sodium thiosulphate solution, indicating respectively 98.7 and 98.94 per cent. of pure iodine. The reaction taking place during titration is: $2I + 2Na_2S_2O_3 = 2NaI + Na_2S_4O_6$. Owing to the fact that the pharmacopœias adopt different atomic weights for iodine, 1 Cc. of tenth-normal thiosulphate is equivalent to 0.012685 Gm. of iodine (P. G.), 0.01259 Gm. of iodine (Br., U. S.).

Fixed impurities, such as graphite, charcoal, sawdust, metallic compounds, etc., are left behind on volatilizing a little iodine from a porcelain dish.

Pharmaceutical Preparations.—Carbolized Solution of Iodine, Churchill's Tincture of Iodine, Decolorized Tincture of Iodine, N. F.; Compound Solution of Iodine, U. S. P.; Iodine Caustic, Iodine Liniment, Iodized Carbolic Acid, Iodized Collodion, Iodized Starch, N. F.; Tincture of Iodine, Ointment of Iodine, U. S. P.

Action and Uses.—When iodine is applied to the skin in concentrated form, in ointment or in alcoholic solution, it produces a sense of warmth in the part, which may increase in degree till it amounts to a painful burn, causing redness and swelling of the part and adjacent tissues. The tincture stains the skin a brownish-yellow; or if it has been applied freely, a brownish-black. A considerable amount of this discoloration disappears as the drug is volatilized by the heat of the body if the application has been a mild one; but if it has been severe, a large part of it remains. A very small quantity of iodine is absorbed through the skin unless the epiderm is broken. In one instance in which a colored boy was painted with tincture of iodine from the knees to the ankles, acute poisoning ensued 24 hours afterward; the symptoms consisting of headache, of pain over the kidneys and in the bladder, followed by vomiting, thirst, suppression of urine, priapism, and hiccough. The stools became bloody, and death occurred from exhaustion 6 days later. There are a few other instances in which small areas of unbroken skin have seemed to absorb iodine in sufficient quantity to produce systemic symptoms, but this occurrence must be considered a rare one. When the epiderm is broken, iodine is rapidly absorbed through the skin. The vapors of iodine, when inhaled, act as a stimulant, and then as an irritant to the mucous membrane, and cause headache, coryza, lachrymation, and general respiratory irritation. The drug is eliminated from the body in practically all the secretions, particularly if a sodium or potassium salt is given simultaneously, when it escapes in the form of a soluble iodide.

Iodine is employed externally as a counterirritant over deep-seated inflammations and to cause the absorption of abnormal fluids in synovial membranes. Under these circumstances it is wise to apply several coats of tincture of iodine with a camel's-hair brush, and to repeat the application every day till signs of desquamation of the epiderm or slight tingling is produced, when the applications should cease till the skin is once more able to stand the application of the drug. Should too much iodine be inadvertently applied, the part may be washed with alcohol and a starch poultice placed over it, since starch is the antidote.

Taken internally, iodine, both in substance and solution, acts as an intense gastro-intestinal irritant, and so produces vomiting, diarrhœa, and collapse. But it is a noteworthy fact that while the symptoms are often of the greatest possible severity, death has rarely occurred from this accident. It is possible, however, when death does not ensue as a result of the acute gastro-enteritis for the patient to die of the secondary fatty degeneration in the various organs of the body which is produced by the iodine.

Internally, iodine has been used in the free state to a limited extent. Some practitioners have strongly recommended its use in the dose of 2 or 3 minims (0.10–0.20 Cc. of the tincture 3 times a day in the treatment of typhoid fever and intermittent fevers, but this use of it has become obsolete. Iodine as iodine is very seldom given internally. Perhaps its most common use is in the dose of ½ to 1 minim (0.025–0.05 Cc.) of the tincture with the same quantity of carbolic acid in a little water in the treatment of obstinate vomiting.

At one time tincture of iodine was largely employed in the cure of hydrocele. After the fluid had been evacuated, the pure tincture was injected directly into the sac. This method of treatment has now been largely displaced by more modern and less painful methods.

The best antidote for a poisonous dose of iodine is starch mixed with warm water; white of egg and milk are also advantageous. Sodium bicarbonate may also be given freely. The stomach should be washed out by means of a stomach-tube or emptied by means of emetics, and after this viscus has been thoroughly rid of the poison opium should be given to relieve pain and quiet the patient.

Various preparations of iodine are more commonly used in internal medicine than is iodine itself, as, for example, Lugol's Solution (see Liquor Iodi Compositus) and Donovan's Solution (see Liquor Arseni et Hydrargyri Iodidi).

COMPOUNDS OF IODINE.

Iodine combines in several proportions with oxygen, the most important compound being **iodic acid**; it unites with hydrogen to form hydriodic acid, and combines with most of the other elements and with many organic compounds.

The **iodides** of the metals are partly crystallizable, and are either white or not infre-

quently of a bright color. With the exception of those of gold and allied metals, they are mostly not decomposed by heat, except in contact with air or with oxidizing agents. The alkali iodides are more volatile than the corresponding chlorides, and on being heated with calcium sulphate in the air evolve iodine, while alkali sulphate and calcium oxide remain. The iodides are decomposed by chlorine, bromine, nitric acid, and strong sulphuric acid, and on being heated with acid sulphates. Most of the iodides are soluble in water, and these solutions are precipitated dingy white by cuprous and cupric salts, the latter liberating a portion of the iodine; bright-yellow by lead salts; brown by bismuth salts; green-yellow by mercurous salts; scarlet-red by mercuric salts; yellowish-white by silver salts; yellow or green by gold salts; black with palladium salts; and dark-brown by platinum salts, the solution acquiring at first a deep brown-purple color. The valence of iodine is variable; in hydriodic acid and iodides it is univalent, while in iodic acid, chloride and bromide of iodine, and some other compounds, it is evidently trivalent or pentavalent.

Iodi Bromidum. *Bromide of iodine, Iodine pentabromide; Bromure d'iode,* Fr.; *Jodbromid,* G. IBr_5.—Iodine pentabromide is prepared by dissolving 20 parts of iodine in 63 parts of bromine, and heating the solution for some time in a large flask to about 60° C. (140° F.) until it yields a clear solution with 6 or 8 parts of water. It is a dark reddish-brown liquid, resembling bromine in appearance and sensible properties, but yielding a perfectly transparent brown-red solution with less than 6 parts of water. In the presence of a small quantity of water and at a low temperature the hydrate crystallizes in brown-yellow needles or prisms, melting again at 4° C. (39.2° F.), with separation of water. A solution containing 15 per cent. of the bromide is found in commerce. When the compound is kept for some time at or above 63° C. (145.4° F.), the boiling-point of bromine, a portion of the latter distils off, and iodine monobromide, IBr, is left as a dark-brown sublimable crystalline mass. Iodine tribromide, IBr_3, may be prepared by using only 37.8 parts of bromine for every 20 parts of iodine. The pentabromide is used locally in diphtheria in solution of 2 drops to a fluidounce of mucilage.

Iodi Chloridum. *Chloride of iodine. Iodine trichloride,* E.; *Chlorure d'iode,* Fr.; *Jodtrichlorid, Dreifach-Chlorjod,* G. ICl_3.—If dry chlorine gas be passed over dry iodine, union of the two elements takes place, a liquid results, and iodine monochloride will have been formed; the reaction is ended when the iodine has acquired the calculated increase in weight. ICl_3 is a reddish-brown liquid which in the course of time deposits crystals melting at 25° C. (77° F.). If the process be somewhat modified, so that dry iodine be sublimed in vessels containing a constant excess of dry chlorine gas, iodine trichloride will be formed as orange-yellow needles having the specific gravity 3.11, and gradually changing to large transparent rhombic plates. It has a penetrating, pungent odor, resembling bromine; when heated to 25° C. (77° F.) it liquefies and is decomposed, chlorine being given off and iodine monochloride formed. Iodine trichloride is soluble in 5 parts of water, and also in alcohol and ether; a concentrated aqueous solution keeps well, but a diluted aqueous or an alcoholic solution gradually changes even in the cold, forming iodine monochloride, iodic acid, and hydrochloric acid. If concentrated sulphuric acid be added to a strong aqueous solution, a white curdy precipitate will form, which is iodine trichloride, and soon assumes the characteristic orange-yellow color. Iodine trichloride contains 54.39 per cent. of iodine and 45.61 per cent. of chlorine, and has been employed internally in doses of about $\frac{1}{6}$ grain and externally in aqueous solution (0.1–0.2 per cent.) as lotion or injection.

Iodo-tannin.—It has long been known that iodine dissolves in solutions of tannic and gallic acids, forming reddish-brown liquids in which free iodine can no longer be detected by starch-paste. Until recently the view prevailed that the iodine entered into chemical combination with tannin, and the name iodo-tannin was given to this compound as early as 1854. Formulas have been repeatedly published for preparing a syrup, tincture, and wine of iodo-tannin, and these preparations have been used to some extent, especially in France. Power and Shedden (*Pharm. Jour.*, Aug. 5, 1901) have shown that true or definite compounds of iodine with either tannic or gallic acid cannot be formed by the simple interaction of these bodies in the presence of water, for under these circumstances the iodine acts simply as an oxidizing agent. The resulting products, therefore, contain the iodine in the form of hydriodic acid associated with unaltered tannic or gallic acid and the oxidation-products of the latter.

IPECACUANHA, *U. S.*—Ipecac.

Ipecacuanhæ radix, Br. P.; *Radix ipecacuanhæ,* P. G.—*Ipecac,* E.; *Ipécacuanha annelé (officinale)* Fr. Cod.; *Radix Cephaëlidis,* Nor.; *Brechwurzel, Ruhrwurzel,* G.; *Racine brésilienne,* Fr.; *Ipecacuanha officinal, Bejuquillo,* Sp.; *Hippo, Cipo Emetico, Poaya Verdadera,* Port.

The dried root, to which may be attached a portion of the stem not exceeding 7 Cm. in length, of *Cephaëlis Ipecacuanha* (Brotero) A. Richard (*Callicocca I.* Brotero; *Psy-*

chotria I. Stokes; *C. emetica* Pers.; *Ipecacuanha officinalis* Arruda; *Uragoga I.* Baillon. —Fam. *Rubiaceæ*), known commercially as *Rio, Brazilian,* or *Para Ipecac,* or the corresponding portion of *C. acuminata* Karsten, known commercially as *Carthagena Ipecac,* yielding, when assayed by the process given below, not less than 2 per cent. of ipecac alkaloids.

Ipecac is official in all pharmacopœias, and all but the Italian restrict it to the root first named above, though various synonyms are employed by them in naming it. The British calls it *Psychotria,* on the ground that the establishment of this name was prior to that of *Cephaëlis;* but this claim is without weight, since the structure of the plant excludes it from the genus *Psychotria.* The German calls it *Uragoga,* because that name was established by Linné as early as 1737; but in accordance with the agreement, now almost uniform, that botanical nomenclature shall not date from any period prior to the year 1753, the first name used upon or after that date must be adopted, and "*Uragoga*" was not employed until 1867–69, when it was taken up by Baillon. In the meantime (1788), the name *Cephaëlis* was established for the genus by Swartz. In 1805 Brotero named the Ipecac plant *Callicocca Ipecacuanha,* in disregard of the generic name already established, and Richard subsequently transferred the specific name *Ipecacuanha* to its proper connection with Cephaëlis. The Italian Pharmacopœia specifies the Carthagena variety, named above. The Swedish Pharmacopœia directs that roots denuded of bark are to be rejected. Most pharmacopœias specify that only the bark is to be included in the powder. Several regard the rejected wood as amounting to about 25 per cent., one (the Swiss) to but 15 per cent., a question which will be found discussed under *Constituents.* The Russian provides that in decoctions and infusions the entire root may be used.

Origin.—The Brazilian Ipecac plant is rather widely distributed through Brazil and adjacent Bolivia, and the drug is chiefly collected in the vicinity of the Itenez River, whence it is exported, either southeastward *via* Rio Janeiro, or northeastward *via* Para. The plant is a low, straggling, soft-wooded shrub, growing in rich forest-loam, the base of the stem partly prostrate and more or less covered with vegetable débris. This habit of growth results in a sharp distinction between the lower and upper portions of the stem, this lower portion being quite largely collected with the root, such a product being designated commercially as "stemmy." Its relative quality is discussed under *Constituents.* The bulk of the crop is gathered between January and March, when the ground is soft. The roots are torn up by means of a curved and sharpened stick. The irritating character of the plant-juice results in the production of sores upon the hands, and even upon other parts of the bodies of the collectors, so that the labor is highly objectionable, the natives only engaging in it when other work, such as rubber-gathering, is unobtainable. The high price of the drug is largely due to this cause. The drug is dried in the sun, often imperfectly, and is then packed very tightly in hide-bound bales, called *serons.* Storage of the bales is careless and continues until chance traders visit the region. Subsequent transportation is subject to great vicissitudes of weather and exposure to river-water, so that moulding of the root is of the most common occurrence. It is estimated that the contents of about 75 per cent. of the imported serons are damaged by mouldiness or otherwise by water. Little is known regarding the Carthagena Ipecac plant and its collection. Various attempts to cultivate Ipecac have been made in India, but with little success, owing apparently to a lack of adaptability to soil and climate. Ipecac grown at Johore, Straits Settlement, is practically equal in appearance and quality to that from Brazil.

Description.—*Rio Ipecac.*—In pieces of irregular length, rarely exceeding 25 Cm.; stem portion 2 to 3 Mm. thick, light gray brown, cylindrical, and smoothish; root portion usually red brown, occasionally blackish brown, rarely gray brown, 3 to 6 Mm. thick, curved and sharply flexuous, nearly free from rootlets, occasionally branched, closely annulated with thickened, incomplete rings, and usually exhibiting transverse fissures with vertical sides through the bark; fracture short, the very thick, easily separable bark whitish, usually resinous, the thin, tough wood yellowish white, without vessels; odor very slight, peculiar, the dust sternutatory; taste bitter and nauseous, somewhat acrid.

Carthagena Ipecac.—Is similar to Rio Ipecac, but about one-half thicker, dull gray externally, with thinner, merging annulæ, and the fracture-surface of the bark gray.

The stem-portions should show no marked indications of having been leaf-bearing, such an indication applying to portions which have been exposed to light and air, which

would probably tend to decrease the alkaloidal percentage. Ipecac in which the bark is very thick as compared with the woody centre is denominated "fancy" or "bold," while that in which the woody centre is relatively thick is denominated "wiry."

The powder of Ipecac is of a light brownish gray. Under the microscope, its characteristic elements are seen to be chiefly thin-walled parenchymatic cells containing an abundance of starch, the grains mostly compound, and usually of 2 to 4 units, the single ones mostly less than 10 mikrons in diameter. Bundles of needle-shaped crystals, or the scattered crystals, are common. Thin-walled cork-cells are rather abundant, as well as tracheids bearing numerous small pores. Wood-fibres should be nearly or quite absent.

Fig. 231.

Ipecacuanha.

Fig. 232.

Striated ipecacuanha.

Fig. 233.

Undulated ipecacuanha.

The presence of large, rather thick-walled pith-cells indicates a more or less stemmy quality of drug.

Ipecac root grown in the East Indies has been noted as exhibiting a much greater number of delicate rootlets than the Brazilian.

Damaged Ipecac, as indicated under *Origin*, is very common. It is frequently washed for the purpose of improving its appearance and then dried, the latter process usually imparting a smoky odor to it. By this process, much of the bark is caused to peel off; but by subsequent garbling it is easy to obtain an article which, to the uninitiated, presents an even better appearance than the natural, notwithstanding that it is almost uniformly deficient in alkaloid.

When Rio Ipecac only was official, the Carthagena variety was sometimes garbled and stained to resemble it, and was imported for it.

Several pharmacopœias specify that the aqueous infusion of Ipecac should yield a copious precipitate with Mayer's Solution; the German, that hydrochloric acid with which the root has been shaken should turn blue on the addition of an aqueous solution of iodine, or intensely red on being sprinkled with chloride of lime; the Swiss, that picric acid turns the hydroalcoholic infusion opaque and produces a yellow precipitate, and that the addition to such an infusion of dilute hydrochloric acid, with a little potassium chlorate, colors it orange-red, with reddish fluorescence.

Substitutes and Adulterants.—A very large number of drugs share the emetic and nauseating-expectorant properties of Ipecac, and have been proposed as substitutes for it (see *N. Y. Med. Jour.*, Feb. 11, 1893). Most of these, like the Spurges, Gillenia, Cocillana, Naregamia, and Asclepias, are considered elsewhere in this work. Many others, most of them also resembling Ipecac in properties, have been employed as adulterants, because of their resemblance to it in appearance, and because of the general term "Poaya" being applied in Brazil to plants possessing such properties.

The most important adulterant and substitute is *Undulated* or *Farinaceous Ipecac*, the root of *Richardia scabra* L. (*Richardsonia s.* St. Hil.; *Richardia pilosa* R. et P.;

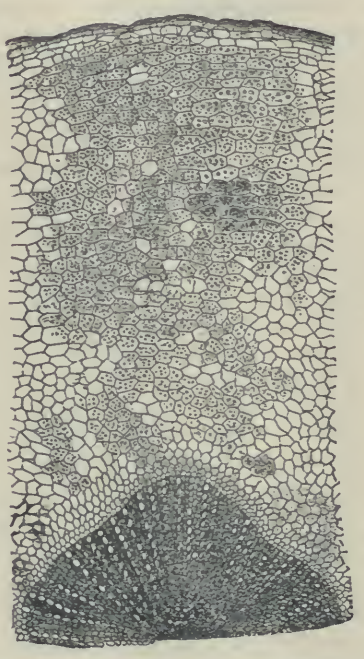
Richardsonia p. H. B. K.), a low herb, in the same family with Ipecac, very widely distributed and abundant in tropical and subtropical America. The root is vertical, often with several small, usually parallel, branches from near the crown, waving or flexuous, tapering gradually, of a pale gray-brown color, usually marked alternately on the sides with sharp constrictions, which pass only part of the way around. Its bark is thick, like that of Ipecac, and of a white fracture. The wood is softer and weaker than that of Ipecac, and is porous and of a yellowish color. This root has also been used to adulterate Senega. A somewhat similar form of it, known as *Small Striated Ipecac*, is referred to the same genus. Both contain a principle very similar to, if not identical with, emetine, and are emetic.

Large Striated Ipecac, or *Black Striated Ipecac*, is the root of *Cephaëlis emetica* Mutis, of the Andean region. The greater portion of its surface is of a dark-brown or even blackish color. It is less crooked than Ipecac, about as large as large Carthagena samples, longitudinally striate, and with scattered deep constrictions or fissures. The bark-fracture is similar to that of the Carthagena, but even darker, and often purplish brown or gray.

The root of *Cephaëlis tomentosa* Vahl. is somewhat employed in tropical America, where it is very widely distributed. It is little constricted, somewhat striate, of a dark gray brown, and its bark is not nearly so thick as that of Ipecac. Various other species of Cephaëlis are also more or less used, especially *C. violacea* Willd.

The term *White Ipecac* is applied to what appears to be the roots of several species of *Ionidium* (Fam. *Violaceæ*), especially to those of *I. Ipecacuanha* Vent., of Brazil, and apparently from other parts of tropical America. It is crooked and irregularly branched. Externally, it resembles Ipecac in its constricted and fissured character, but is larger and much lighter colored. Internally, it bears little resemblance, being more starchy and radiate, and with a thin bark. Other species of Ionidium reported as similarly employed are *I. microphyllum* H. B. K., *I. parviflorum* Vent., and *I. polygalifolium* Vent.

FIG. 234.



Ipecacuanha root, transverse section (× 65).

Various species of Polygala, especially *P. violacea* St. Hil., *P. caracasana* H. B. K., and *P. angulata* DC., have been reported as similarly employed, but their use appears neither common nor important.

The root of *Heteropterys pauciflora* Juss. has been recently introduced as an adulterant. It rather closely resembles Ipecac, but contains no starch, this being replaced by an inulin-like body.

Constituents.—As to its mechanical elements, the bark of the root of Rio Ipecac is variously estimated to represent from 75 to 90 per cent. of the weight, the remainder consisting of the woody portion. In the stem the percentage of bark is somewhat less. Research Committee "C" of the U. S. P. Revision Committee of 1890 found that the wood represented a little less than 11 per cent. in a first-class article. 13½ ounces of root yielded 8⅞ ounces of No. 60 powder and 3⅜ ounces of No. 80 powder.

A good quality of Carthagena Ipecac has been found to yield 20 per cent. of wood, and 25 ounces of it yielded 8⅛ ounces of No. 60, and 12 ounces of No. 80, powder.

The important constituent from a medical standpoint is the mixed alkaloid considered below. In a root of good quality the alkaloid amounts to between 2 and 3 per cent. All authorities agree that this alkaloid exists to but a very slight extent in the wood, and it appears that in the bark it is most abundant just underneath and in the corky layer. The relative richness in alkaloids of the root and stem has been the subject of much discussion, and the conclusions of different experimenters vary most widely. Dohme has reported that stemmy Ipecac is actually richer than the root in alkaloid; Paul and

Cownley, who have devoted much time to studying the composition of this drug, report the stem as containing about one-third less alkaloid than the root. Attfield found 1.95 per cent. in Ipecac of which 34.3 per cent. was stem, and 1.82 per cent. in one of which 37.4 per cent. was stem. He found the difference in content of alkaloid between root and stem to amount from 0.13 to 0.6 per cent. The probability is that this relation depends largely upon the character of the stem examined. Judging from what we know of other drugs, and from theoretical considerations, that portion of the stem which is excluded from light and air would develop practically as much alkaloid as the root itself, while the production should decrease in the exposed portion. Another question which has received much attention is the relative value of wiry and bold roots. Since it is known that alkaloid is almost wanting in the wood, it would seem almost certain that a bold root would be richer than a wiry one; yet Dohme and Kebler both report the wiry root to be the richer. It is not impossible that this difference may be due to the larger amount of starch existing in the bolder root, and this in turn might be modified by the season of collecting; but this question must be regarded as still unsettled.

The non-alkaloidal constituents of Ipecac are about 40 per cent. of starch; usually some cane-sugar; resin, wax, and fat; a trace of nauseating volatile oil; *erythrocephælin*, a coloring-matter becoming deep-purple with alkalies; and about 2.25 per cent. of *ipecacuanhic acid* ($C_{14}H_{18}O_7$), a glucoside resembling caffeotannic and kinic acids, and which, in the drug, holds the alkaloids in combination. Paul and Cownley regard this acid as a mixture, consisting in part of saponin. It is an irritating substance.

The alkaloids of Ipecac are almost wholly emetine and cephæline, there being present a very small amount of psychotrine, and apparently a trace of a fourth alkaloid. Of the total alkaloid of Rio Ipecac, nearly three-fourths is emetine, and about one-fourth cephaëline, whereas in Carthagena Ipecac Paul and Cownley found only 0.89 per cent. of emetine, against 1.25 per cent. of cephaëline.

Emetine (methyl-cephæline, $C_{15}H_{22}NO_2$) is an amorphous white alkaloid, soluble in alcohol, ether, chloroform, fixed oils, benzene, and acetic acid, slightly soluble in water and hot petroleum ether, and insoluble in alkalies and essential oils. It melts at 69° C. (156.2° F.) and upon exposure to light gradually assumes a yellow color. Emetine forms crystalline halogen salts and nitrate, the acetate and sulphate being amorphous. Commercial emetine is a mixture of alkaloids, sometimes contaminated with resin or ipecacuanhic acid, and varies in color from brownish-gray to brown. *Cephæline* ($C_{14}H_{20}NO_2$) occurs in white silky needles, soluble in alcohol, chloroform, benzene, and caustic alkalies. It is less soluble in ether, but more soluble in boiling petroleum ether than emetine, and may be readily separated from the latter by its solubility in sodium hydroxide solution. Its salts are amorphous. *Psychotrine* is an uncrystallizable alkaloid which is decomposed by light.

If a drop of Fröhde's reagent be applied to emetine on porcelain, a dirty green color is produced, changed to grass-green by hydrochloric acid. Cephæline, in the same way, gives a purple coloration, changing to a Prussian blue with hydrochloric acid. Psychotrine gives a dull purple changing to a green. (*Allan and Scott-Smith.*)

Assay of Ipecac.—The following is the official process for the assay: Introduce 15 Gm. of ipecac, in No. 80 powder, into an Erlenmeyer flask of 250 Cc. capacity, add 115 Cc. of ether and 35 Cc. of chloroform, shake the flask during 5 minutes, and then add 3 Cc. of ammonia water and shake the flask at intervals during half an hour. Now add 10 Cc. of distilled water, shake the liquid until the powder collects in masses, and pour off 100 Cc. of the clear ether-solution into a measuring cylinder. Transfer the latter to a separator, add 10 Cc. of normal sulphuric acid and 10 Cc. of distilled water. Shake the separator moderately during 2 minutes, and when the liquids have separated, draw off the lower solution into a second separator. Repeat the shaking out of the ether-solution with 3 Cc. of normal sulphuric acid and 5 Cc. of distilled water, drawing off the acid solution into the second separator. Repeat the shaking out again, using 10 Cc. of distilled water, and add the aqueous solution to the second separator. Reject the ether in the first separator, introduce a small piece of red litmus-paper into the second separator, add enough ammonia water to render the liquid alkaline, and 25 Cc. of ether, and then shake the separator vigorously during 5 minutes; draw off the alkaline liquid into the other separator, and the ether-solution into a flask. Again shake out the alkaline liquid with 10 Cc. of ether, and, having shaken the separator during 1 minute, add the ether-solution to the liquid in the flask, rejecting the alkaline liquid. Distil the ether from the flask with the aid of a water-bath, and

dissolve the alkaloidal residue in exactly 12 Cc. of tenth-normal sulphuric acid, warming gently on a water-bath if necessary. Then add 5 drops of hematoxylin test-solution and titrate with fiftieth-normal potassium hydroxide solution. Divide the number of cubic centimetres of fiftieth-normal potassium hydroxide solution used, by 5, subtract the quotient from 12 (the 12 Cc. of tenth-normal sulphuric acid taken), and multiply the remainder by 0.0254 and this product by 10, which will give the percentage of alkaloids in the ipecac.—U. S.

Pharmaceutical Preparations.—Fluidextract of Ipecac, Powder of Ipecac and Opium, Syrup of Ipecac, Tincture of Ipecac and Opium, Wine of Ipecac, U. S. P.; Syrup of Ipecac and Opium, N. F.

Deemetinized Ipecac (*Pulvis Ipecacuanhæ Deemetinisatus*) has been used to some extent. While freed from the emetic principles of the drug, it retains its antidysenteric properties, and is prepared by extracting powdered ipecac root with ammoniacal chloroform, acidulating the resulting solution with diluted sulphuric acid, shaking out the alkaloids with water and then adding the chloroformic liquid to the extracted residuary powder, which mixture is finally dried and again powdered.

Action and Uses.—When locally applied, ipecac acts as a counterirritant, and if allowed to remain in contact with the skin for any length of time, causes a vesicular eruption and considerable irritation. In very minute doses it stimulates the gastro-intestinal tract, thereby increasing the flow of the gastric juice and aiding in digestion. Small doses are diaphoretic and expectorant. In large doses ipecac produces nausea, vomiting, muscular relaxation, and profuse bronchial secretion, and it sometimes causes purging. If emetic doses remain in the stomach sufficiently long, the drug produces circulatory depression and diminishes the activity of the spinal cord. Ipecac is eliminated by the skin, kidneys, and gastro-intestinal tract. Ipecac may be employed as an emetic for the purpose of emptying an overloaded stomach, and is particularly useful in removing mucus from the stomach of young children suffering from digestive disorders. Minute doses are sometimes used in treating vomiting due to depression and for the vomiting of pregnancy. It has been employed successfully in the treatment of cholera morbus, choleraic dysentery, and dysentery, It may be given as a sedative expectorant in the early stages of acute bronchitis, and the wine of ipecac in the form of a spray has been recommended in the treatment of chronic bronchitis. A paste made with powdered ipecac when locally applied is said to relieve the pain and swelling caused by the sting of bees, and a 25 per cent. ointment may be used for its counterirritant properties.

As an emetic, powdered ipecac may be given in doses of 20 grains (1.3 Gm.), and repeated in a half hour if needed. To a child the syrup may be given in doses of from 1 to 3 fluidrachms (4–12 Cc.). As a gastric stimulant the dose is from $\frac{1}{6}$ to $\frac{1}{2}$ grain (0.01–0.03 Gm.), every half hour for 6 doses. As a diaphoretic the dose is about 1 grain (0.06 Gm.). The dose of pure emetine as an emetic is $\frac{1}{8}$ grain (0.008 Gm.). The alkaloid is much more nauseating and prolonged in its action than the drug itself.

IRIS.—Iris.

Blue, Water, or Poison flag, Flag lily, Liver lily, E.; *Verschiedenfarbige Schwertlilie, Amerikanischer Schwertel,* G.; *Rhizome d'iris varié, Flambe variée, Glaïeul bleu,* Fr.; *Liria americana,* Sp.

The dried rhizome and roots of *Iris versicolor* L. (Fam. *Iridaceæ*).

Iris is official only in the United States.

Origin.—A perennial herb of swamps or low grounds throughout eastern and central North America, 2 or 3 feet high, with narrow, equitant, sword-shaped leaves, and large, 3-merous, lily-like flowers, blue except for the yellow and whitish markings at the base of the sepals. Owing to similarity of name, as well as of appearance before blooming, this is sometimes mistaken by children for Sweet Flag, or Calamus, which grows in the same localities, with the production of results more or less poisonous.

Description.—Rhizome of horizontal growth, branched, the branches 5 to 10 Cm. (2 to 4 In.) long and 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) thick, cylindrical in the lower half, thence becoming vertically flattened toward the crown, where it is terminated by a circular scar; dark-brown, wrinkled, annulate with the leaf-bases; fracture short, purplish; roots long, slender, simple, crowded near the flattened end; odor peculiar; taste pungent, acrid, and nauseous.

Constituents.—The rhizome contains starch, gum, tannin, oil, 25 per cent. of acrid resinous matter, and possibly an alkaloid (Cressler, 1881). Distilled with water, the

fresh rhizome yields an opalescent distillate, from which separates a white, camphoraceous substance with a faint odor and soluble in alcohol. The resin is soluble in ether, chloroform, and hot alkalies. The oil possesses the taste and smell, but only partly the medicinal activity of the drug.

Action and Uses.—Fresh iris is quite acrid, and if employed internally produces nausea, vomiting, purging, and colicky pains. The dried root is less acrid, and is occasionally employed as an emetic, diuretic, and cathartic. It is believed by some practitioners to be an hepatic stimulant second only to podophyllin, but if given in full dose it may occasion considerable nausea and severe prostration. The dose is from 10 to 20 grains (0.60–1.3 Gm.), either in substance or in decoction. The *irisin* or *iridin* prepared by the "Eclectics" may be given in doses of from 2 to 4 grains (0.12–0.25 Gm.).

Other Species.—Of the 100 species of *Iris*, 22 inhabit the United States, but only 1 of these (*I. Missouriensis* Nutt.) much resembles the official, or has a rhizome likely to be mistaken for it. This grows abundantly in the Southwest, and it is very probable that it will be found to be practically identical in constituents and properties.

IRIS FLORENTINA.—Florentine Orris.

Radix iridis Florentinæ, Radix ireos.—Rhizoma iridis, P. G.; *Orris root*, E.; *Veilchenwurzel, Schwertelwurz*, G.; *Iris de Florence*, Fr. Cod.; *Liria de Florencia*, Sp.

The rhizome of *Iris Germanica* L., *I. pallida* Lam., or *I. Florentina* L. (Fam. *Iridaceæ*), deprived of the periderm.

Origin.—These well-known and very beautiful ornamental plants are natives of the eastern Mediterranean region, extending into northern India and northern Africa, and largely cultivated for their rhizomes in southern Europe, mostly on the mountain slopes. The flowers of the first named are blue, and constitute the European Blue Flag; those of the second are pale-blue, and of the third almost pure white. The rhizomes are gathered in late summer, soaked in water, and the outer bark scraped off, after which they are dried, by a careful process requiring about 2 weeks. The fresh rhizome lacks the fragrance of the dried, the aromatic principle being developed by the curing process.

Description.—Rhizome horizontal, consisting of vertically flattened joints from 5 to 15 Cm. (2 to 6 In.) long, and 2.5 to 4 Cm. (1 to 1½ In.) broad at the summit, gradually tapering below, abruptly contracted at the top into the stem-scar, at either side of which similar joints are given off; white or faintly yellowish externally and internally; marked on the upper side by transverse rows of fibrovascular bundles pertaining to the leaf-scars and underneath by brownish circular root-scars which are crowded toward the upper end; hard and heavy, the fracture irregular, showing a distinct nucleus-sheath close to the surface, which encloses scattered wood-bundles; odor mild, agreeably violet-like; taste farinaceous, afterward bitter and somewhat acrid.

The powder is whitish and exhibits large thick-walled parenchymatous cells containing simple, oval, or ovoid starch-grains with indistinct markings, and slenderly prismatic calcium oxalate crystals.

Commercial Orris represents two principal varieties, namely, *Veronese*, derived from *I. germanica*, and *Florentine*, from the other two species, more especially from *I. Florentina*. The two varieties are well distinguished by the stronger and finer odor of the latter; not so by their external appearance, although the Florentine is commonly somewhat larger and plumper, and with a less rough surface. The larger and finer joints are often turned into pretty forms to be used for ornamental purposes as well as for use by teething babies. The less handsome rhizomes, as well as the chips, are distilled.

Constituents.—Besides a large quantity of starch, some soft brownish acrid resin, a little tannin which is colored green by ferric salts, and a small amount of iridin, described below, Iris yields, when distilled with water, a peculiar fat-like volatile oil, known commercially as *orris butter*. Different authorities state the yield at from 0.1 to 0.8 per cent. It is claimed that this substance does not pre-exist, but is formed during the distillation process. A method for converting it into a liquid oil is that of adding oil of cedar wood to the powdered rhizome before distilling. The fatty oil above mentioned consists principally (about 85 per cent.) of *myristic acid*, together with small amounts of its methyl-ester, oleic acid and its derivatives, and a minute amount of the

ketone *irone* ($C_{13}H_{20}O$), which last constitutes the ultimate odorous principle. *Iridin* ($C_{24}H_{26}O_{13}$) is a glucoside, occurring in white needles, soluble in 500 parts of water and in hot alcohol, insoluble in ether, chloroform, and benzol. It yields *irigenin* ($C_8H_{16}O_8$), which, heated with concentrated alkali, forms *iretol* ($C_7H_8O_4$), *iridic acid* ($C_{10}H_{12}O_5$), and formic acid. Iridic acid yields *iridol* ($C_9H_{12}O_3$).

Action and Uses.—Orris root is rarely employed in medicine at the present time. The fresh root is said to be emetic and cathartic, and if given in large dose to occasion nausea, vomiting, purging, and colic. The dried powder is said to be a sialagogue and sternutatory. Pieces of the root are occasionally chewed for the purpose of overcoming disagreeable odor of the breath, and the powdered drug enters into the composition of many tooth-powders. The drug was formerly employed in the treatment of bronchitis and chronic diarrhœa, and was considered a useful remedy in dropsy. The internal dose is stated to be from 5 to 15 grains (0.30–1 Gm.).

J.

JALAPA, *U. S., Br.*—Jalap.

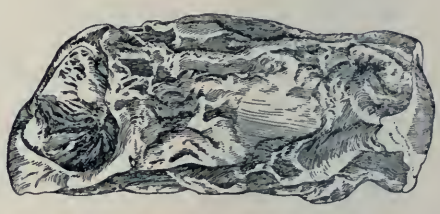
Tubera jalapæ, P. G. (and most pharmacopœias); *Radix jalapæ, Radix Ipomœarum.*—*Jalape, Jalapenknollen*, G.; *Jalap tubéreux J. officinal*, Fr. Cod.; *Jalapa*, Sp.; *Sciarappa, Gialappa*, It.

The dried tuberous root of *Exogonium purga* (Wend.) Benth. (*Convolvulus p.* Wend.; *Ipomœa p.* Hayne; *I. Schiedeana* Zucc.; *I. Jalapa* Schiede et Deppe; *Exogonium J.* Baill.; *E. dumosum* Benth.—Fam. *Convolvulaceæ*).

The first name applied to this plant was "*Ipomœa Jalapa,*" but another species of Ipomœa had previously been called "Jalapa," by Linné, although he placed it in the genus *Convolvulus;* hence the name is not tenable for the Jalap plant, which would give us two of the same name in the same genus.

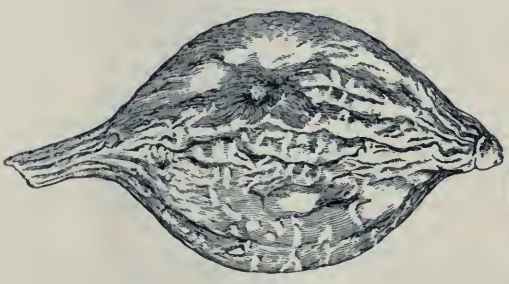
Jalap is official in all pharmacopœias, which differ greatly in the percentage of resin required, this requirement ranging from 7 to from 15 to 18 per cent. The required limitations of solubility of this resin in chloroform

Fig. 235.



Male jalap (Nat.).

Fig. 236.



Jalap: a small tuber.

Fig. 237.

Jalap (½ Nat.): A, showing a starchy, B, a resinous fracture.

range from 6 to 7 per cent.; in ether from "almost insoluble" to 10 per cent. soluble. Either of the two last requirements will exclude the so-called Male Jalap (*Stipites Jalapæ*) and Tampico Jalap. Most pharmacopœias call attention to the fact that the tubers should be heavier than water.

Origin.—The Jalap plant is a perennial twining climber, bearing handsome rose-purple flowers similar to the cultivated Morning-Glory. It is a native of the eastern slopes of the Mexican Andes, flourishing at an elevation of 5000 to 8000 feet, where rain is very frequent and abundant. Its habitat is thus very similar to that of the Cinchona. The drug proceeds chiefly from plants cultivated in their native home. Jalap has also been introduced to culture in other tropical regions, but only in India have any practical commercial results been obtained. The Indian product appears to be inferior to the Mexican. Grown in England and other temperate regions, frost is apt to overtake it before the tubers are matured. In cultivation, the soil must be a rich forest-loam, the fertility of which is quickly exhausted by Jalap cropping. Trellises or other forms of artificial support have to be supplied. The plants should be three years old before cropping is begun, and a crop can be gathered from the same plants each third year thereafter. Natural drying is a long and tedious process, as well as a risky one, and is usually substituted or assisted by drying over wood fires, which process imparts a slight smoky odor to the product, and hydrates much of the starch. Large tubers are often sliced to facilitate drying, but this form is not so highly esteemed. From 3000 to 5000 pounds of fresh jalap are said to be yielded per acre, and this is reduced by about 70 per cent. in drying.

Description.—Napiform, pyriform or oblong, occasionally reaching 3 or 4 inches in diameter, the large ones often incised or sliced; externally, more or less wrinkled, dark brown with lighter-colored spots and short transverse ridges; hard, compact, sinking in water

either before or after being broken open; internally pale grayish brown, with numerous concentric circles consisting of the ends of resin-ducts; fracture resinous, not fibrous nor starchy; odor slight, but peculiar, smoky and sweetish; taste sweetish and acrid.

The dark-brown powder exhibits large quantities of starch, the grains solitary or in masses of 2 or 3, rarely more. The solitary grains range from 10 to 35 mikrons in size (*Jelliffe*). They are mostly rounded, with a slightly eccentric, rarely fissured hilum and moderately distinct rings. Numerous masses of calcium oxalate crystals, mostly about twice the size of the solitary starch-grains, are also seen. The more abundant the starch, the fewer the crystals. Laticiferous ducts, with their abutting end-walls, can be seen.

When assayed by the process which follows, jalap should contain not less than 8 per cent. of total resin nor more than 1.5 per cent. of ether-soluble resin.

Assay of Jalap.—Jalap, in fine powder (No. 60), 10 Gm.; ether, alcohol, chloroform, distilled water, each a sufficient quantity. Plug the tube of a funnel or small glass percolator with absorbent cotton, and put into it 10 Gm. of powdered jalap. Drench with ether, and percolate with ether, after covering the percolator, until 50 Cc. of percolate have been obtained. Evaporate off the ether from a tared beaker, and weigh the residue as ether-soluble resin. The weight so found multiplied by 10 will give the percentage of ether-soluble resin in the drug.

Percolate the powder in the percolator further with alcohol until 100 Cc. of percolate have been obtained. Measure 20 Cc. of this percolate into a separator, add 20 Cc. of chloroform, and mix. Then add 20 Cc. of distilled water, shake the liquids thoroughly for a minute, and when they have completely separated draw off the chloroform into a tared beaker. Wash the separator with 5 Cc. more of chloroform, which add to the tared beaker. Evaporate off the chloroform on a water-bath, and when perfectly dry weigh. The weight of ether-insoluble resin so found multiplied by 50 will give the percentage of ether-insoluble resin in the drug. Add to this the percentage of ether-soluble resin already determined, and the result will be the percentage of total resin contained in the drug.—U. S.

Adulterants and Substitutes.—A number of similar and related products have been used for this purpose, the principal being *Tampico Jalap* and *Male* or *Orizaba Jalap.* The former is apparently a rhizome, and is derived from *I. simulans* Hanbury. Although of irregular form, it is more inclined to be cylindrical than is jalap. Its surface is very deeply and heavily wrinkled, and the transverse markings described under jalap are wanting. This product yields rather less resin than true jalap, and this resin (tampicin) is mostly ether-soluble. It is believed to be identical with the resin of scammony. Male Jalap is less frequently seen. It is produced by *I. Orizabensis* (Pell.) Leden, and occurs mostly in irregular fragments, sometimes in entire fusiform roots, which exhibit a strong radiate structure, with projecting fibers, on transverse fracture. Its resin seems to be identical with that last mentioned.

Constituents.—Jalap contains a soft resin soluble in ether, a hard resin insoluble in ether, 2 per cent. of uncrystallizable sugar, 15 per cent. of gum, bassorin, starch, albumen, and a coloring-matter which turns red with alkaline carbonates. The Pharmacographia gave 12–18 per cent. as the average yield of resin some years ago, but now as much as 12 per cent. is seldom found. In 1888, Squibb obtained 8 per cent., and in 1889, of the finest jalap from London, New York, and Hamburg, he found only one lot that yielded over 7.5 per cent. He then had 200 pounds gathered at Jalapa, Mexico, in the old way, at the old locations, and found in it (1890) 16.9 per cent. of resin, though in appearance and fracture it was inferior to samples containing 6.5–7.5 per cent. To account for this, Flückiger suggested that the root might be washed in alcohol before shipment. The soft resin, considered a mixture by Maisch, and called *jalapin* by Mayer, is acid, has the odor and taste of jalap, and is soluble in ether and alkalies. From the latter solution it is reprecipitated by acids. It constitutes 4 to 10 per cent. of the total resin and is medicinally inert. The hard resin, *convolvulin* ($C_{31}H_{56}O_{16}$ or $C_{61}H_{108}O_{27}$, the *jalapin* of Buckner and Herberger,—*rhodeoretin*, or *jalapurgin*), is a white odorless glucoside, of acrid and nauseating taste in alcoholic solution, otherwise tasteless, soluble in alcohol and acetic acid, and insoluble in water (nearly), ether, chloroform. carbon disulphide, and turpentine. By alkalies, it is dissolved and converted into the glucoside *convolvulinic* or *convolvulic acid* ($C_{28}H_{52}O_{14}$ or $C_{62}H_{106}O_{35}$), which is amorphous, white, hygroscopic, soluble in water and alcohol, insoluble in ether, and not precipitated from alkaline solution by acids. By warming with dilute acids or by the ferment "emulsin," convolvulin is split into glucose, volatile methyl-ethyl-acetic acid ($C_5H_{10}O_2$), and convolvulic acid. This latter, by continuance of the above treatment, yields glucose and the crystalline insoluble *convolvulinolic acid* ($C_{16}H_{30}O_3$). It is unfor-

tunate that the name *jalapin* should have been applied by different authors to both resins.

In view of the great irregularity in the quality of Jalap, a convenient and accurate method for selecting the tubers is a great desideratum. Hager finds such in his way of estimating their specific gravity, which varies pretty closely with the amount of resin. Assuming that the specific gravity of good tubers is between 1.15 and 1.18, he makes a solution of common salt of a specific gravity of 1.14 to 1.142 at 15° to 17° C. (59° to 62.2° F.), and rejects all tubers which do not sink in it. Heineberg points out that in applying this method the tubers should be broken up, since cavities are often contained. He also finds that the increased specific gravity is due more to the presence of calcium oxalate than of resin. Those possessing more calcium oxalate are also richer in resin and poorer in starch, though equivalence in these ratios was not established.

Pharmaceutical Preparations.—Compound Powder of Jalap, U. S. P.; Compound Tincture of Jalap, Fluidextract of Jalap, N. F.; Resin of Jalap, U. S. P.; Tincture of Jalap, N. F.

Action and Uses.—Jalap is an active hydragogue cathartic, producing when given in overdose copious watery stools at times containing blood, severe griping, and nausea and vomiting. Combined with calomel it may be employed in congested conditions of the portal circulation, and in conjunction with potassium bitartrate it is largely used for the relief of dropsy. The jalap may be employed as a depletant, and has been given with success in cerebral congestion and plethora. It may be given in substance in the dose of from 15 to 20 grains (1–1.3 Gm.) as an active hydragogue. As a purge it may be given in 5-grain (0.30 Gm.) doses. The dose to children is from 1 to 2 grains (0.06–0.12 Gm.).

Allied Products.—The genus *Ipomœa*, L., comprises, in its broadest sense, several hundred species, mostly tropical, and well typified in our ordinary cultivated morning-glories. As thus considered, the genus includes a number of subordinate groups which are by modern botanists, and doubtless correctly, regarded as distinct genera. Many of these plants produce tuberous roots similar to those of Jalap, which, being storage-reservoirs, are rich in nutrients, so that the irritant and purgative resins which many of them contain may be properly regarded as defensive provisions, whatever other relations they may possess in the plant economy. In the *Sweet potato* or *Camote*, the tuberous root of *I. Batatas* Poir. (*Batatas edulis* Chois.), native of tropical America, and extensively cultivated in all tropical and warm-temperate regions, these resinous constituents are wanting, so that these roots constitute one of the most important of human and stock foods with a digestible nutrient content of 0.9 per cent. of albuminoids, 28 per cent. of carbohydrates, and 0.3 per cent. of fat. Besides being consumed in their natural form, enormous quantities of sweet potatoes are extracted for their starch, and alcohol or alcoholic beverages are made from them in many countries. Their starch (see Amylum) is largely employed for the adulteration of other starches, as well as of spices and other ground products. The plant exhibits many well-marked varieties, differing greatly in their economic value. Besides these, there are several other species of the genus which are similarly employed, the root of *I. graminea* R. Br. being thus used in Australia under the name *Malamak*.

The following species, containing purgative resins similar to those of Jalap and Scammony, are more or less medicinally employed.

Turpeth Root, *Vegetable turpeth* or *Indian jalap*, is the tuberous root of *Operculina Turpethum* (L.) Peter (*Convolvulus T.* L.; *Ipomœa T.* R. Br.), a species widely distributed through the East Indies, where, and to some extent in Europe and America, it has been largely used like Jalap. The root is elongated, cylindraceous, somewhat twisted, from 1.25 to 5 Cm. (½ to 2 In.) thick, and occurs cut into pieces of variable length, often with portions of the woody stem attached. It is dull-gray externally, grayish-white and somewhat spongy or porous within, the transverse section showing a thick bark containing concentric circles of small yellowish-brown resin-dots, laticiferous ducts, and cells containing calcium oxalate crystals. The inner portion of the bark exhibits also well-developed phlœm-bundles, greater in number according to the age of the bark. The meditullium is brownish-gray and softly woody, the wood occurring in 4 or 6 bundles separated by narrow medullary rays. This woody center is wanting from many pieces, having been removed through a longitudinal incision in the bark. The drug is nearly odorless and at first tasteless, afterward becoming disagreeable and somewhat acrid. The resin of Turpeth root is scarcely half so abundant as that of Jalap, which it closely resembles, only a small part of it (*convolvulin*) being ether-soluble. The remainder ($C_{34}H_{56}O_{16}$) has been called *turpethin*. The use of Turpeth root has been abandoned chiefly because of its great irregularity in strength, but its resin, which can be produced cheaply, has been recommended as a substitute for Jalap resin, than which it is considered rather more active.

Man Root, or *Man-in-the-ground*, *Wild jalap*, *W. scammony*, *W. potato*, or *W. Sweet potato Hog potato*, *Mechoacanna* (the roots of several other species are also called Mechoacanna) or *Mechamech*, is the root of *I. pandurata* (L.) Meyer (*Convolvulus p.* L.). This is a prostrate vine, bearing lance-ovate leaves with a cordate or sometimes hastate base, and grows commonly in sandy soil throughout eastern North America. The root sometimes reaches the size of a man's body, and occurs occasionally in market, cut into irregular pieces which are much more shrivelled and wrinkled than those of either Jalap or Turpeth root. It possesses a rather thin bark, containing laticiferous ducts and exuding milk when wounded in the fresh state. The dried root is brown externally and grayish-white internally. Its resin-cells are massed in a zone near the inner boundary of the bark and are scattered through the medullary rays. Man root yielded to Manz only about 1.5 per cent. of resin, a large amount of starch, some sugar and gum, and a small amount of a tannin-like substance. The glucosidal resin is completely soluble in both ether and alcohol, and is separable into two portions, the one acid, soluble in methyl alcohol and precipitated by lead salts, the other non-acid. Although this resin is quite purgative, the root itself is very feebly so.

Among the numerous other purgative roots of this genus, the following deserve mention: *I. triflora* Velasco, the *Jalap de quercetan* of Mexico; *I. Burmanni* (L.) Chois. (*I. corymbosa* Roth.; *Convolvulus c.* L.), the Mexican *Coaxihgitl*); *I. silvana* Chois. (*Convolvulus ventricosus* Mans.), the tropical American *Purga de cavallo*; *I. mestitlanica* Chois. (*I. batatoides* Benth.), the Mexican *Purgomacho*; *I. emetica* Chois. (*I. sagittata* Moc. et Ses.), the Mexican *Temécatl*; *I. maritima* R. Br. (*Convolvulus Brasiliensis* L.; *C. Pes caprœ* Roth), its root containing saponin and its milk-juice used like scammony; *I. digitata* L. (*Convolvulus paniculata* L.; *Ipomœa p.* R. Br.; *Batatas p.* Chois.; *Convolvulus roseus* H. et B.), the Indian *Bidari-kand*, *Pattana*, etc.

Mirabilis Jalapa L., a *Common four-o'clock* or *Marvel of Peru* of the flower-garden, yields a large tuberous root, known as *False Jalap* or *Metalista*, which is sometimes purgative like Jalap.

The juices of a number of species of the genus are also used as purgatives, for example, *I. Martinicensis* Chois. (*Ipomœa uniflora* R. et Sch.; *Aniseia u.* Chois.; *Convolvulus Rheedii* Walr.), of the East Indies, and *I. carnosa* R. Br., of tropical regions.

In other cases, the portion employed as a purgative is the seed. That of *I. hederacea* (L.) Jacq. (*Convolvulus h.* L.; *C. Nil* L.; *Pharbites N.* Chois.; *Ipomœa N.* Roth.; *I. triloba* Thunb.), the common *Blue morning-glory*, are known in India as *Kaladana* and in Japan as *Kongashi*. The plant is a native of tropical America, and is naturalized in most tropical countries, as well as in the United States. The seeds are similar to morning-glory seeds, and are about 2 to 3 Mm. ($\frac{1}{12}$ to $\frac{1}{8}$ In.) long. They are sometimes prepared by roasting. They contain about 8 per cent. of the resin *pharbitisin*, which appears to be identical with convolvulin, and also considerable fixed oil.

Convolvulaceæ (*the Morning-glory Family*).—The purgative properties of this beautiful and interesting family, of some 40 genera and nearly a 1000 species, are not confined to the genus *Ipomœa*. The herbage of *Convolvulus althœoides* L. (*C. Argyrœus* DC.) was the *Medion* of Galen. The root of *C. arvensis* L., native of Europe but almost everywhere introduced, is the *Hiranpadi* or *Naranji* of India. The root of *Piptostegia Gomesii* Mart. (*Convolvulus operculatus* Gom.; *Ipomœa o.* Mart.) is the *Batata de Purga* of Brazil, and yields the *Tapioca de purga*; while *P. Pisonis* Mart. is known as *Batata purgante*. Several species of *Calystegia* yield roots and herbage which are used as purgatives, and the herbage of *Cuscuta Europœa* L. (*C. major* Bauh.; *C. vulgaris* Pers.), the *Nesselseide* or *Teufelszwirn* of Europe, is thus employed. Various other species of this genus are employed as diuretics. *C. Chinensis* Lam. is the *T'u-sz'tze* of China. *C. Americana* L., of tropical America, is diuretic and poisonous and yields a yellow dyestuff.

Nearly 100 species of the family are medicinally employed in the above or other ways.

JUGLANS.—Butternut Bark.

Écorce de noyer gris, Fr.; *Graue Wallnussrinde*, G.

The dried bark of the root of *Juglans cinerea* L. (*J. cathartica* Mx.; *J. oblonga* Mill.—Fam. *Juglandaceæ*), collected in the autumn.

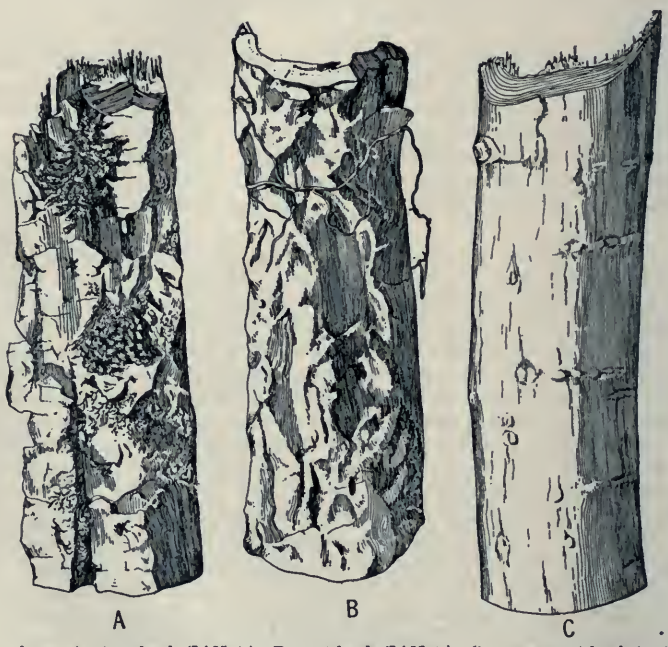
Origin.—A small, widely spreading tree, abundant in rich forest-land, especially in rocky soil, through eastern and central North America. It has a light-gray fissured bark and a soft, but durable brown wood. The foliage is light and graceful, consisting of very long pinnate leaves, which are among the first of our forest-leaves to fall in the autumn. The staminate flowers appear before the leaves, and are in thick green catkins about 10 Cm. (4 In.) long. The pistillate flowers are in little short spikes of about 5 each, and are followed by a cluster of ovoid pointed nuts, enclosed in a thin, green, viscid, bitter and acrid, tough and fibrous-pulpy husk. These nuts (*Butt-nuts*, *Oil-nuts*, *Lemon walnuts*) are very largely collected for eating purposes and are of a peculiarly

mild and delicious flavor and very oily. The bark of the root should be collected in autumn, at which time it is attached to the wood by a thin, stringy, fibrous liber which partly comes away with it and gives to the inner surface of the official bark a ragged, stringy appearance. If collected earlier in the season, it comes away with a smooth shiny surface. In the previous edition of the Pharmacopœia the inner bark was specified, and it still often comes in that form.

Description.—In quills or quilled, rarely flat, strips of variable size, the bark 3 to 10 Mm. ($\frac{1}{8}$ to $\frac{2}{5}$ In.) thick, of a deep chocolate-brown color on both surfaces, or the inner somewhat brown from adhering, ragged strips of liber, the outer surface somewhat smoothish or more or less scaly or warty; fracture short, somewhat fibrous, the transverse surface delicately checkered with white striæ; odor characteristic; taste bitter, slightly pungent, and acrid.

Pieces with a very smooth inner surface are not autumn-collected; those with a gray, fissured bark are from the stem.

FIG. 238.



Juglans: A, stem-bark (¾ Nat.); B, root-bark (¾ Nat.); C, young root-bark (× 2).

The powder is distinguished by its dark-brown color, in connection with large cells containing rosettes of calcium oxalate crystals, many of them attached to bast-fibers, the latter commonly a little narrower than the crystal-cells.

The chief adulterant of Juglans is the stem-bark, detected by the appearance noted above, and by the silver-gray particles, many of them of lichen-tissue, in the powder.

Black Walnut Bark (*J. nigra* L.) closely resembles the above. Its inner surface has more of a brown, less of a chocolate shade, and is much more coarsely striate. On transverse section it displays a brown instead of a greenish-black inner band, and this is coarsely fibrous, and there is less of the checkered appearance. Its powder shows prismatic crystals instead of crystal masses or rosettes.

Constituents.—Truman obtained by extraction with petroleum ether 4.94 per cent. of fixed oil from the trunk-bark, 5.98 per cent. from the root-bark; with strong ether, 2.31 per cent. of (mostly) crystalline resin from the stem-bark, 2.59 per cent. from the root-bark; with absolute alcohol, 6.94 per cent. of (mostly) juglandic acid from the stem-bark, 7.42 per cent. from the root-bark; of dextrin, gum, and sugar, 9.65 per cent. from the stem-bark, 11 per cent. from the root-bark. There are also a little volatile oil and a little tannin. *Juglandic acid, juglone* or *nucin* ($C_{36}H_{12}O_{10}$), is acrid, acid, sparingly soluble in water, more so in alcohol, and readily in ether, chloroform, and carbon disulphide; it crystallizes as orange-yellow needles, and acquires, with alkalies and with the alkali borates and phosphates, a handsome purple color. If the properties of the

bark depend wholly or in part on this principle, it is easily explained why continued boiling should render it less efficacious.

Pharmaceutical Preparation.—Fluidextract of Juglans, N. F.

Action and Uses.—Butternut may be employed as a mild cathartic and slight hepatic stimulant. It is claimed that its administration will produce evacuation of the bowel without causing a subsequent atonic condition of the intestinal tract. The remedy has been recommended in the treatment of acute malarial affections, and is said to be efficacious in both chronic constipation and dysentery. The official extract may be given in doses of from 5 to 15 grains (0.30–1 Gm.) as a laxative, and from 20 to 40 grains (1.3–2.6 Gm.) as a purge.

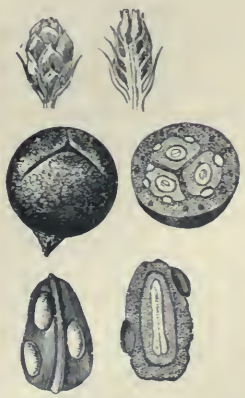
Allied Plants.—Juglans regia, L. *English walnut.*—The green pericarp (*Cortex fructus juglandis*) and the leaves (*Folia juglandis*, P. G.) have a peculiar odor and a somewhat astringent and bitter taste. The young fruit of both species is used for pickles, and when ripe the kernels yield a bland and drying fixed oil known as *nut oil;* it is greenish or pale-yellow, congeals like lard at about —18° C. (0° F.), and acquires a red color with nitric acid and a dark-brown one with a mixture of nitric and sulphuric acids. Similar oils are contained in the nuts of the numerous other nuts of this family (Hickory-nuts, Pecan-nuts, etc.), and the physical characters of their barks and leaves indicate a generally similar composition. The spring-sap of these trees is very sugary. Tanret and Villiers (1877) obtained from the leaves of the European Walnut a crystallizable non-fermentable sugar, *nucit* ($C_6H_{12}O_6.H_2O$), and Tanret (1876) reported having isolated a crystallizable alkaloid. According to Sestini, the root of the European walnut contains *glycyrrhizin*.

JUNIPERUS.—Juniper.

Fructus juniperi, P. G.; *Baccæ* (*Galbuli*) *juniperi.*—*Juniper berries*, E.; *Genièvre, Baie* (*Fruit*) *de genièvre*, Fr. Cod.; *Wachholderbeeren, Kaddigbeeren*, G.; *Enebro*, Sp. The fruit of *Juniperus communis* L. (Fam. *Pinaceæ*).

Origin.—From a large, erect shrub, prostrate in high northern regions, or rarely a small tree, distributed throughout the north-temperate zone and extending into northern Africa. It is distinguished from the common cedar by its widely spreading habit. The numerous leaves are persistent, spreading, in whorls of 3, linear and sharp-pointed; the staminate flowers are arranged in short ovoid catkins; the pistillate form a short cone consisting of about 5 imbricate whorls, each of 3 scales. Three naked ovules are situated at the base of the upper whorl, and, after fructification, these scales enlarge, coalesce, become fleshy, and ultimately enclose the seeds, forming the official berry-like galbulus, which ripens during the second year. The fruits are collected mostly in southern Europe, some in northern Africa, and are chiefly exported from Italy.

Fig. 239.



Juniperus communis L.: *a*, fertile catkin and longitudinal section; *b*, galbulus and transverse section; *c*, seed and longitudinal section, magnified.

Description.—Juniper berries are nearly globular, about 8 Mm. (⅓ In.) in diameter, dark-purplish, and covered with a bluish-gray bloom; the short stalk at the base bears 1 or 2 whorls of the small scales, and the apex is marked by 3 radiating furrows, which are surrounded by ridges, enclosing a triangular space. The 3, or by abortion 1 or 2, bony seeds are ovate in shape, triangular above, have 6 to 10 large oil-sacs on their surface, and are imbedded in a brownish pulp which likewise contains oil-cells. Juniper berries have an aromatic, somewhat balsamic odor, and a sweet, terebinthinate, bitterish, and slightly acrid taste.

Constituents.—The most important constituent of Juniper, from the medicinal standpoint, is its volatile oil (see Oleum Juniperi), the amount of which is variously reported as from 0.5 to 2.5 per cent. It apparently varies greatly in the fruits from different sections and in different samples, but probably averages considerably more than the 1 per cent. commonly stated in text-books. In the distillation of gin, the sugar (dextrose), amounting to from 15 to 30 per cent., is of great importance. There are about 10 per cent. of resin, a yellow coloring-matter, *juniperin*, apparently not active, fat, various acids, and other common plant constituents, with from 2 to 4 per cent. of ash.

Pharmaceutical Preparation.—Fluidextract of Juniper, N. F.

Action and Uses.—Juniper is somewhat stimulant and diuretic, and in the form of an infusion may be employed in the treatment of chronic inflammatory conditions of the genito-urinary tract. It may be given in the treatment of chronic nephritis, pyelitis, and in chronic inflammations of the bladder. The later stages of gonorrhœa may also be benefited by its use. It is said to decrease albuminuria, and to be a valuable adjunct to other remedies in the treatment of subacute Bright's disease. The infusion is prepared by macerating 1 ounce (30 Gm.) of the fruit with 1 pint (480 Cc.) of boiling water, all of which may be taken in 24 hours.

K.

KAMALA, *P. G.*—Kamala.

Rottlera, U. S. 1870; *Glandulæ rottleræ.*—*Kameela, Kamala*, Fr., G., Sp.

The glands and hairs obtained from the capsules of *Mallotus Philippinensis* (Lam.) Muell. Arg. (*Croton P.* Lam.; *Echinus P.* Baill.; *Rottlera tinctoria* Roxb.—Fam. *Euphorbiaceæ*).

Kamala is official in most pharmacopœias. The Russian mentions that it burns in a flame like Lycopodium, and that its aqueous extract is colored brown by ferric chloride. Several mention the chief impurities which are likely to be found in it.

Origin.—From a large evergreen shrub or small tree, common and abundant through tropical Asia and adjacent Africa, the East Indies, and Australia. The hairs and glands are removed by abrasion in baskets, through the bottoms of which they sift out. This powder consists chiefly of the red glands, but many yellowish hairs are mixed with them. The similar hairs which cover the herbage of the plant are also sometimes removed and mixed with the capsular product, reducing the quality of the drug.

Fig. 240.

Kamala (× 180).

Description.—Kamala is a fine granular, mobile powder of a brick-red or brownish-red color and somewhat resinous appearance, inodorous, and nearly tasteless. It is with difficulty mixed with water, imparts to boiling water only a yellow tinge, but a deep-red color to alkaline solutions, alcohol, ether, chloroform, and benzene. When thrown into a flame it burns similarly to, but less rapidly than, Lycopodium, and when heated in a crucible it leaves a small amount of ash, which weighs from pure kamala 1.37 per cent. (Pharmacographia). Examined under the microscope, the glands are seen to be depressed-globular, and to consist of a thin, transparent membrane enclosing a yellowish mass, in which are imbedded many club-shaped vesicles radiating from a common center, and containing a red substance; this structure becomes more apparent after treating the glands with potassa and pressing them between glass. The glands are always mixed with colorless stellately arranged simple hairs, but fragments of leaves and stems should not be present. Very slight amounts of mineral impurities are liable to exist, from adherence to the rough surface of the capsules, but the amount is scarcely sufficient for detection by the microscope.

Adulteration is practised extensively. The addition of the plant-hairs noted above imparts a yellowish or pale color. The chief addition consists of red sand or other earthy matters, and has sometimes been so great as to cause an ash yield of 40 to 50 per cent. Ferric oxide has been similarly used. Other adulterants, which do not thus affect the ash percentage, are dyed starch, broken carthamus, and the related products mentioned at the close of this article. All these are readily detected by microscopical methods.

Constituents.—Kamala contains a small amount of sugar, starch, tannin, citric and oxalic acids, a trace of volatile oil, and about 80 per cent. of a dark brownish-red resinous matter, composed of rottlerin, isorottlerin, wax, a resin freely soluble and one less soluble in alcohol, and a trace of coloring-matter. The ash in the best quality amounts to from 1.5 to 3 per cent. (the P. G. allows 6 per cent.), and contains considerable manganese; if the ash is reddish, ferric oxide is present. The two resins have the formulæ $C_{15}H_8O_4$ and $C_8H_{12}O_5$, and both are brittle, reddish-yellow, and soluble in alkalies. *Rottlerin* (or "kamalin,"—$C_{22}H_{20}O_6$) crystallizes in yellow silky needles or plates, is soluble in ether, alkalies, and boiling alcohol, sparingly soluble in cold alcohol, insoluble in water, and not permanent in air. Fused with potassa, it yields para-oxybenzoic acid. It may be the *mallotoxin* ($C_{18}H_{16}O_5$ or $C_{11}H_{10}O_3$) obtained by Perkin and by Jawein.

Action and Uses.—Kamala is a drastic purgative producing considerable griping. It frequently causes nausea, but seldom vomiting. It was first employed as a tænifuge, and was said to be especially useful in removing *Tænia solium*. It has since been

given also for the removal of round worms. The dose is from 1 to 3 drachms (4–12 Gm.), suspended in water or syrup, to which may be added some hyoscyamus to prevent griping. A tincture made with 6 ounces (180 Gm.) of the drug and 1 pint (480 Cc.) of alcohol may be given in doses of from 1 to 4 fluidrachms (4–16 Cc.). This dose may be repeated in 8 hours if necessary, and followed a few hours later by castor oil.

Allied Substances.—WARS, WARRAS, or WURRUS.—This name, which is the Arabian for saffron, has occasionally been given to kamala, but in eastern Africa is given to a distinct drug of unknown origin, but used for dyeing, and medicinally like kamala. It forms a rather coarse powder of a deep-purple color and slight odor, becomes black at the temperature of a water-bath, yields from 6 to 12 per cent. of ash, and under the microscope is seen to consist of cylindrical or subconical glands enclosing oblong vesicles arranged in 3 or 4 tiers; the glands are mixed with rather long, simple hairs.

KAOLINUM, *U. S., Br.*—Kaolin.

Terra porcellanea.—Porcelain clay, Fullers' earth, E.; *Terre à porcelaine,* Fr.; *Porcellanerde, Porcellanthon,* G.

A native aluminum silicate, consisting largely of the pure silicate ($H_2Al_2Si_2O_8 + H_2O = 257.12$), powdered and freed from gritty particles by elutriation.—U. S. It is found in large deposits in the earth, and is a product of the weathering action of carbon dioxide and water on feldspar, which is a potassium aluminum silicate, $KAlSi_3O_8$. In this action potassium silicate is formed, which is carried off by rain water and, being absorbed by the soil, serves as food for plants, while insoluble kaolin remains. It is used to a large extent in the industries, for clarifying beer, wine, honey, sugar solutions, oils, such as lard and cotton-seed oil and mineral oils. For pharmaceutical purposes, it should be extracted with 5 per cent. hydrochloric acid to remove lime, and levigated to remove sand, etc.

Properties and Tests.—When purified, kaolin is a soft white powder or lumps, having an earthy taste, odorless, insoluble in water and in cold dilute acids and alkalies. Moistened with water, it becomes darker in color and acquires a marked odor of clay. It is used as an absorbent dusting-powder, and as an excipient in pills in the case of substances like silver nitrate, potassium permanganate, etc., which act on organic excipients. If 1 Gm. of kaolin be mixed with 10 Cc. of water and 5 Cc. of sulphuric acid in a porcelain dish, no effervescence should occur, and if the mixture be evaporated and further heated until dense white fumes of sulphuric anhydride appear, then after cooling and adding 20 Cc. of water, boiling for a few minutes and filtering, there should remain on the filter a gray residue of silica. If to one-half of the filtrate ammonia water be added, a gelatinous precipitate of aluminum hydroxide, insoluble in excess, should be obtained. If to the remaining half of the filtrate sodium hydroxide solution be added, it should yield a gelatinous precipitate which is almost or completely soluble in an excess of the alkali. If 2 Gm. of kaolin be rubbed with 10 Cc. of water, the mixture should not acquire more than a slight reddish tint with 0.5 Gm. of sodium salicylate (absence of more than a trace of iron). Not less than 85 per cent. of non-volatile residue should be left when kaolin is ignited at a red heat.—U. S.

Pharmaceutical Preparation.—CATAPLASM OF KAOLIN, U. S. P.

Action and Uses.—Kaolin is never employed in internal medicine, but is occasionally applied locally as a dusting-powder in the treatment of eczema.

KINO, *U. S., Br.*—Kino.

Gummi (or *Resina*) *kino, Indian kino, Malabar kino.—Kino de l'Inde,* Fr. Cod.; *Kino,* G.; *Goma quino,* Sp.; *Tanoma Kino,* Port.

The inspissated juice of *Pterocarpus Marsupium* Roxb. (*P. bilobus* Roxb.—Fam. *Leguminosæ*).

Origin and Collection.—Kino is collected from a large deciduous forest-tree of India and Ceylon, most abundant and most utilized in the north Malabar district of Madras. It appears to present quite a number of distinct forms, which Prain has

arranged in two varieties. The product had become, during the close of the nineteenth century, scarce and costly, but the recent opening of very extensive new districts insures "an unlimited supply at a price that will preclude all competition of other articles of a similar nature" (Watt). The right to tap the trees is let by the government to the highest bidder. The juice flows freely at all seasons, but is chiefly collected in the dry season (February and March), when the tree is in bloom, since the juice is at other times inferior, and artificial drying of the Kino would be required. It runs better at night, and small or middle-sized trees yield better than large ones. If fully tapped, a tree must rest a year before it will again yield. Bleeding may be made so profuse as to kill the tree. A tree ordinarily yields about 1½ pounds of juice, which produces half as much Kino. Incisions are made down to the cambium, and the juice is caught in clay cups, bamboo-joints, or other convenient receptacles, and is boiled soon after collection. The impurities are skimmed off during the boiling, and after reaching the consistency of a thick extract the mass is poured into pans, in thin layers, to dry until it will crumble readily. If kept in the shade, a half-inch layer will dry in 7 or 8 days.

Description.—East India or Malabar Kino is met with in small, angular, dark brownish-red, glistening, and brittle pieces, which in thin layers are transparent and of a ruby-red color, and tinge the saliva deep-red; it softens between the teeth, is inodorous, and has a very astringent and sweetish taste. It is partly soluble in cold water, leaving a flocculent residue, and is entirely soluble in alcohol and nearly insoluble in ether. The solutions have an acid reaction; the aqueous solution is precipitated green-black by ferric salts, gray-purplish by lead acetate, light-brown by tartar emetic, and reddish by mercuric chloride. The solution in diluted alcohol is apt to gelatinize.

The Russian pharmacopœia specifies that Kino has an acid reaction, and it rejects those Kinos which, containing gum, swell in water and alcohol. Several specify that the filtrate, after shaking Kino with water, is turned dark-green by ferric chloride. Dragon's blood, used as an adulterant, is insoluble in water.

Constituents.—Considerable erroneous or doubtful information has been supplied concerning the composition of Kino, as a result of the use, for examination, of products from different botanical sources, these being very numerous. It has been believed to consist chiefly (about 40 to 80 per cent.) of *kinotannic acid*, giving a blackish-green reaction with ferric chloride, and very similar to catechutannin. Kinotannic acid acts like the last-named, from Catechu and Gambir, when fused with potassa, and it yields phlobaphene. It has not yet been obtained in a pure condition, being accompanied by red coloring-matter, and, according to Hennig (1853), by a pectin compound from which it cannot easily be freed. The aqueous solution of the acid gives with pure ferrous salts, when carefully neutralized, a violet color, and with ferric salts a blackish-green one. Mineral acids and many metallic salts produce precipitates; hot nitric acid converts it into oxalic acid. In solution, it is darkened by alkalies. On exposure to air the aqueous solution yields a red precipitate, slowly at the ordinary, more rapidly at the boiling, temperature; this is *kino-red*, an amorphous, tasteless mass, the alcoholic solution of which has a slight acid reaction. Kino-red ($C_{28}H_{22}O_{11}$) is also produced by heating kinoin to 130° C. (266° F.). This compound was obtained by Etti (1879) by boiling supposed kino with diluted hydrochloric acid and agitating the clear liquid with ether; it forms white crystals, the solution of which in water becomes red with ferric chloride. The presence in genuine Kino of the above-described substances has been recently denied by White (*Phar. Jour.*, May, 1903, p. 676), who, following Etti's process with Kino the identity of which had been fully proved, extracted only a fraction of a per cent. of protocatechuic acid. He concluded that Etti's supposed Kino was some one of the numerous similar substances which have gone under that title. Kino contains 13 to 15 per cent. of moisture, and about 1 to 2.5 per cent. of ash.

Pharmaceutical Preparations.—Compound Powder of Kino, Compound Tincture of Kino, N. F.; Tincture of Kino, U. S. P.

Action and Uses.—At present kino is chiefly employed in the treatment of serous diarrhœa, in which condition it is frequently combined with opium or used in conjunction with chalk mixture. It has also been recommended in chronic dysentery and in pyrosis. Its administration in diabetes and in intestinal hemorrhage has been regarded as useful, but the other vegetable astringents are probably equally efficacious.

An infusion made by macerating 2 drachms (8 Gm.) of kino in 8 fluidounces (240 Cc.) of boiling water, and straining, may be beneficially employed as a gargle in sore throat and relaxation of the uvula; as an injection in the treatment of leucorrhœa and the later stages of gonorrhœa; and as an irrigation in epistaxis, intestinal, uterine, and other passive hemorrhages. The powder has been locally employed for the control of hemorrhage and in the treatment of indolent ulcers.

Kino may be prescribed in powder in the dose of from 10 to 20 grains (0.60–1.3 Gm.); in infusion (1 ounce (30 Gm.) to 1 pint (480 Cc.) in the dose of from 1 fluidrachm to 1 fluidounce (4–30 Cc.); and in tincture in the dose of 1 fluidrachm (4 Cc.).

Other Varieties of Kino, and Allied Substances.—The number of substances which have been offered as Kino, or which resemble it in appearance and properties, is very great, and only the more important of them can here be mentioned.

The genus *Pterocarpus*, L., comprises some 20 species, of the Old and New World tropics, and several of them yield Kinos. *African* or *Gambia Kino* is the product of *P. erinaceus* Poir. (*P. echinatus* Pers.?), and has never been an article of commerce to any considerable extent. Its yield of tannin is about 50 per cent. or more. *P. Draco* L., of the West Indies, yields a Kino which is one of the substances which have been known as "West Indian," and has been somewhat confused with Dragon's blood. *P. dalbergioides* Roxb., of India, yields an inferior Kino.

Schaer reports upon an African Kino from *P. Bussei* Harms., which closely resembles Malabar Kino externally, though the fragments are more regularly and sharply angular and there are many adhering particles of bark. Cold water dissolves it slowly and incompletely, and pyrocatechin and kinoin could not be detected. The same author obtained from the same region two similar but inferior Kinos, respectively collected from *Derris Stuhlmannii* and *Berlinia Eminii*.

Palas or Bengal Kino, from *Butea frondosa* Roxb. and several other species of *Butea*, of the same family, is the *Dhak* of India, or *Tsze-kwang* or *Ch'ih-Kiau* of the Chinese. It occurs in dark ruby-colored tears and fragments, of which only about one-half or less is soluble in hot alcohol, the remainder being mucilaginous matter. According to Eissfeldt, it does not contain pyrocatechin, but yields this compound on dry distillation. When incinerated, Butea gum leaves about 1.8 per cent. of ash. It yields only 15 to 35 per cent. of tannin. *Ougeinia dalbergioides* Benth. and *Sesban grandiflora* Poir., of India, also yield Kinos.

Eucalyptus Kino or Gum, *Australian* or *Botany Bay Kino* (*Eucalypti Gummi* of the B. P.), is the most important substitute. It is collected from a number of species of *Eucalyptus*, chiefly from *E. rostrata* Schlecht. Sixteen different species were recorded by von Müller as yielding it, but not all of these products have been examined, and it is only practicable, for the present, to identify it by its properties, not by its sources. It is collected mostly from artificial incisions, the yield being about the same per tree as of ordinary Kino, and is usually dried by artificial heat. Considerable is also collected in a dry state from cavities in the trunk. It occurs in small pieces, usually larger and less angular than those of Kino, which they closely resemble in color and transparency. It is rather dusty, is not so brittle as Kino, adheres to the teeth, tinges the saliva red, and is very astringent. It dissolves almost completely in alcohol, but only 80–90 per cent. of it in cold water, the solution being neutral. It contains about 45 to 50 per cent. of kinotannic acid, with kino-red, catechin, etc. Much, if not all, of the gum of commerce loses its solubility in water on being kept for a long time. Eucalyptus Kino may be employed for the same purposes and in the same doses as *Kino*.

Liquid or Angophora Kino is derived from a tree quite closely related to *Eucalyptus*, the *Angophora intermedia* DC., the so-called *Victorian apple-tree* of Australia. The substance exudes very freely from incisions, from 2 to 10 gallons being obtained from a tree. This juice is quite watery, occasionally quite thick, and varies from colorless to reddish-brown. It is used by fishermen, under the name "Apple-tree juice," for coloring their nets. According to its thickness it yields more tannin, the amount varying from less than 1 to 3 or 4 per cent.

Myristica Kino is obtained in India from *M. gibbosa* Hook. f., *M. Kingii* Hook. f., and some other species. It quite closely resembles the Malabar, and contains about 30 per cent. of kinotannic acid.

Jamaica, West Indian, or Caracas Kino, from *Coccoloba uvifera* L., or *Sea-side grape* (Fam. *Polygonaceæ*), is obtained by boiling the wood and bark and evaporating the decoction. It resembles Malabar Kino in appearance, but is of a brown tint, less glossy, and has a bitterish rather than a sweetish taste; it is soluble in both alcohol and water to the extent of about 90 or 93 per cent. The plant named is a large shrub or tree of the West Indies and southern Florida, and has a heavy, hard, and durable violet-brown wood.

In this connection, reference may be made to the very similar substance, *Quebracho extract*, obtained by boiling the wood of the red Quebracho, derived from two or more species of the genus *Schinopsis*, of Argentina, Paraguay, etc. *S. Balansæ* Eng., *S. Lorentzii* (Griseb.) Eng., and *S. Morongii* (Britton) Rusby, are named as the sources. This extract has an appearance intermediate between Logwood extract and Kino. It is not used in medicine, but is employed upon an enormous scale in the tanning of leather. It contains about 70 per cent. of tannin.

The *Resina d'angelin pedra* is a kino-like extract obtained in Brazil from *Ferreira spectabilis* Allem., also of the *Leguminosæ*. It contains the alkaloid *angeline* or *ratanhine* ($C_{10}H_{13}NO_3$).

Hooper describes an East Indian Kino from *Macaranga Roxburghii* Wright (Fam. *Euphorbiaceæ*), and from other species of *Macaranga*. It is of peculiar consistency, and is used for taking impressions, like sulphur, but is free from the brittleness of the latter substance. From a half to three-fourths consists of insoluble gum, and only about 10 to 15 per cent. of tannin is contained.

Kino-like extracts are also obtained from *Milletia megasperma* Benth., of Australia, and *Machærium fertile* Griseb., and *Iodina rhombifolia*.

KRAMERIA, *U. S.*—Rhatany.

Krameriæ radix, Br.; *Radix ratanhiæ*, P. G.; *Radix ratanhæ*, *Rhatany root*, E.; *Ratanhiawurzel*, G.: *Ratanhia*, Fr.; *Ratania*, It., Port., Sp.; *Crameria*, Sp.

The dried root of *Krameria triandra* Ruiz et Pav. (*K. tomentosa* St. Hil., *Peruvian* or *Payta K.*), of *K. Ixina* L. (*Ixina Granatensis* Tr. et Pl., *Savanilla K.*), or *K. argentea* Mart. (*Para*, *Brazilian*, or so-called *Savanilla K.*).—(Fam. *Krameriaceæ*, or *Leguminosæ*, *fide* Engler et Prantl.)

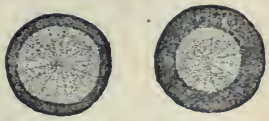
Krameria is official in all pharmacopœias, which differ greatly in the named sources. Those differences, as shown by their accompanying descriptions, are chiefly due to mistakes of identity as to the different varieties (see *Origin*), that adopted in the definition of one, being rejected by that of another, though comprised in its description. Several specify the root-branches, thus excluding the woody crown, a wise precaution. Several specify the exclusion of that deprived of its bark, one excludes the wood (practically impossible except as to the powder), and the Italian requires that it contain 20 per cent. of tannin. The Swiss mentions that the alcoholic tincture gives a red precipitate with alcoholic solution of plumbic acetate and the filtrate retains the red color. Several mention that the aqueous maceration is colored green by ferric chloride and yields a brown precipitate.

Origin.—*K. triandra* is a low, intricately branched, very woody shrub, inhabiting arid localities in the high mountains of Peru, Bolivia, etc. Its short branchlets are sharp and spine-like, its leaves silvery-hairy, its irregularly cross-shaped flowers scarlet or crimson, which endears it to the religious inhabitants. We have ourselves collected

FIG. 241.

Peruvian krameria: small root (Nat.).

FIG. 242.



Rhatany root: *a*, Payta root; *b*, Savanilla root.

this shrub with roots attached, and identified the latter with the commercial article so described below. *K. Ixina* is regarded as a widespread species from Mexico, through northern South America, and into the West Indies, and presenting a number of varieties. When better known, the latter are likely to be regarded as distinct species. The typical article comes from the United States of Colombia and Venezuela. For many years it has been nearly or quite absent from the market, but it is now coming forward sparingly. In the meantime the root of *K. argentea* (*Brazilian*, *Para*, or *Ceara Rhatany*, *Ratani de terra* or *R. des Antilles*), of northern Brazil, has been sold for it. When Savanilla rhatany, the better variety, is called for, the Peruvian is very frequently supplied, and our best dealers are apparently mistaken or uncertain as to their

identity. The name "Ratania da terra" for the Brazilian, means merely "Native Krameria."

Description.—*Peruvian Krameria.*—Root-branches usually occurring with several or many attached to a short, hard, and woody tap-root, which is 1.5 to 4 Cm. (½ to 1½ In.) thick, roughly fissured, and supports a knotty, several- to many-headed crown; of indefinite length, rarely exceeding 50 Cm. (20 In.) and usually less than 1 Cm. (⅖ In.) thick, cylindrical, flexuous or wavy, very flexible; externally light red-brown, more or less marked with dark, scaly patches, especially upward, otherwise smoothish, devoid of transverse fissures; fracture tough and splintery, the pinkish-brown bark occupying less than one-third of the radius, the wood yellowish or pinkish-white, finely radiate; inodorous and of a very astringent taste.

Brazilian Krameria.—Branches usually occurring detached from the tap-root and crown, less flexuous than those last described, externally of a deep purple-brown or chocolate-brown and with numerous transverse cracks or fissures; fracture less tough than that of the last, the bark and wood both darker, the former occupying two-fifths, or even more, of the radius, the taste more astringent than that of the last.

Savanilla Krameria is very similar to the Brazilian, but there is rather more of the red-purple to its color, it is less fissured and its bark not quite so thick, proportionately.

The Russian Pharmacopœia directs that only the bark shall be taken for the powder, but the whole root for the liquid preparations. In a good sample the bark weighs at least 50 per cent. of the whole.

Constituents.—The active constituent is *ratanhia-tannic* or *Krameria-tannic acid*, which is precipitated dark-green with ferric salts and flesh-colored by gelatin, but not precipitated by tartar emetic. By fusion with caustic potash it yields protocatechuic acid and phloroglucin, and with dilute acids forms sugar and *ratanhia-red* ($C_{26}H_{22}O_{11}$), a coloring principle similar to that yielded by the tannins of horse-chestnut and tormentil; on dry distillation, pyrocatechin distils over. On exposure to air, the tannin is slowly changed to an insoluble, non-astringent phlobaphene or anhydride, some of which exists in the plant. The other constituents are starch, uncrystallizable sugar, a trace of gum, wax, and a peculiar acid, *krameric acid.* Of the tannin, Dunwody (1890) obtained 8.4 per cent. from *K. triandra,* and 7.2 per cent. from *K. argentea.* Wittstein extracted 17.8 per cent. from Payta rhatany, and 3.2 per cent. from the Savanilla variety. An amido-acid principle, *ratanhine* or *methyl-tyrosin,* which forms salts with mineral acids or strong bases, has been found in extracts of rhatany, in other plants of Brazil, and to the extent of 86 per cent. in *resina d'angelim pedra* (see under KINO), but its presence in krameria is probably due to adulteration with these latter.

Pharmaceutical Preparations.—EXTRACT OF KRAMERIA, FLUIDEXTRACT OF KRAMERIA, TINCTURE OF KRAMERIA, U. S. P.

Action and Uses.—Krameria is tonic and astringent, and when given to excess produces gastric distress and constipation. It may be employed in serous diarrhœa, and is recommended in chronic diarrhœa, passive hemorrhages (especially from the uterus), and in certain forms of leucorrhœa. Locally applied, a watery solution is said to be advantageous in the treatment of fissured nipples, and rectal injections, made by dissolving from 40 to 90 grains (2.6–6 Gm.) in 5 ounces (150 Cc.) of water have met with favor in the treatment of dysentery and in fissure of the anus.

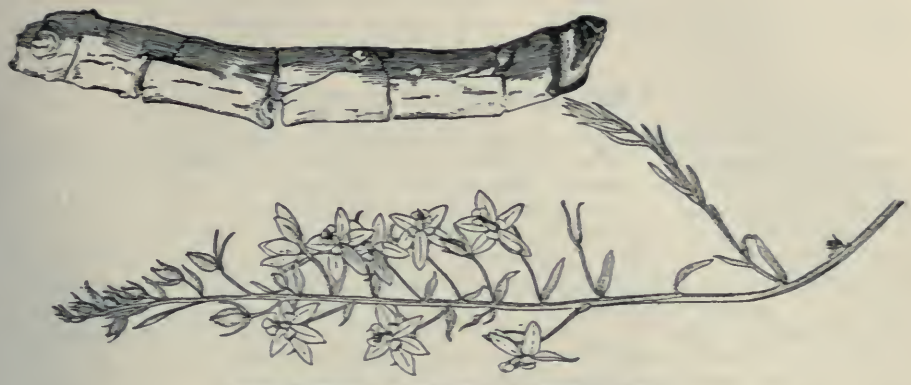
Krameria is administered in the dose of from 10 to 30 grains (0.60–2 Gm.) in powder. The extract, fluidextract, and tincture are given in doses of from 5 to 10 grains (0.30–0.60 Gm.), 5 to 30 minims (0.30–2 Cc.), and ½ to 2 fluidrachms (2–8 Cc.), respectively.

An infusion (krameria 1 ounce (30 Gm.) and boiling water 1 pint (480 Cc.)) may be given in the dose of from 1 to 2 fluidounces (30–60 Cc.).

Other Species, Substitutes, and Allied Drugs.—*Krameria cistoides* Hook. et Arn., a native of Chile, produces a root which, according to Schroff (1869), closely resembles Payta rhatany; the wood of the thick main root is pale-reddish in the outer layer and brown-red in the center.

Texas rhatany has been described by Berg; it is derived from *K. lanceolata* Torr. (*K. secundiflora* DC.), and consists of a roundish root-stock about 2 In. (5 Cm.) thick, from which a number of long roots emanate which have a blackish-brown, internally reddish, bark of the same thickness as the wood. This bark is much more spongy than that of the others and occurs much fissured and broken.

FIG. 243.



Texas krameria: *a*, root (Nat.); *b*, branch (½ Nat.).

The genus *Krameria* is regarded as containing 13 species, all American, and they are probably all more or less uniform as to the constituents and properties of their roots.

Ceanothus is the root, or the bark of the root, of *C. Americanus* L. (Fam. *Rhamnaceæ*), the *Red root*, *New Jersey* or *Walpole tea*, *Sprangles*, *Seckelblume* or *Ceanothe*, a low, densely branching shrub of eastern and central North America. The plant is 2 or 3 feet high, and about as broad, with very many erect, slender branches, alternate oval-ovate, 3-nerved, serrate leaves, downy underneath, numerous short and broad axillary panicles of very small white flowers, followed by 3-lobed pods, somewhat similar to those of the tea-plant. The root is very woody and tough, having a large knotty crown, a stout tapering primary root about an inch thick and 1 to 1½ feet long, with few or many strong branches, mostly from the upper portion. The bark is of a deep brownish-red, more or less streaked with gray or whitish lines. It is a little fissured. The wood has a tough splintery fracture and cuts with a somewhat waxy surface. It is red internally. There is little odor, but a strongly astringent taste. The useful properties of the drug appear due entirely to its tannin, of which there is about 9 per cent. It exists in both the bark and the wood, but chiefly in the bark. There is also 0.2 per cent. or more of an amorphous alkaloidal substance. It has been named Ceanothine, but Gordin finds good reason to believe that it is a mixture. There are also a peculiar coloring-matter, *ceanothus-red*, a little resin, fat, starch, etc. Its uses are purely as an astringent. It is said to have been used as an adulterant of Krameria, and it certainly appears well qualified to subserve such a purpose. The leaves are said to have been used as a substitute for tea during the Revolutionary period, and to make a very good substitute, as far as flavor is concerned.

FIG. 244.

Ceanothus: *a*, branch (¾ Nat.); *b*, fruit (× 6).

The genus *Ceanothus*, L., contains about 40 species, mostly of western North America, where they grow very abundantly. They appear generally to possess the same astringent properties as the above. An alkaloid was found in *C. reclinatus* L'Herit., but it appears different from that of *C. Americanus*.

L.

LABIATÆ.—The Mint Family.

This great family, of more than 150 genera and about 3000 species, is in all respects most uniform and homogeneous. Most of its members are readily distinguishable by the following simple characteristics: In temperate climates herbs, frequently becoming shrubby, or occasionally even small trees, in warm countries; stems or branches square; leaves opposite, without stipules, aromatic; calyx tubular and commonly 2-lipped; corolla tubular and almost always 2-lipped, bearing within 2 stamens, or 4 stamens in 2 pairs; fruit separating into 4 small seed-like nutlets. These plants are distributed over almost the entire globe, chiefly in temperate and subtropical regions.

Constituents.—Alkaloids are wanting, and glucosides are rarely if ever present. The important constituents are volatile oils, amaroids, and tannin, occurring alone or in variable proportion, thus imparting aromatic, bitter, or astringent properties, the last-mentioned rarely (when the tannin amounts to 5 per cent. or more) in important degree. Aromatic properties are pre-eminent, both in degree and frequency, so that our principal study of the properties of the drugs will be found under the title OLEA VOLATILES. For this reason also, the properties of these drugs are highly subject to deterioration with age, resulting from evaporation. Special properties, such as those of menthol or rosemary, occasionally occur, but published statements concerning specific properties in newly proposed drugs of this family should be accepted with great caution. A few are slightly irritant and poisonous. The dose of the herbs of this family is almost always 30 to 60 grains. Tinctures or fluid extracts are usually the best form of preparation. Infusions work fairly well, especially those of astringents, while decoctions are usually inefficient. As aromatics, these drugs act especially as carminatives, and the aromas and flavors are usually pleasant, thus well adapting them for use in perfuming and flavoring.

We give below an artificial structural key to the genera of the more commonly used drugs of the family. The names of those to which separate articles are accorded are printed in capitals. Brief accounts of the others will be found following the key. It is believed that such a key will be found especially useful in this case, since the drugs, with few exceptions, are employed in the form of the flowering herbs:

ARTIFICIAL KEY TO THE PRINCIPAL DRUG-YIELDING GENERA OF THE LABIATÆ.

	Ovary 4-parted. (1)
	Ovary lobed, at most not more than half way. (28)
1	Stamens 4. (2)
	Stamens 2. (8)
2	Stamens declined. (3)
	Stamens erect, divergent or ascending. (4)
3	Stamens exserted. (12)
	Stamens included in the corolla-tube. (13)
4	Calyx-nerves 5 or 10; upper lip of corolla concave. (11)
	Calyx-nerves 13 or fewer; corolla-lobes plane. (5)
	Calyx-nerves 15. (10)
5	Anthers 1-celled. (14)
	Anthers 2-celled. (6)
6	Calyx 5-nerved. (15)
	Calyx 10-nerved. (16)
	Calyx 13-nerved. (7)
7	Calyx equal or slightly 2-lipped. (17)
	Calyx distinctly 2-lipped. (18)
8	Calyx 2-lipped. (19)
	Calyx not 2-lipped. (9)
9	Calyx not hairy in the throat. (20)
	Calyx-throat hairy, at least in fruit. (21)
10	Calyx either open-campanulate and equal, or distinctly 2-lipped. (22)
	Calyx tubular, the mouth merely more or less oblique. (23)

11
- Calyx dorsally flattened, 2-lipped. (24)
- Calyx 10-toothed ; stamens included in corolla-tube. (25)
- Calyx 5- to 10-toothed, the teeth dilated at base, or coherent into an orbicular spreading limb. (26)
- Calyx 5-toothed ; stamens more or less exserted. (27)

12
- Corolla-tube short, the anterior or lower lobe flat or only slightly concave . *Ocimum.*
- Corolla-tube long exserted, the anterior or lower lobe flat or slightly concave . *Orthosiphon.*
- Anterior or lower corolla-lobe saccate, with a narrow stem-like base. *Mesosphærum.* (Hyptis.)

13 . . . . . LAVANDULA.

14 . . . . . *Pogostemon.*

15 . . . . . *Satureia.*

16
- Calyx in flower nearly equally 5-toothed, in fruit greatly enlarged, declined and 2-lipped ; corolla 5-lobed, the lower lobe much the largest and toothed or fimbriate . . . . . *Collinsonia.*
- Calyx as in *Collinsonia ;* corolla 5-lobed, the lower lobe but little larger, entire . . . . . *Perilla.*
- Calyx in flower 2-lipped, the upper lip shortly 3-toothed, the lower slenderly 2-toothed ; corolla 2-lipped . . . . . THYMUS.
- Calyx nearly equally 5-toothed ; corolla 4-lobed . . . . . MENTHA.

17
- Stamens straight or divergent . . . . . *Koellia.* (Pycnanthemum.)
- Stamens ascending at the base, conniving at the summits . . . . . *Micromeria.*
- Stamens ascending at the base, diverging at the summits . . . . . *Origanum.*

18
- Flowers in dense terminal bracted capitate cymes . . . . . *Majorana.*
- Flowers in dense axillary whorls . . . . . *Calamintha.*
- Flowers few in loose axillary whorls . . . . . MELISSA.

19
- Calyx distinctly 2-lipped ; corolla strongly double-curved ; anther-cells widely separated, the lower partly aborted . . . . . SALVIA.
- Calyx shortly toothed, slightly oblique, not distinctly 2-lipped ; lower anther-cell wanting, only a short portion of its connective remaining . *Rosmarinus.*
- Corolla-tube straight ; filaments of the two sterile stamens equalling the others ; anther-cells 2, diverging . . . . . HEDEOMA.

20 . . . . . *Lycopus.*

21
- Calyx 10- to 13-nerved ; anthers 2-celled, the cells distinct and parallel . *Cunila.*
- Calyx 15-nerved ; anthers affixed at the middle, the cells diverging and at length confluently 1-celled . . . . . *Monarda.*

22
- Calyx open-campanulate, equal . . . . . *Hyssopus.*
- Calyx tubular, 2-lipped, the posterior or upper lip much larger than the others . . . . . *Dracocephalum.*

23
- Stamens long-exserted, erect or divergent . . . . . *Lophanthus.*
- Stamens ascending under the upper lip ; anther-cells diverging . . . . *Nepeta.*
- Stamens ascending, the anther-cells parallel . . . . . *Cedronella.*

24
- Upper lip of calyx enlarging in fruit to form a large helmet-shaped erect appendage . . . . . SCUTELLARIA.
- Upper lip of calyx 3-toothed, the lower 2-cleft . . . . . *Prunella.*

25 . . . . . MARRUBIUM.

26 . . . . . *Ballota.*

27
- Nutlets rounded at summit ; corolla-tube cylindraceous ; anther-cells divergent . . . . . *Stachys.*
- Nutlets rounded at summit ; corolla-tube with dilated throat ; anther-cells placed back to back, transversely valved *Galeopsis.*
- Nutlets truncate ; acutely angled ; corolla-tube included ; anther-cells parallel . . . . . *Leonurus.*
- Nutlets truncate, acutely angled ; corolla-tube exserted ; anther-cells divaricate . . . . . *Lamium.*

28
- Upper lip of corolla wanting, the lateral lobes of lower lip almost so . *Teucrium.*
- Upper lip of corolla small, 2-cleft, the lower 3-lobed . . . . . *Ajuga.*

OCIMUM, L., is a genus of about 60 species, 20 or more of which are medicinally employed. *O. Basilicum* L. (*O. majus* Hort. ; *O. medium* Mill. ; *O. minimum* L.) is the *Common*

or *Sweet Basil* (*Basilienkraut*, G.; *Basilic*, Fr.; *Albahaca*, Sp.), a native of southern Asia and adjacent Africa, and very largely cultivated. The stem is branching and more or less pilose; the long petiolate leaves are oblong-ovate, somewhat toothed, smooth, and beneath glandular-punctate; the flowers are in somewhat interrupted spikes, the calyx short and ciliate, and the corolla white or reddish, with a short tube, a broad 4-lobed upper lip, and a descending spatulate lower lip. The herb has a strong and agreeable aromatic odor and a balsamic and cooling taste; it contains volatile oil and a little tannin. *O. gratissimum* L., of the same region, and several other species are quite similar, but inferior.

ORTHOSIPHON STAMINEUS Benth. is the *Java tea*, used to some extent as a substitute for tea in the East Indies.

MESOSPHÆRUM (HYPTIS) is a large genus in tropical America, some Andean species becoming large shrubs or even small trees. They are strongly and delightfully aromatic, and find many uses among the natives.

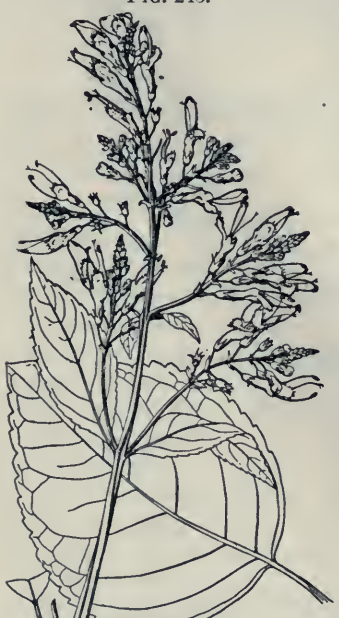
POGOSTEMON HEYNEANUS Benth. (*P. Patchouly* Pelletier; *P. suavis* Tenore), the *Patchouli balm*, native and cultivated in the East Indies, yields oil of patchouli. Since the oil only occurs in commerce to any extent, the herb itself is here of little interest. *Microtœna cymosa* Prain, of Cochin China, is used like patchouli.

SATUREJA HORTENSIS L., or *Summer savory* (*Saturei*, *Pfefferkraut*, *Wurstkraut*, *Bohnenkraut*, G.; *Sarriette*, Fr.), is a native of Europe, and is everywhere cultivated as a medicinal and culinary herb. The stem is much-branched, roughish-pubescent; the leaves are linear-lanceolate or oblong-linear, entire, acute, and tapering into a very short petiole; the cymules are about 3-flowered, with the corolla pale-purplish, and with 4 diverging rather included stamens.

SATUREJA MONTANA L. (*Micromeria m.* Reichenbach) is the *Winter savory*, and is less used. It is suffruticose, retrorsely hairy, and has hairy whitish or reddish flowers in small axillary clusters, and linear-lanceolate, mucronate leaves, pellucid-punctate and rough on the margin. Haller (1882) obtained from it 0.83 per cent. of volatile oil having an orange-yellow color, an odor resembling that of origanum, and the density 0.7394 at 17° C. (62.6° F.); it is lævogyre, and contains 2 hydrocarbons and 2 phenols, one of the latter being identical with *carvacrol*.

COLLINSONIA CANADENSIS L., *Stoneroot*, *Richweed*, *Horse-balm* or *Ox-balm*, *Citronella*, *Knob-root* or *Knot-root* (*Collinsonia*, G.; *Guérut-tout*, *Baume de cheval*, Fr.), is a native of eastern and central United States and extends into Canada. It is a perennial herb, about a meter (a yard) high. It has a nearly horizontal and irregularly branched rhizome, having, together with the branches, a length and width of 7 to 15 Cm. (3 to 6 In.), and on the upper side a very knotty and tuberculated appearance, from the numerous short projecting branches and the many shallow concave stem-scars; the lower surface is much less knotty, and bears many thin nearly simple roots or their remnants. It is externally of a grayish- or yellowish-brown color, has a very thin bark of a slight nauseous taste, and a very hard, whitish wood. The stem is quadrangular and hairy above; the leaves are opposite, petiolate, 7 to 20 Cm. (3 to 8 In.) long, thin, nearly smooth, ovate, pointed, sometimes rather heart-shaped at the base, coarsely serrate, and somewhat dotted beneath. The flowers are in loose racemes, of a lemon- to greenish-yellow color, the lower lip of the corolla fringed and with 2 exserted stamens. The fresh flowering herb has a delightful lemon-like fragrance; when rubbed, a strong and less agreeable odor. Its taste is pungent. Collinsonia is said to possess tonic, astringent, diuretic, and diaphoretic properties. The fresh root produces gastric irritation with nausea and vomiting. Hot infusions have been recommended in the treatment of fevers and muscular rheumatism; and cold decoctions made from the fresh root have been employed in the treatment of leucorrhœa, dropsy, gravel, and vesical catarrh.

FIG. 245.



Collinsonia (leaf, ⅓ Nat.; inflorescence, ⅔ Nat.).

C. ANISATA Sims (*Hypogon a.*—Raf.) is the *Anise-root* of our Southern States.

PERILLA FRUTESCENS (L.) Brit. (*Ocimum f.* L.; *P. ocimoides* L.), native and cultivated in India, is sparingly naturalized in the United States. The seeds, called *Kenia*, *Bhangara*, etc., are used as a food-grain in India. They contain 43 per cent. of fat, 10 per cent. of digestible carbohydrates, and 23 per cent. of albuminoids, and their nutritive ratio is as 1 : 5.

KOELLIA, Moench (*Pycnanthemum* Mx.), is a genus of about 15 species, most of them known as *Mountain mint*, with special prefixes. *K. flexuosa* (Walt.) MacM. (*Origanum f.*

Walt.; *Satureia Thymus-Virginicus* L.; *Pycnanthemum linifolium* Pursh.), the *Narrow-leaved mountain mint*, or *Virginia thyme*, has rigid, narrowly linear sessile crowded leaves, which are entire and 3-nerved; the flowers are in terminal hemispherical clusters, supported by imbricate, rigidly pointed bracts. It has been popularly regarded as useful in hydrophobia, and has been employed in atonic dyspepsia. Its tannin is very similar to, if not identical with caffeo-tannic acid. *K. Virginiana* (L.) MacMillan (*Satureia V.*—L.; *Pycnanthemum lanceolatum* Pursh.), *Virginia mountain mint*, *Virginia thyme*, *Mountain thyme*, *Prairie hyssop*, which extends west of the Mississippi, resembles the preceding, but the leaves are a little broader. Its oil can scarcely be distinguished from that of American Pennyroyal. *K. incana* (L.) Kuntze (*Clinopodium i.* L.; *Pycnanthemum i.* Mx.), the *Hoary mountain mint*, *Wild basil* or *Calamint*, incorrectly called "Horsemint," native of eastern United States, has broader, ovate-oblong, hoary-pubescent leaves.

MICROMERIA CHAMISSONIS (Benth.) Greene (*M. Douglassii* Benth.; *M. barbata* Fisch. et Meyer) is the *Yerba Buena* of the United States Pacific coast. It is a perennial creeping or trailing, sweet-scented herb of the Pacific coast from California to Washington Territory, and is known as *yerba buena*. The leaves are roundish-ovate, thin, sparingly toothed, and short-petioled; the purplish flowers are mostly solitary in the axils on long and filiform peduncles.

ORIGANUM VULGARE L., *Organy*, *Orgament*, *Wild*, *Winter*, or *Bitter marjoram*, *Winter-sweet*, *European mountain mint* (*Wilder Marjoran*, *Dosten*, *Gemeiner Wohlgemuth*, G.; *Origan vulgaire*, Fr.), is a perennial herb growing in dry soil throughout a large portion of Asia, Europe, and northern Africa. It has been introduced into the United States, where in some places it is now quite common. The stem is quadrangular, often purplish, branched above. The leaves are opposite, petiolate, roundish ovate, obtuse, entire, or slightly toothed, hairy on the veins beneath, and pellucid punctate. The flowers are terminal on the branches, forming a corymbose panicle, have a purple, ovate bell-shaped and 5-toothed calyx, a purplish somewhat 2-lipped corolla, and 4 didynamous exserted stamens. The leaves are oval to ovoid, rounded at the summit, 0.75 to 1 Mm. long and about two-thirds as broad, and are finely and harshly papillose. The herb has a strong aromatic, marjoram-like odor and a warm aromatic and bitterish taste. *O. Dictamnus* L., *Cretan dittany* (*Diptamdosten*, *Kretischer Diptam*, G.; *Dictame de Crete*, Fr.), native of the Levant, has woolly-tomentose, obtusely quadrangular branches, roundish ovate tomentose leaves, partly purple-colored bracts, and a dark-purplish corolla. It is pungently aromatic. *O. creticum* L., indigenous to southern Europe, bears the same names, and is known also as *Spanish hop* L., has hairy ovate or nearly cordate and somewhat 5-nerved, pungently aromatic leaves, and whitish flowers. In Europe the volatile oil is distilled from it, and is used like allied oils. The volatile oil of *O. hirtum* Link, which is often sold in place of it, consists, according to Jahns (1879), of 50 to 60 per cent. of *carvacrol* and of several terpenes, besides a volatile acid and a small quantity of a phenol which becomes violet-colored with ferric chloride. Some 20 species of *Origanum* are recorded as being medicinally employed. Wild marjoram has been recommended in the form of a poultice, for the treatment of sprains, bruises, and muscular rheumatism. A hot infusion is occasionally employed by the laity as a diaphoretic and emmenagogue.

FIG. 246.

Origanum (¾ Nat.); flower (× 3).

FIG. 247.

Majorana (¾ Nat.); flower (× 6).

MAJORANA MAJORANA (L.) Rusby (*Origanum m.* L., *M. hortensis* Moench.) yields *Herba majoranæ*, *H. amaraci* or *H. sampsuchi*, and is known as *Sweet*, *Garden*, or *Knotted marjoram* (*Meiran* or *Mayran*, *Majaran*, *Wurstkraut*, G.; *Marjolaine*, Fr.; *Majorana*, *Almoraduz*, Sp.). It is an annual herb, frequently cultivated for culinary purposes, and is indigenous to western Asia and southeastern Europe. The leaves are spatulate or oval, very obtuse, entire, gray-green, soft-hairy, and pellucid punctate. The flowers are aggregated in small heads and have a small whitish corolla. The plant is agreeably and pungently aromatic. The volatile oil (*Oleum majoranæ*) is thin, yellowish, of the specific gravity 0.89, boils above 163° C. (325.4° F.), is readily soluble in alcohol, has the aromatic odor of the herb, and, according to Beilstein and E. Wiegand (1882), contains a terpene boiling at 178° C. (352.4° F.) and forming a liquid compound with HCl; the fraction boiling between 200° and 220° C. (392° and 428° F.) has the composition $C_{15}H_{26}O$, and is not affected by metallic sodium. An ointment of marjoram, *Unguentum majoranæ*, is occa-

sionally employed; it is prepared by softening 2 parts of the cut herb with 1 part of alcohol, then digesting with 10 parts of lard until the alcohol has evaporated, straining and cooling. Sweet marjoram is employed by the laity in hot infusion for the purpose of hastening delayed exanthematous eruptions.

ROSMARINUS OFFICINALIS L. (*Rosemary* or *Old man*, E.; *Meerthau*, *Rosmarin*, G.; *Romarin*, Fr.; *Romero*, Sp.) is a native of southern Europe and cultivated, the drug largely collected and the oil distilled in Spain. It is shrubby, 0.9–1.2 M. (3 or 4 Ft.) high, much branched, evergreen, and has few-flowered axillary clusters of rather large pale-blue flowers. Rosemary leaves are about 25 Mm. (1 In.) long, leathery, linear, entire, sessile, obtuse at both ends, dark-green above, densely woolly and dotted with oil-glands beneath, and revolute on the margin. In drying, the margin becomes more strongly revolute, the leaf narrower and rigid, and the midrib prominent on the lower side. Rosemary has a peculiar aromatic, somewhat camphoraceous odor and a pungently aromatic taste. The principal constituent is the volatile oil. A little tannin, resin, and bitter principle are likewise present. Rosemary was formerly employed in warm infusion as an emmenagogue, galactagogue, and stimulant diuretic. A poultice made by steeping the leaves in hot water may be applied for the relief of local pains. At present it is occasionally employed as a carminative and diuretic, and is thought by some to be useful in functional nervous diseases. An infusion (2 drachms (8 Gm.) in 1 pint (480 Cc.)) may be given in doses of 4 fluidrachms (16 Cc.).

FIG. 248.

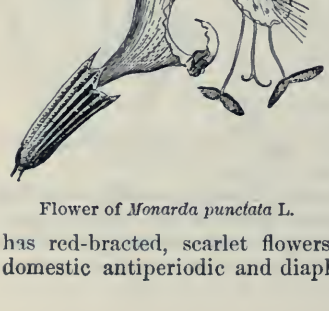
Rosmarinus officinalis L.: branch and flower.

LYCOPUS, L., is a genus of about a dozen species, several of which are largely employed. The principal species is *L. Virginicus* L., the *Virginian* or *Sweet bugleweed*, or *Wood betony* (*Virginische Wolfsfuss*, G.; *Lycope de Virginie*, Fr.), native of the eastern United States, flowering in late summer and fall. The stem is nearly smooth, about 30–45 Cm. (12–18 In.) high, obtusely quadrangular, and with slender runners at the base; the leaves are opposite, short-petioled, elliptic-lanceolate, toothed, wedge-shaped, and entire at the base, and glandular punctate beneath; the flowers are small, in axillary clusters, purplish, and have a calyx with 4 ovate and bluntish teeth. The herb has a somewhat mint-like odor and a bitter and slightly aromatic taste. *L. Europæus* L. (*L. aquaticus* Moench; *L. vulgaris* Pers.; *L. riparius* Salisb.) is the *Water* or *Marsh hoarhound*, *Bitter bugle*, *European bugleweed*, *Gypsy herb*, *Green archangel* (*Wasserandorn*, G.). It has been used in Europe as *Herba marrubii aquatici*. It is indigenous to Europe and North America, and resembles the bugleweed, being mainly distinguished by the often taller, sharply 4-angled stem, the more deeply and sinuate-toothed, at the base often pinnatifid, leaves, and the 5 triangular, sharp-pointed calyx-teeth. It varies somewhat in its foliage, and is not infrequently collected with the preceding. *L. Americanus* Muhl. (*L. sinuatus* Ell.; *L. Europæus sinuatus* A. Gray), *American bitter bugle*, *Paul's betony*, *Cut-leaved water hoarhound*, is very similar, and grows throughou North America.

CUNILA ORIGANOIDES (L.) Britton (*Satureja o.* L.; *Cunila Mariana* L.; *Hedyosmos origanoides* Kuntze) is *American* or *Mountain dittany*, *Wild Basil*, *Sweet horsemint*, *Stone mint*, *High pennyroyal*, native of the eastern United States, where it grows in dry soil, mostly on wooded hillsides. It has a thin, purplish, much-branched stem and nearly sessile, ovate, serrate, smooth leaves, which are rounded or subcordate at the base. The pale-purple flowers are in small pedunculate clusters and have 2 exserted stamens. Cunila may be employed as a diaphoretic for the same purposes as the other members of this family.

MONARDA, L., is a genus of about a dozen species, several of which are used under the name *Horsemint* or *Wild bergamot*. The plants are erect perennials, with toothed leaves and flowers in dense capitate heads terminating the branches, or in some species axillary as well. The calyx is narrowly tubular, 15-nerved, equally 5-toothed or nearly so, the corolla mostly glandular, strongly 2-lipped and ringent, the upper lip arched, the lower spreading. The inferior pair of stamens only bear anthers and are ascending, the thecæ divaricate. The most important is *M. punctata* L., *Common horsemint*, *American origanum* (*Pferdeminze*, G.; *Menthe de cheval*, Fr.), which has pale, spotted flowers, and extends beyond the Mississippi in the southern United States and is the source of *Monarda oil*. *M. didyma* L. (*M. coccinea* Mx.), the *American bee*, *Rose*, *Low*, *Red*, or *Scarlet balm*, *Oswego tea*, *Indian's plume*, is a native of eastern North America. It has red-bracted, scarlet flowers. *M. fistulosa* L. (*M. mollis* L.) is very similar, and is a domestic antiperiodic and diaphoretic in some sections. It has pinkish- or purplish-yellow,

FIG. 249.



Flower of *Monarda punctata* L.

white-bracted flowers. *M. citriodora* Cerv. (*M. aristata* Nutt.), of the southwestern United States, is the *Lemon monarda*, or *Prairie bergamot*. *Monarda punctata* is an aromatic stimulant, diaphoretic, and carminative, and is occasionally employed in domestic practice for the relief of flatulent colic, nausea and vomiting, and diarrhœa resulting from cold. The infusion (½ ounce or 16 Gm. to 1 pint or 480 Cc.) may be administered hot in doses of from 2 to 3 fluidounces (60–90 Cc.). Oil of horsemint may be locally applied to the skin for the relief of neuralgia and muscular rheumatism.

Calamintha is very similar to monarda and at least a dozen of its species are employed.

Hyssopus, *Hyssop*, *Garden hyssop* (*Ysop*, or *Isop*, *Eisering*, G.; *Hysope*, Fr.; *Hissopo*, Sp.), is the herbage of *H. officinalis* L. (*H. canescens* DC.; *H. orientalis* Adam), an herbaceous perennial, indigenous to southern Europe, frequently cultivated and sparingly naturalized in the United States. It is about 30 Cm. (1 Ft.) high, with wand-like simple quadrangular branches and opposite, sessile, linear-lanceolate, entire, and nearly obtuse leaves, which are about 25 Mm. (1 In.) long, nearly smooth, and finely punctate on both sides. The purplish-blue flowers are in small clusters, and have a 15-ribbed calyx, a 2-lipped corolla with a rather short and notched upper lip, and 4 exserted and divergent stamens. Hyssop has an aromatic somewhat camphoraceous odor and a pungent, aromatic, and bitterish taste. Aside from tannin, resin, fat, sugar, mucilage, etc., the most important constituent is *oil of hyssop*, of which the fresh herb yields 0.25 to 0.5 per cent. It is pale-yellow or greenish, limpid, of about the specific gravity 0.94, and freely soluble in alcohol; it contains oxygen, and commences to boil at 142° C. (287.6° F.), the boiling-point rising to 180° C. (356° F.). It has the odor and taste of the herb. The "hyssopin" of Herberger (1829) was found by Trommsdorff to be impure calcium sulphate. Mexican hyssop is *Salvia axillaris* Sesse. Hyssop is an aromatic stimulant and diaphoretic, which may be given in the form of an infusion as a remedy for dyspepsia, amenorrhœa resulting from cold, and muscular rheumatism. It has also been recommended in the treatment of chronic bronchitis, especially in old persons.

Dracocephalum.—Several species of this small genus are employed medicinally, and *D. Moldavica* L. is employed in Siberia as a substitute for tea.

Lophanthus rugosa Fisch. et Mey. is the Chinese aromatic *Hoh-hiang*, or *Hoh-ken*.

Nepeta is represented chiefly by the drug Cataria, elsewhere considered. To the same genus is often referred the *Ground ivy* or *Glechoma*, though it is more properly regarded as of a distinct genus. *Glechoma hederacea* L. (*Nepeta glechoma* Benth.; *N. hederacea* B. S. P.), *Ground ivy*, *Field balm*, *Cat's-foot*, *Alehoof*, *Gill-ale*, *Hove*, *Hay-maids*, incorrectly "Creeping Charlie" (*Gündelreben*, G.; *Lierre terrestre*, Fr.), is a native of Europe and very extensively naturalized in the United States. It is a slender, creeping, pubescent perennial herb, the leaves rather long-petioled, 1 to 4 Cm. (½ to 2 In.) broad, reniform-orbicular and deeply cordate; the flowers blue or violet, in axillary clusters, the calyx oblong, oblique, unequally 5-toothed, 15-nerved, the corolla dilated above, 2-lipped, the upper lip erect, 2-lobed, the lower spreading, 3-lobed, the large middle lobe notched. The taste is bitterish and aromatic.

Cedronella is a small genus, distinguished for the remarkably sweet fragrance of some of its species. *Cedronella triphylla* Moench (*Dracocephalum Canariense* L.), of the Canary Islands, is one of several plants used under the name *Sweet balm*. *C. Mexicana* Benth. and *C. pallida* Lindl. are used as substitutes for *Melissa* in Mexico.

Prunella (incorrectly "Brunella") vulgaris L. (*P. Canadensis* Mill.; *P. officinalis* Cranz) is the *Heal-all* or *Self-heal*, *Sickle-weed*, *Hook-weed*, *Carpenter's-herb*, *Brownwort*, E. (*Braunheil* or *Braunelle* G.; *Paquerette*, Fr.), widely distributed through the north-temperate zone, and common in fields, grassy places, and in woods in North America. Its ascending stem is about 30 Cm. (12 In.) long; the leaves are about 38 Mm. (1½ In.) long, petiolate, oblong-ovate, entire or somewhat toothed, and more or less hairy. The flowers are purplish-blue and form a dense leafy-bracted spike. The herb is nearly inodorous, and has a bitterish and somewhat astringent taste.

Ballota nigra L. (*B. fœtida* Lam.), *Herba ballotæ*, *H. marrubii nigræ*, *H. m. fœtidæ*, *Black*, *Stinking*, or *Bastard hoarhound*, *Black archangel*, *Dunnynettle*, *Henbit*, *Stinking Roger* (*Gemeine Ballote*, *Schwarzer Andorn*, G.; *Marube noir*, *Marube fœtide*, Fr.), is a native of Europe and seen occasionally in the United States. The stem is hairy, often red-brown; the leaves are wrinkled, hairy, ovate, slightly heart-shaped, acute, and crenately toothed. The reddish-purple flowers are in axillary clusters of 5 to 9.

Stachys, L., is a genus of nearly 200 species, a large number of which have been medicinally employed. The most important is *S. palustris* L., the *Hedge* or *Dead-nettle*, *Musk* or *Clown's woundwort*, *Rough-weed* or *Swine arnut* (*Stinknessel*, *Sumpfziest*, G.; *Ortie Rouge*, Fr.), native over a large part of the north-temperate zone, growing in moist places. It is stiff-hairy, and has nearly sessile, ovate-lanceolate, somewhat cordate leaves. *S. Fluminensis* Vell. is the *Catonga do mulata* of tropical America. *S. Betonica* Benth. is more generally known as *Betonica officinalis* L. It is the *Wood betony* or *Lousewort*, *Bishop's-wort*, *Wild hop* (*Betonie*, *Zehrkraut*, G.; *Betonie*, Fr.), native of Europe and occasional in the United States. It is rough-hairy, has cordate-oblong leaves, the cauline ones few, and purplish or whitish soft-hairy flowers in whorls of 6 to 10.

GALEOPSIS TETRAHIT L. (*G. grandiflora* Suter; *G. cannabina* Willd.), *Bee, Blind, Dog, Flowering,* or *Hemp nettle, Bastard hemp* or *Glidewort* (*Hanfnessel, Hohlzahn,* G.; *Chanvre Batard, Galeopside,* Fr.), is a native of the Old World and well established in many places in the United States. It yields the *Herba galeopsidis.* The stem is densely bristly, hairy below the joints; the leaves are ovate, usually acute, rather rounded at the base, coarsely serrate. The flowers are in dense axillary clusters, have long spiny-toothed calyx-teeth, and a white or yellowish corolla, with a purple spot on the lower lip. The allied species *G. ochroleuca* Lam. (*G. grandiflora* Roth.; *G. cannabina* Pollich), *Herba galeopsidis, Yellow hemp-nettle* (*Blankenheimer Thee, Liebersche Kraute, Gesundheitskraüter,* G.), native of Europe, at one time attracted attention as the principal ingredient of "Lieber's Consumption Herbs."

LEONURUS, L., is a genus of some 10 or 12 species of herbs. Most of them bear the name *Motherwort,* and the following are quite largely employed medicinally under that name: *L. Cardiaca* L. (*Cardiaca vulgaris* Moench), *Common motherwort, Lion's tail* or *Lion's ear, Cowthwort* (*Herzgespann, Wolfstrapp,* G.; *Cardiare, Agripanne,* Fr.), is native of temperate and subtropical Asia and Europe and quite commonly naturalized in the United States. It is 0.9 or 1.2 M. (3 or 4 Ft.) high, and has a quadrangular rather rough stem. The lower leaves are roundish, often heart-shaped at the base, and palmately 5- to 7-lobed; the upper ones are oblong, acutely 3-lobed, and have a wedge-shaped base. The pale-purplish flowers have awl-shaped or spiny-toothed calyx-teeth, and are in dense axillary cymules. The plant has a rather unpleasant aromatic odor and a bitter taste. It has been found to contain, besides volatile oil, a bitter principle, a hard and a soft resin, fat, wax, citric, tartaric, and malic acids. *L. Marrubiastrum* L. (*Cardiaca M. Medic.*), the *Hoarhound motherwort* or *Lion's tail,* etc.), has the same range. *Leonurus Sinensis* is the Chinese *Ch'nuy-wei* or *Yih-mu-ts'au.* Several species of *Siderotis* and of *Leonotis* are similar and similarly employed. Also various species of *Leucas,* much, and ignorantly, used for snake-bite.

LAMIUM, L., comprises 40 or 50 species, and a large number of them have been employed. The three following are most important: *L. album* L., *White, Blind, Dumb, Stingless nettle, Dead* or *Flowering nettle,* etc., *White archangel, Suck-bottle* (*Weisser Bienensang, Taubnessel,* G.; *Ortie blanche, Lamier,* Fr.), native of Europe, common in the United States. It has ovate, cordate, coarsely serrate, petioled leaves and white or whitish flowers, in dense axillary clusters. *L. amplexicaule* L. is the *Greater henbit. L. purpurea* L. is the *Red* or *Dead nettle,* etc., *Dry nettle, French nettle, Red* or *Sweet archangel.* The two last have roundish leaves and smaller, purplish flowers.

The genus TEUCRIUM, L., or *Germander,* comprises more than 100 species. The 20 or more of them recorded as in medicinal use have been much confused as to terminology. The genus is characterized by its flowers, which have the lower lip elongated and the upper lip short and deeply divided, the 4 stamens projecting from the cleft. All are aromatic and more or less bitter. The most important is probably *T. Marum* L. (*Herba mari veri, Herba thymi catariæ, Sea germander, Cat-thyme* or *Herb mastich,* E.; *Katzengamander, Amberkraut, Moschuskraut, Theriackraut,* G.; *Germandrée maritime,* Fr.; *Maro cortesso,* Sp.). It is shrubby, about 30 Cm. (12 In.) high and much branched. The leaves are about 8 Mm. (⅓ In.) long, petiolate, oval or lance-ovate, with the margin entire and revolute, and whitish-tomentose beneath. The rose-red flowers are single in the axils of the bracts, forming a 1-sided, spike-like raceme. The odor is strongly camphoraceous, the taste pungent and bitter. *T. Scordium* L. is the *Herba Scordii, Water germander, Wood garlic,* or *English treacle,* E. (*Wasserbathengel, Lachenknoblauch,* G.; *Germandrée aquatique,* Fr.; *Escordio,* Sp.). It is about 30 Cm. (12 In.) high, has sessile, lance-oblong, serrate, and soft hairy leaves about 33 Mm. (1.5 In.) long, and rose-colored flowers in whorls of 2 to 4. In the fresh state it has an alliaceous odor. Very similar is *T. Scordonia* L. (*Scordonia sylvestris* Link.), the *Wood germander, Garlic sage, Ambrose, European mountain sage. T. Polium* L. (*Polymountain,* E.; *Polium,* Fr.; *Bergpoley,* G.; *Zamarilla,* Sp.) has leaves 12 Mm. (0.5 In.) long, tomentose, sessile, lance-linear, obtuse, crenate, and strongly revolute on the margin. The flowers are white. The allied *T. montanum* L. has yellowish flowers. *T. Chamædrys* L., *Herba Chamædryos, H. trixaginis,* is the common *European* or *Wall germander* (*Chamædrys, Ground oak* or *Horse-chire,* E.; *Germanderlein, Edler, Frauenbiss,* G.; *Germandrée Chamædrys, Petit chene,* Fr.; *Camedrios,* Sp.). It is low, suffruticose, and branching. The leaves are about 25 Mm. (1 In.) long, petiolate, hairy, ovate or obovate, obtuse, cuneate at base, and crenately serrate. The flowers are purplish-red. *American germander* or *Wood sage* was formerly regarded as *T. Canadensis* L., but it is now known that several others were used under this name. The drug, as commonly employed, is downy or hairy, of a grayish-green color, and about 60 Cm. (2 Ft.) high. The leaves are about 5 Cm. (2 In.) long, short-stalked, lance-ovate, rounded at the base and serrate on the margin. The pale-purple flowers are in whorls of about 6 and form a terminal spike. The various members of this genus have been employed in the treatment of nervous cough, nervous depression, and functional nervous diseases. The dose of either variety is about 30 grains (2 Gm.), either in substance or in infusion.

AJUGA, L., of some 40 species, is an Old World genus, of which a dozen or more are employed medicinally under the name *Bugle. A. Chamæpitys* (L.) Schreb. (*Teucrium C.* L.),

the *European ground pine*, or *Field cypress*, and one of several plants called "Ground ivy" (*Feldcupresse, Günse*, G.; *Chamæpitys, Ivette*, Fr.; *Pinillo oloroso*, Sp.; *Kamafitus*, Persian), is a European small hairy annual with axillary flowers, having the yellow corolla dotted with purple; the lower leaves are lanceolate, the upper ones 3-cleft with linear lobes; the odor is rosemary-like. *A. Ivy* (L.) Schreb. (*Teucrium I.* L.), the *French ground pine* or *Ground ivy, Herb ivy, Gout ivy* (*Bisamgünsel*, G.; *Ivette musquée*, Fr.), resembles the preceding, but has linear, somewhat toothed, woolly leaves, red flowers, and a musk-like odor. This and the preceding species are official in the French Codex. *A. reptans* L., the *Common* or *Brown bugle, Sicklewort, Dead-man's bellows, Middle comfrey* (*Goldner Günsel*, G.; *Bugle*, Fr.), and *A. pyramidalis* L., the *Mountain* or *Erect bugle*, are small perennials, with obovate, crenate radical leaves, and blue flowers, slightly aromatic and somewhat bitter. The following additional drugs of this family are worthy of note: *Mangerona do campo*, of Paraguay, etc., is *Glechon spathulata* Benth. *Misk-i-trayamana*, of western Asia, is *Zizyphora clinopodioides* Lam. *Misk-i-turamashik* is *Z. tenuior* L. Both are musk-substitutes. *Yokwansa*, of Ceylon, is *Anisomeles ovata* R. Br. (*Nepeta Indica* L.; *N. Amboinica* L. f.). *Gajuban Mogbira*, of the East Indies, is *A. Malabarica* R. Br. (*Nepeta M.* L.; *Ajuga fruticosa* Roxb.). *Eremostachys tuberosa* Bge. (*Molucella t.* Pall.), of Tartary, yields an edible root, and *E. superba* Royle is used in India as a fish poison.

LAC FERMENTATUM.—Fermented Milk.

Kumyss, E.; *Lait fermenté*, Fr.; *Gegohrene Milch, Kumiss*, G.

Preparation.—Cows' milk, fresh, 1000 Cc.; yeast, semiliquid, 5 Cc.; sugar, 35 Gm. Dissolve the sugar in the milk, contained in a strong bottle, add the yeast, cork the bottle securely, and keep it at a temperature between 23° and 32° C. (73.4° to 89.6° F.) for 6 hours; then transfer it to a cold place.

The above formula, taken from the National Formulary, yields a satisfactory product. One-fourth of the quantity given, placed in strong 10-ounce bottles, will be found more desirable for sale and use.

In place of preparing kumyss with sweet milk, and waiting until it turns sour, the casein may be precipitated at once by the addition of one-third of ready kumyss to fresh milk. Yeast is not necessary, but sugar must be added to produce sufficient carbonic acid gas to cause effervescence.

Kumyss may also be made from sour milk, freed from its cream, by breaking up the curd by vigorous stirring, and causing alcoholic fermentation by addition of sugar and yeast. The cream removed may be replaced by sweet cream.

A similar preparation made from mares' milk has long been in use among the nomadic tribes of the Russian steppes. It is made with the aid of a peculiar ferment, occurring in large granules, and known as *Streptococcus kefir*. The resulting fermented liquid is known as *kefir, kephir*, or *kapir*.

Kephir-kumyss may be prepared by adding active kefir grains to fresh cows' milk, kept at a temperature of 70° to 80° F., until the effect of fermentation becomes apparent by the rising of the grains to the surface. The grains may then be strained off, and the milk, which now contains sufficient yeast-cells to insure continuance of the fermentation, left to itself in well-corked bottles.

Action and Uses.—Kumyss contains an altered casein, small quantities of alcohol, lactic acid, and carbon dioxide. This casein, which has been changed by the process of fermentation, is said to be more readily digested than that found in the milk from which this liquid is prepared. The alcohol and lactic acid materially aid digestion and the carbon dioxide is believed to increase the rapidity of absorption. When taken in large quantities, it quenches thirst, relieves hunger, increases nutrition, and slightly stimulates the circulatory, nervous, and respiratory systems. Because of the large quantity of water contained in kumyss, this beverage also increases the flow of the urine and the activity of the sweat-glands. It contains all of the virtues of milk, but as it is more easily digested and more rapidly absorbed, it may be given in larger quantities than the latter without producing the disagreeable sensation of weight in the epigastrium which frequently follows the ingestion of large amounts of other liquids. This preparation is especially useful in all forms of indigestion whether due to either depressions or irritability of the stomach. It is frequently employed as a food in enteric fever, and is useful as such in all typhoid states. As it promotes nutrition in general, it may be given with varying degrees of success in secondary anæmias and in chronic constitutional diseases.

LACCA.—Lac.

Resina lacca.—Lack, Gummi-lack, G.; *Laque, Gomme laque,* Fr.; *Goma laca,* Sp.

A resinous exudation from various plants, caused by punctures made by the hemipterous insect *Coccus lacca* Kerr.

Origin.—The East Indian trees yielding this substance are mostly milky-juiced plants, especially *Croton aromaticus* L. (*C. laccifera* L.; *Aleurites l.* Willd.—Fam. *Euphorbiaceæ*), the principal source, and *Ficus Indica* L. (the *Banyan* or *Indian fig*), *F. religiosa* L. (the *Pipal, Peepul, Bo* or *Sacred fig*), *F. Benghalensis* L., *F. Tájéla* Hamilt., and doubtless other species of Ficus (Fam. *Moraceæ*). Much Lacca is also yielded by *Schleichera trijuga* Willd. (*Cussambium spinosum* Buch-Hamilt.—Fam. *Sapindaceæ*). Other plants said to yield it are *Acacia Arabica* (see ACACIA) and *A. Greggii* A. Gray (Fam. *Mimosaceæ*), of the southwestern United States and Mexico, *Butea frondosa* Roxb. (Fam. *Leguminosæ*) and *Shorea Tálura* Roxb. (*S. laccifera* Heyne —Fam. *Dipterocarpaceæ*).

The impregnated female of the insect becomes imbedded in the exudation, through which the larvæ, if hatched, eat their way. Red Lac is that collected while it still retains the red coloring-matter developed by the body of the insect, and is the more valuable. The branches, bearing their incrustation, are collected.

Description.—The thin branches, almost completely covered with numerous small resin-nodules, constitute the *stick-lac.* The separate nodules or tears are red-brown, and contain in the interior a dark blackish-red powder; after the escape of the young insects the resin is brown. The same resin, after having been detached from the twigs, constitutes the *seed-lac* or *grain-lac.* It is in irregular fragments of the size of a pea and smaller, yellowish-brown or reddish, somewhat shiny, and nearly tasteless. After boiling the stick-lac or seed-lac with water, fusing the resin, and congealing it upon a smooth surface, *shellac* is obtained; it comes in thin, glossy, and more or less transparent fragments. Sometimes *grape-lac* and *lump-lac* have been distinguished, the former of which consists of agglutinated incrustations separated from the twigs; the latter is identical with shellac, except that it has not been congealed in thin layers. When chewed, stick-lac softens and colors the saliva purplish-red, a slight bitterish and astringent taste being perceived; when burned, it gives off a strong and agreeable odor. The water in which red stick-lac has been boiled on being treated with alum yields *lac-dye.*

Shellac is soluble in alcohol, potassa, soda, borax, and hydrochloric and acetic acids, and when digested with ammonia in closed vessels swells to a gelatinous mass. By treating the alkaline solution with chlorine or sulphurous acid, bleached shellac is obtained.

Constituents.—Lac is a complex body, containing, according to Unverdorben, 5 distinct resins, besides wax, fat, and coloring and extractive matter. The resins, which may be separated by their different behavior to alcohol, ether, and alkalies are present in seed-lac, according to Hatchett and John, to the amount of 66 or 68 per cent., but shellac contains fully 90 per cent. of resin. The wax has been found to vary in amount between about 2 and 6 per cent.

Action and Uses.—Lac is rarely employed in internal medicine. It may be combined with astringents and employed in the treatment of indolent ulcers.

LACMUS.—Litmus.

Lacca cærulea, Lacca musica.—Tournesol, Laque bleu, Fr.; *Lackmus,* G.

A blue pigment obtained from various species of lichens, such as *Leconora, Roccella, Variolaria,* and others found on the Azores, Canaries, and Cape Verde Islands, also in East India, Mozambique, Scotland, Sweden, and elsewhere.

Preparation.—The lichens are powdered, made into a soft pasty mixture with potassium carbonate, water, and stale urine, and exposed to the air to undergo fermentation. The liquid gradually acquires a red, purple, and finally blue color, and is then mixed with chalk, gypsum, or sand, to give it consistence, after which the mass is passed through a coarse sieve and moulded into small cakes or cubes, and finally dried. It is chiefly manufactured in Holland, and the best product is said to require about 40 days.

Constituents.—Besides mineral matter, litmus contains several coloring-matters, such as azolitmin, erythrolitmin, erythrolein, and spaniolitmin, the latter only in minute quantity. Of these, azolitmin is the most important. It is a weak acid, and exists in litmus in combination with potassium, insoluble in alcohol but soluble in water. Pure azolitmin is an amorphous brown-red substance. Erythrolitmin is a red crystalline body,

insoluble in ether but soluble in alcohol. The insoluble matter in litmus may range from 46 to 89 per cent., while the moisture present varies from 1.5 to 10 per cent.

D. Rainy Brown (*Pharm. Jour.*, 1896) examined 7 samples of commercial litmus, and found the proportion of azolitmin present to average 4.6 per cent., except in two cases in which it reached 13.3 and 14.1 per cent., respectively. Naturally the richer in azolitmin the more valuable is the litmus. Brown's method for determining the azolitmin content is as follows: "The finely powdered sample is exhausted with boiling water as long as any coloring-matter is extracted; the solution is evaporated to a small bulk, and after acidifying with acetic acid evaporation is continued nearly to dryness. The acetic acid converts the potassium and ammonium carbonates present into alcohol-soluble acetates. A large excess of 85 or 90 per cent. alcohol is added to the acidified solution, which precipitates crude azolitmin; after standing 12 hours the precipitate is collected on a filter, and when dry is dissolved in the smallest possible quantity of boiling water and poured into alcohol. After standing overnight the precipitate is filtered off, dried, and weighed.

Pharmaceutical Uses.—Litmus is used as a reagent or indicator for acids and alkalies, giving a red color with the former and a blue color with the latter. When used by gaslight, the change of color is best seen through green glass. Both litmus solution and litmus-paper are recognized in almost every pharmacopœia, although the directions for preparing the same are not uniform.

Tinctura Laccæ Musicæ.—*Litmus test-solution, Solution of litmus,* E.; *Soluté de laque bleu,* Fr.; *Lakmuslösung,* G.—This is prepared, according to the U. S. P., by exhausting coarsely powdered litmus with three separate and successive portions (representing about 4 times its weight) of boiling alcohol (to remove erythrolitmin), each extraction lasting for about 1 hour, and treating the residue with an equal weight of cold water so as to dissolve the excess of alkali present. Finally, extract the residue with about 5 times its weight of boiling water and filter. The Br. P. gives similar directions. 20 Gm. of litmus, in powder, are boiled for an hour with three portions, 80, 60, and 60 Cc. of 90 per cent. alcohol, after which the washed litmus is digested in 200 Cc. of distilled water and filtered.

Litmus solution should be preserved in wide-mouthed bottles closed with loose plugs of cotton to exclude dust, but to admit air.

Charta Exploratoria Cœrulea et Rubra.—*Blue and red litmus-paper,* E.; *Papier à tournesol bleu et rouge,* Fr.; *Blaues und rothes Lakmuspapier,* G.—Blue litmus-paper is made by impregnating strips of unglazed white paper with solution of litmus, and drying them suspended on clean twine in an atmosphere free from acid and ammoniacal vapors. The P. G. directs that the solution to be used shall be made by macerating litmus with 10 parts of water for 24 hours, occasionally rotating the vessel, then decanting and filtering. This solution is heated to boiling and diluted sulphuric acid added, drop by drop, until a small portion of the liquid diluted with 100 times its volume of water shows just a violet-blue color. Red litmus-paper is made by first changing the color of litmus solution to red by addition of just sufficient sulphuric or hydrochloric acid and then impregnating paper with the same as above directed.

Good sensitive litmus-paper should detect 1 part of sulphuric acid in 40,000 parts of water, 1 part of hydrochloric acid in 50,000, 1 part of potassium hydroxide in 20,000, and 1 part of ammonia in 60,000. It should be preserved in paper boxes or bottles protected against light, dust, and vapors.

Uses.—Litmus may be employed either in the form of an infusion or upon paper. Litmus paper is employed for determining the acidity or alkalinity of various fluids. Its most common use in medicine is in the examination of the urine. Its employment in the examination of the gastric contents is of little value, as it does not indicate either the variety or the amount of free acid present.

Allied Pigments.—Archil or *orchil,* E., *Orseille,* Fr., G., is made from the same lichens which yield litmus. The lichens are heated for a week with diluted ammonia, when sulphuric acid and table-salt are added. Archil is a pasty mass of a deep-purple color.

Persio.—*Cudbear,* E., *Orseille de terre,* Fr., *Persio, Rother Indigo,* G., is made in precisely the same manner, except that, instead of adding acid and salt, the mixture is dried and powdered. It occurs as a purplish-red powder and is used in the form of a hydro-alcoholic solution (see Tinctura Persionis) as a coloring agent in pharmaceutical preparations.

The lichens which are used for the production of the above pigments contain a number of chromogenes, which are ternary compounds, and in the presence of water and ammonia are converted into various nitrogenated red pigments. The most important of these chromogenes, as far as they have been investigated, are—*erythric acid*, $C_{20}H_{22}O_{20}$, *alpha-orsellic acid*, $C_{32}H_{28}O_{14}$, *beta-orsellic acid*, $C_{34}H_{32}O_{15}$, and *evernic acid*, $C_{34}H_{32}O_{14}$. On being boiled for a long time with water or alkaline solutions they yield *lecanoric acid*, $C_{16}H_{14}O_7$, afterward *orsellic acid*, $C_8H_8O_4$, and finally *orcin*, $C_7H_8O_2$, which crystallizes in large colorless needles, has a sweet taste, turns red on contact with air, and yields with ammonia *orcein*, $C_7H_7NO_3$; this is brown, and dissolves in alkalies with a beautiful red color. Orcin is also obtained from aloes by fusing it with caustic potassa.

LACTUCARIUM, *U. S., Fr. Cod.*—Lactucarium.

Lactucarium Anglicum, L. Germanicum.—*Giftlattichsaft*, G.; *Lactucarium*, G., Fr.; *Lactucario*, Sp.

The concrete milk-juice of *Lactuca virosa* L. (Fam. *Compositæ*).

The Lactucarium defined above, or some very similar substance, is official in most pharmacopœias. The French and Italian express the juice from the fresh stems, clarify and inspissate, while the Portuguese extracts the fresh stalks with 65 per cent. alcohol. The French and some others recognize an alcoholic extract of Lactucarium. The Belgian recognizes an alcoholic extract of the juice expressed from the stalks of *Lactuca sativa* L., the common garden lettuce, while some others clarify the same juice by a process of coagulation, expressing and inspissating the remaining juice, which is then called *Thridace*, a name which is also applied to the product of the same plant obtained like Lactucarium. The latter is also called *Lactucarium Gallicum*. Several pharmacopœias specify the product of *L. Scariola* L., the *Prickly lettuce, Horse thistle*, or *Compass plant* of Europe, occasionally found wild in the eastern and central United States.

Origin.—*Latuca virosa*, described below, is abundant in a wild state in western and southern Europe and occurs occasionally in America. It is also cultivated in Europe, mostly in England and Germany, for the production of Lactucarium. Collection is made by cutting off the top of the stalk, just as flowering is about to commence, and scraping off the exuding milk, which is dried by artificial heat, this process being complete in about 5 days. The same plant is cut half a dozen times daily, and the incisions are continued for several weeks. The average yield per plant is said to be from 40 to 50 grains, the juice yielding about 25 per cent. of its weight of Lactucarium. The substance is mostly inspissated in little dishes like evaporating-dishes, resulting in a plano-convex cake, this being cut into quarter segments in removing. Sometimes it is dried in double plano-circular cakes, and occasionally it occurs in irregular fragments.

Description.—In sections of plano-convex circular cakes, or in irregular, angular pieces, externally grayish-brown or dull reddish-brown, internally whitish or yellowish, of a waxy luster when cut; odor heavy, somewhat narcotic; taste bitter.

Lactucarium is partly soluble in alcohol and in ether. When triturated with water it yields a turbid mixture, and when boiled with water it softens and yields a brownish colored liquid which, after cooling, is not colored blue by iodine test-solution.

Tests.—Lactucarium on being treated with boiling water should become soft without melting, and yield a bitter filtrate, which while hot should be clear, and on cooling become turbid; this liquid should not be colored blue by iodine (absence of starch), but should become clear on the addition of ammonia or of alcohol; the ammoniacal liquid should yield a copious precipitate with solution of calcium sulphate (presence of oxalic acid), and the alcoholic solution should not be affected by ferric chloride (absence of tannin, etc.).

Several pharmacopœias place the ash limit at 10 per cent. The Dutch specifies that the drug should be dried over unslaked lime before powdering.

Composition.—*Lactucerin* or *lactucon* ($C_{28}H_{44}O_2$, Massner), the most abundant constituent, forms about one-half of the drug. It occurs in odorless, tasteless, white needles or conglomerates, soluble in hot alcohol, chloroform, ether, benzin, and oils, and insoluble in water. The bitter principles are lactucin, lactucic acid, and lactucopicrin, the rest of the drug including wax, caoutchouc, sugar, gum, pectin, soft resin, volatile oil, oxalic acid, and *alpha-* and *beta-lactucerol* (lactuceryl alcohol, $C_{18}H_{30}O$) in the form of acetates. These lactucerols with acetic acid are yielded on fusing lactucerin with potash. About 50 per cent. of lactucarium is soluble in water. *Lactucin* ($C_{11}H_{14}O_4$?) occurs in odor-

less, white, pearly scales or rhombic plates, soluble in 60–80 parts of water, slightly in ether, and readily in alcohol and acids. It is not a glucoside, but reduces Fehling's Solution. *Lactucic acid* is a light-yellow, very bitter body, crystallizable with difficulty, of acid reaction but without sour taste, and readily soluble in water and alcohol, its aqueous solution turning red with alkalies. *Lactucopicrin* ($C_{44}H_{32}O_{21}$) is brown, amorphous, of weakly acid reaction, very bitter, and easily soluble in water and alcohol.

Lactucarium contains no starch and no hyoscyamine, though the latter has been reported.

Pharmaceutical Preparations.—Fluidextract of Lactucarium, N. F.; Syrup of Lactucarium, Tincture of Lactucarium, U. S. P.

Action and Uses.—Lactucarium was formerly employed quite extensively as a soporific and sedative, but at the present time it is less frequently used. It may be given either in substance or in the form of a syrup for the relief of the nervous manifestations occurring during the course of certain infantile diseases. The dose of the powdered drug is from ½ to 2 grains (0.03–0.12 Gm.).

Allied Products.—Lactuca. Lettuce.—The genus *Lactuca*, L., comprises somewhere near 100 species, well illustrated by the common garden variety (*L. sativa* L.), which, although its physiological action is very mild, is somewhat employed medicinally (see above). It has been said, doubtless incorrectly, to contain a trace of hyoscyamine. As commonly employed in medicine and pharmacy, the name Lactuca or Lettuce (*Herba Lactucæ.—Giftlattich*, G.; *Laitue vireuse*, Fr. Cod.; *Lechuga*, Sp.) applies to the article official in the B. P., the flowering herb of *Lactuca virosa* L., the *Wild, Acrid,* or *Poison lettuce.* This is a biennial herb a yard or two high, the stem erect, somewhat prickly, the radical leaves large, petioled, oblong-obovate, obtuse, irregularly spinose-toothed, the midrib prickly, the stem-leaves gradually smaller, alternate, sessile or clasping, the apex spinose; inflorescence a loose terminal panicle; involucre oblong conical, the scales in about 3 rows, lanceolate, imbricate, the pale-yellow florets all ligulate; akenes oval, flattened, black with a long whitish beak, the pappus of numerous soft white capillary bristles; odor narcotic and disagreeable, and taste bitter and saline. Its constituents appear to be practically the same as those of the Lactucarium derived from it. Some other species have been found similar and probably most of them are so, and there is good reason to believe that related genera of the *Cichoriaceæ* also agree. The principal species which has been employed besides those mentioned above is *L. Scariola* L. Lettuce is rarely employed in medicine at the present time. In ancient times it was given as a soporific for the treatment of insomnia resulting from overstimulation of the mind. The variety grown in this country is practically devoid of soporific effect. In France a water distilled from the leaves is occasionally employed for its sedative effect, in doses of from 2 to 4 fluidounces (60–120 Cc.).

LAMELLÆ.—Disks.

Gelatina medicata in lamellis. Medicated gelatin disks, E.; *Disques de gélatine,* Fr.; *Gelatinlamellen, Gelatinplättchen,* G.

The name is applied to very small gelatin disks containing minute quantities of alkaloidal salts in solution. They may be prepared by dissolving the medicinal agent in an aqueous solution of gelatin to which glycerin has been added, and then pouring the finished solution upon perfectly smooth plates of glass or porcelain, which are set aside in a warm room, protected against dust, so that the moisture may evaporate. When dry, the sheet is divided by means of a suitable cutting apparatus into the required number of disks, each of which is about 1 Mm. ($\frac{1}{25}$ In.) thick and about 2.5 Mm. ($\frac{1}{10}$ In.) in diameter. The glycerin is added to prevent the disks from becoming hard and brittle on keeping.

Medicated gelatin disks are intended chiefly for use in ophthalmic treatment in place of solutions, and are introduced under the eyelid by means of a camel's-hair pencil. The Br. P. recognizes four kinds of medicated disks, and directs that, with one exception, they shall be of 0.0013 Gm. (about $\frac{1}{50}$ grain) weight, but gives no directions for their preparation.

Lamellæ Atropinæ, Br.—*Disks of atropine,* E.; *Disques d'atropine,* Fr.; *Atropinplättchen,* G.—Each disk is to contain 0.000013 Gm. ($\frac{1}{5000}$ grain) of atropine sulphate.

Lamellæ Cocainæ, Br.—*Disks of cocaine,* E.; *Disques de cocaine,* Fr.; *Cocainplättchen,* G.—Each disk is to weigh 0.00217 Gm. ($\frac{1}{30}$ grain) and contain 0.0013 Gm. ($\frac{1}{50}$ grain) of cocaine hydrochloride.

These disks are 4 times as strong as those of the Br. P. of 1885.

Lamellæ Homatropinæ, Br.—*Disks of homatropine,* E.; *Disques d'homatropine,* Fr.; *Homatropinplättchen,* G.—Each disk is to contain 0.0005 Gm. ($\frac{1}{100}$ grain) of homatropine hydrobromide.

Lamellæ Physostigminæ, Br.—*Disks of physostigmine,* E.; *Disques d'ésérine,* Fr.; *Physostigminplättchen,* G.—Each disk is to contain 0.00005 Gm. ($\frac{1}{1000}$ grain) of physostigmine sulphate.

LAMINARIA.—Laminaria.

Sea-girdle, Sea-staff, E.; *Laminaria, Riementang,* G.; *Laminaire digitée,* Fr.

The cylindrical base of the thallus of *Laminaria Cloustoni* Edmonst. and of *L. digitata* Lamour.

Origin.—These plants are very large sea-weeds of the North Atlantic and North Pacific, growing attached to rocks in from 10 to 15 fathoms of water. Their cylindrical base is somewhat rigid, their upper portion foliaceous and digitately lobed. The cylindrical portion is collected and quickly and carefully dried so as to avoid decomposition and the adherence of foreign matter.

Description.—In irregular, cylindrical pieces, about 12 Mm. (½ In.) or less thick, deeply wrinkled, externally brown or gray-brown, internally darker, of horn-like texture, and smooth horn-like fracture; softening and swelling to from 4 to 6 times its usual diameter when immersed in water; transverse section presenting an outer layer which is brownish and contains a zone of somewhat axially elongated large mucilage-cells, and a central portion of lighter or whitish color and composed of larger cells. It is prepared for medicinal use by being turned into evenly cylindrical or conical pieces.

Action and Uses.—Tents made of laminaria are employed principally for dilating the uterine cervix; occasionally, however, bougies are made of this material for the purpose of dilating strictures or sinuses. Their employment, especially in the uterus, is not unattended with danger, however, as they cannot be properly sterilized. Laminaria has largely fallen into disuse, as more efficient and less dangerous procedures have been adopted.

Allied Substances.—The soft spongy wood of *Nyssa grandidentata* Mx. f., the *Large tupelo, Cotton gum, Olivier,* and of *N. capitata* Walt., the *Tupelo gum, Sour gum,* or *Ogeechee lime* (Fam. *Cornaceæ*), both small trees of the southeastern United States, swells to nearly double its size when dry, upon immersion in water, and has been used similarly to Laminaria in gynæcological practice.

LAPPA, *U. S.*—Burdock.

Radix Bardanæ, P. A.—*Bazzies, Beggars' buttons, Cuckoo button, Hare-burr, etc.,* E.; *Klettenwurzel,* G.; *Bardane, Glouteron,* Fr.; *Bardana,* It., Sp.; *Lampazo,* Sp.; *Pegamaco,* Port.

The dried root of *Arctium Lappa* L. (*A. officinalis* All.; *Lappa o.* All.; *L. major* Gærtn.; *L. vulgaris* Neilr.; *L. tomentosa* Lam.) or of other species of *Arctium* (Fam. *Compositæ*), collected from plants of the first year's growth.

Lappa is official in most pharmacopœias, but these differ much as to the botanical names employed.

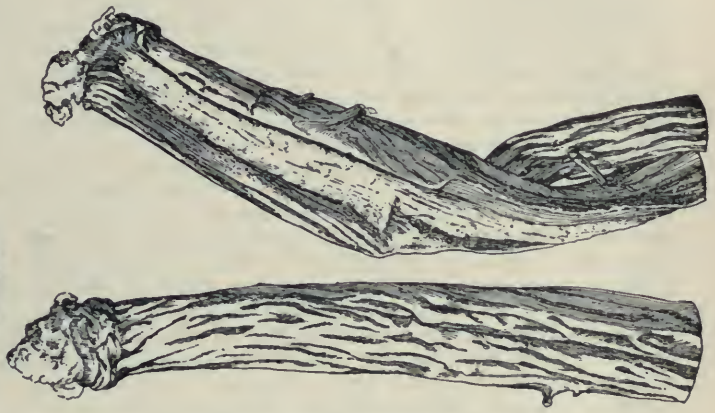
Origin.—The Burdocks are extremely coarse, biennial herbs of Europe and temperate Asia, now most thoroughly naturalized throughout North America and in other countries, in waste places, but in rich soil. The stems are of the second year's growth, are coarse and angular, 1 or 2 yards high, widely branching from the base, and bear enormous triangular-ovate, soft, grayish-white tomentose leaves on very thick, mostly reddish petioles, and racemose-paniculate heads which develop into globoidal burrs from ½ to 1 inch in diameter, clinging readily and tenaciously to passing bodies by their numerous involucral scales, which have recurved, hook-like tips. The florets are tubular, purple or rarely whitish. There has been great confusion regarding the specific and varietal forms and the application of the botanical names, but all forms of the root appear to agree in their almost complete inertness, from a medical standpoint. It is said that in Japan various forms are in cultivation for food, and that some of them reach a great size. For medicinal purposes, the roots are collected between the close of the growth of the first and the beginning of that of the second year. They weigh 6 or 7 times as much when fresh as when dry.

Description.—About 30 Cm. (12 In.) or more long, and 2 Cm. ($\frac{4}{5}$ In.) or less thick, nearly simple, very slenderly fusiform, bearing at the crown a soft, whitish, cottony tuft; or in broken pieces or longitudinal slices of the same, the edges of the longitudinal slices much incurved and usually rounded; externally grayish-brown to deep-brown, rather strongly longitudinally wrinkled; hard and with a short, somewhat fleshy fracture; internally, a dark cambium separates the brown bark from the yellowish wood, and the center is hollow or contains a whitish, pith-like tissue; free from starch; odor slight; taste mucilaginous, sweetish, slightly bitter.

FIG. 250.

Burdock root: transverse section.

FIG. 251.



Burdock: split and outer surfaces (Nat.).

The powder should be free from starch and calcium oxalate crystals.

Burdock root is quite liable to be wormy and mouldy, the latter contingency due to its fleshy nature and the difficulty of drying it.

Constituents.—Burdock root contains inulin, sugar, gum, mucilage, 0.4 per cent. of yellow fixed oil, wax, 0.075 per cent. of phlobaphene (altered tannin), and a very little *lappin*, a bitter crystalline glucoside, soluble in chloroform, alcohol, and water, and decomposed by very dilute acids into sugar and alcohol-soluble resin.

Pharmaceutical Preparation.—FLUIDEXTRACT OF LAPPA, U. S. P.

Action and Uses.—Burdock root may be employed as a diuretic and alterative in the treatment of gouty and rheumatic conditions, and in secondary syphilis and scrofula. It has also been employed as a remedy for chronic diseases of the skin; for example, acne and psoriasis. The fruit may be used as a substitute for the root, and the leaves are occasionally employed both internally and externally in the treatment of chronic skin lesions. Its administration should be continued over a period of several weeks to prove effectual. A decoction prepared by boiling 2 ounces (60 Gm.) of the root in 3 pints (1440 Cc.) of water until only 2 pints (960 Cc.) remain, may be given as the daily dose.

Allied Drugs.—FRUCTUS LAPPÆ, SEMEN BARDANÆ, *Burdock fruit*, is about 6 Mm. ($\frac{1}{4}$ In.) long, obovate-oblong, somewhat curved, angular, and flattened, roughish-wrinkled, brown-gray mottled with black, mostly deprived of the setaceous pappus, the short base of the style projecting from the center of the apical scar; inodorous; taste oily and very bitter. The fruit contains, according to Trimble and Macfarland (*Am. Jour. Phar.*, 1885, p. 127; 1888, p. 79), 15.4 per cent. of drying oil, 5.5 per cent. of resins, and a small quantity of the crystalline glucoside *lappin*. *Tinctura Lappæ Fructus* has been proposed to be made from 4 troyounces of the ground fruit by percolating with a mixture of alcohol 3 parts and water 1 part until a pint of percolate is obtained. Tincture of burdock fruit is frequently employed as a substitute for the preparations made from the root. It may be given in doses of from 1 to 2 fluidrachms (4–8 Cc.).

LAURACEÆ.—The Laurel Family.

This highly aromatic family is elsewhere represented in this work by the important drugs CINNAMOMUM, CAMPHORA, SASSAFRAS, COTO, and LAURUS. Very many of its 39 genera and 900 species possess constituents of equal activity, and are of less importance only because less

well known. Indeed, in the tropical regions of both hemispheres, its members, unknown to scientific medicine, contribute largely to the domestic materia medica. Some of the more important of these secondary drugs of the family are described below:

NECTANDRA BARK.—*Nectandræ cortex* (*Beeberu, Bibiru,* or *Bibiri bark, Green-heart bark,* E.; *Bibirurinde,* G.; *Écorce de bebeeru,* Fr.) is the dried bark of *Nectandra Rodiœi* Schombk., a large tree inhabiting the coast region of Guiana. The wood is strong and durable and highly valued for purposes where other woods are prone to decay; also in shipbuilding, since it is not attacked by marine parasites destructive to timber. It is generally stated in Guiana that wounds inflicted by the splinters of this wood are very apt to produce lockjaw. The bark is in flat or somewhat curved pieces, sometimes 30 to 60 Cm. (1–2 Ft.) long and 10 to 15 Cm. (4–6 In.) wide by 6 Mm. (¼ In.) thick, is heavy, hard, and brittle. The outer surface is gray-brown, with numerous irregular conchoidal depressions, the ridges between consisting of soft cork, sometimes with light reddish-gray patches containing small suberous warts. The inner surface is cinnamon-brown and rather coarsely striate. The bark breaks with a short and rough granular fracture, which is somewhat fibrous in the inner layer. It has no odor; its taste is astringent and persistently bitter.
